Some of our own countrymen have given credit to the submersion of swallows; and Klein patronizes this doctrine in his Hist. Av. 205, 206. But they assign no reason, why these birds are capable of enduring so long a submersion without being suffocated, or without decaying in an element so unnatural to them; when we know that the otter, the cormorant, and the grebes, soon perish, if caught under ice, or entangled in nets; and it is well known, that these animals will continue much longer under water than any others to whom nature hath denied that particular structure of heart, necessary for a long residence beneath that element. Mr. John Hunter, having dissected many swallows, found nothing in them different from other birds as to the organs of respiration; whereas all those animals which he had dissected, of the class that sleep during winter, such as lizards, frogs, &c. had a very different conformation in those organs. He farther adds his opinion, that these animals breathe in their torpid state; and, as far as his experience reaches, he knows they do; and he, therefore, esteems it a very wild opinion, that terrestrial animals can remain any long time under water without drowning.

There is another more probable opinion, with respect to the disappearance of swallows, which has high antiquity to support it. Aristotle and Pliny assert, that these birds do not remove very far from their summer habitation, but winter in the hollows of rocks, and during that time lose their feathers. We have had many late instances of some species of swallows having been discovered in a torpid state, on the cliffs of the Rhine, in old dry walls and sand-hills in Scotland, in the chalky cliffs of Sussex, in hollow trees, and lead mines, &c. These several places are supposed to be the lurking habitations of later hatches, or of those young birds that are incapable of distant *migrations*; where they generally continue insensible and rigid, though, like bats, they may sometimes be re-animated by an unseasonable hot day in the midst of winter. From these facts, it is reasonable to conclude, that, though one part of the swallow tribe migrates, others may have their winter-quarters nearer home. If it should be asked, why swallows alone are found in a torpid state, and not the many other species of soft-billed birds, which likewise disappear about the same time? the following reason, says Mr. Pennant, may be assigned. No birds are so much on the wing as swallows; none fly with so much rapidity and swiftness; none are obliged to such sudden and various evolutions in their flight; none are at such pains to take their prey; and none exert their voice more incessantly; whence they suffer a great expence of strength and spirits, and require such a texture of blood, as other animals do not experience; and become thus disposed to a more lasting repose than other birds. But notwithstanding this conclusion, it is most probable, that swallows in general, as well as other birds, migrate from colder into warmer climates, in search of proper food, a secure asylum from man during the time

of courtſhip, incubation, and nutrition, and a temperature of air ſuiting their conſtitutions.

The generality of birds that remain the winter with us, have ſtrong bills, or are enabled to feed on what they can find at that ſeaſon; thoſe which leave us, have uſually very ſlender bills, and their food is the inſects of the fly kind; which diſappearing towards the approach of winter, compel them to ſeek them in regions where they may be found; and the length of the wings of the generality of theſe birds, enables them to prey flying, if there be food for them in their way, and to continue a long time on the wing without reſt.

The various conjectures about the places to which they retire, are owing to want of ocular teſtimony; but if we conſider the vaſt tracts of land yet unknown to us, we cannot doubt but there may be many places for them, in which we can have had no opportunities of finding them. But the moſt probable conjecture ſeems, that the places to which they retire lie probably in the ſame latitude in the ſouthern hemiſphere, as the places from whence they depart; where, the ſeaſons reverſing, they may enjoy the like agreeable temperature of the air. And, if theſe places are ſuppoſed to be divided from them by two large ſeas, why may not ſome other parts of the ſouthern hemiſphere, which are leſs diſtant, ſerve their turn?

This, certainly, ſeems much more reaſonable than that they ſhould remain on our ſide of the northern tropic, within a few degrees of which, at the winter ſolſtice, it is ſo cold as frequently to produce ſnow; which, by diſperſing ſuch inſects as birds that feed upon the wing ſubſiſt on, muſt make them periſh, were they not to remove to thoſe warmer climates where they may ſtill find food. The ſwallows, as they cannot ſubſiſt ſo long in cold ſeaſons as ſome other birds of paſſage, which feed after the diſappearance of flies in the air, on what inſects they find in their receſſes, viſit us later, and depart from us ſooner, than the reſt. The nightingales, and ſome other birds, which leave us for the winter, are ſeen, ſometimes, a month after the ſwallows; and from the whole it ſeems natural to infer, that the ſwallows paſs the tropic of Cancer, though it is not yet known to what place they at length retire.

The manner of the birds of paſſage journeying to their ſouthern abode may vary, according to the different ſtructure of their bodies, and their power of ſupporting themſelves in the air. Thoſe birds with ſhort wings, ſuch as the redſtart, blackcap, &c. though they are incapable of ſuch long flights as the ſwallow, or of flying with ſo much celerity, yet may paſs to leſs diſtant places, and by ſlower movements. Swallows and cuckows may perform their paſſage in a very ſhort time; but there is for them no neceſſity for ſpeed, ſince every day's paſſage affords them an increaſe of warmth, and a continuance of food.

Providence, which has guided the defenceleſs animals in many other inſtances to the ſafeſt methods of performing their neceſſary works, may have inſtructed many of theſe birds which have ſhorter paſſages to make, or places to ſtop at by the way, to fly only in the night, that they may be ſecure from the birds of prey; and Mr. Cateſby gives a proof that ſome ſpecies do ſo, from his own obſervation; for, lying on the deck of a ſloop on the north ſide of Cuba, himſelf and the whole company heard, ſucceſſively, for three nights, flights of rice birds, which are eaſily diſtinguiſhed from all other birds by their notes, and which were paſſing over their heads northerly; which is their direct way from Cuba, and the ſouthern continent of America, from whence they got to Carolina, annually, about the time that rice begins to ripen, and from whence they return ſouthward again, when it is gathered, and they are become fat.

That this is the caſe alſo with ſome ſpecies of ſwallows, has been proved beyond contradiction by M. Adanſon, Hiſt. de Senegal, p. 67. We often obſerve them collected in innumerable flocks on churches, on rocks, and on trees, previous to their departure hence; and Mr. Colliſſon proves their return here, perhaps, in equal numbers, by two curious relations of undoubted credit; the one communicated to him by Mr. Wright, maſter of a ſhip, and the other by the late Sir Charles Wager; who both deſcribed to the ſame purpoſe what happened to each of them in their voyages. "Returning home," ſays Sir Charles, in the ſpring of the year, in I came "into ſoundings in our channel, a great flock of ſwallows came and ſettled upon my rigging; every rope "was covered; they hung on one another like a ſwarm "of bees; the decks and carving were fill'd with them. "They ſeemed almoſt famiſhed and ſpent, and were only "feathers and bones; but being recruited with a night's "reſt, took their flight in the morning." This apparent fatigue proves that they muſt have had a long journey, conſidering the amazing ſwiftneſs of theſe birds; ſo that in all probability they had croſſed the Atlantic ocean, and were returning from the ſhores of Senegal, or other parts of Africa.

The ſhort-winged birds are ſuppoſed little qualified for long flights, particularly the quail, which is a bird never ſeen long together on the wing, or making any long flights; as not doing this frequently is, however, no proof that it is not able to do it; nor does the ſtructure of its body at all beſpeak its inability; and Bellonius affirms, that he ſaw them in great flights paſſing over, and repaſſing, the Mediterranean ſea, at the very ſeaſons when they leave us, and they return again. The ſame inſtinct that directs theſe birds to depart to diſtant countries, doubtleſs alſo directs them to the ſhorteſt way, and ſends them to the narroweſt cuts, not the wider ſeas, to croſs.

Among the birds of paſſage, we have ſome alſo which come to us in the autumn, at the time when the ſummer birds are leaving us; and go from us again in the ſpring at the times when theſe return: theſe, however, are only four kinds; the fieldfare, the redwing, the woodcock, and the ſnipe; and of theſe the two laſt often continue with us through the ſummer, and breed; ſo that the two firſt ſeem the only kinds that certainly leave us at the approach of ſpring, retiring to more northern parts of the continent, where they live the ſummer, and breed; and, at the return of winter, are driven ſoutherly from thoſe frigid climes, in ſearch of food, which there the ice and ſnow muſt deprive them of. There are many others alſo, particularly of the duck or wading kind, that breed and make their ſummer abode in the deſolate ſenny parts of our iſland; and when the ſeverity of our winters deprives them of their food, neceſſity forces them to retire toward the ſea in numerous flights; where they find water unfrozen, and where they remain till the return of ſummer; but theſe cannot properly be called birds of paſſage.

It ſeems pretty evident from the whole, that the ſummer birds of paſſage leave us only in ſearch of a more warm climate, and a greater plenty of food; both which advantages they procure to themſelves by their alternate change of climate; but the *migration* of the winter birds of paſſage is not ſo eaſily accounted for, ſince there is no ſuch apparent neceſſity of their leaving us, either on the ſcore of food, or climate. The place of the ſummer retirement of theſe birds is Sweden, and ſome other countries in that latitude; but as they would find thoſe places too cold and deſtitute of proviſion, were they to ſettle immediately to them on their departure from us, they journey along gradually, and prolong their paſſage through the more moderate countries of Germany and Poland; by which means they do not arrive at their northern habitations, where they are to paſs their ſummer, and where they breed, till the ſeverity of the cold is ſo far abated as to render it pleaſing to them, and there is proper food there for them; and when they reviſit us the following winter, their journey is performed in the ſame leiſurely manner.

Sweden, and the other countries whence they come to us, ſeem the proper home of theſe birds; ſince there they were bred; and the journey they take to us being only for a warmer climate, and a plenty of food, it is no wonder that, when theſe benefits are to be expected again in their native place, they return to it.

The principal food of theſe birds, while with us, is the fruit of the white-thorn, or haws, which hang on our hedges, in winter, in prodigious plenty; but where they breed, and ſeem to live moſt at eaſe, as in Sweden, &c. there are no haws, nor indeed in many of the countries through which they journey in their way; ſo that it is evident they change their food in their paſſage. And upon the whole it appears, that Providence has created birds, &c. with conſtitutions and inclinations adapted to their different degrees of heat and cold; which, to them, are moſt agreeable, and to which they will travel from places which to other animals might ſeem more agreeable: by this means no part of the globe is without its inhabitants. Phil. Tranſ. vol. xliv. p. 435, &c. vol. ii. p. 459, &c. Pennant's Britiſh Zoology, vol. i. p. 406, &c. vol. ii. p. 709, &c.

MIGNONETTE, in *Botany*. See *Reſe*-ROCKET.

MIHA, in the *Materia Medica*, a name uſed by ſome authors for ſtyrax.

MILAX, a name by which *ſmilax* is often meant by the Greek writers.

MILDEW, *rubigo*, a diſeaſe happening to plants, cauſed by a dewy moiſture, which falling on them, and continuing, for want of the ſun's heat to draw it up, by its acrimony corrodes, gnaws, and ſpoils, the inmoſt ſubſtance of the plant, and hinders the circulation of the nutritive ſap: upon which the leaves begin to fade, and the bloſſoms and fruit are much prejudiced.

According to Cook and Mortimer, *mildew* is a thick, clammy

clammy vapour, exhaled in the spring and summer from plants, blossoms, and even from the earth itself, in close still weather, when there is neither sun enough to draw it on high, nor wind enough to disperse it. Hanging thus in the lower regions, when the evening's cold comes on, it condenses, and falls on the plants; by its thick clammy substance stops up their pores, and thus prevents perspiration, and hinders the sap from ascending to nourish the flowers, shoots, &c.

It is added, that this dew, falling on the top of a shoot of a cherry-tree about midsummer, has been found to stop the shoot; so that the tree has shot forth in other places. On plants which have smooth leaves, as the oak, &c. the dew hangs, and may be seen, tasted, &c. others, whose leaves are rougher, imbibe it. When it falls on wheat, &c. it spots the stems with a colour different from the natural one.

These dews, Mr. Mortimer takes to be the principal food of bees; being sweet, and easily convertible into honey. Some have supposed the blight and *mildew* to be both the same thing, but very erroneously. The *mildew*, properly so called, sometimes rests upon the leaves of trees in form of a fatty juice, and sometimes on the ears of corn; it is tough and viscous to the touch, and the sun's heat drying it up, it becomes yet more viscous and hard, and so daubs over the young grains in the ear, that they can never after expand themselves properly, nor grow to their due size or weight. Bearded wheat is less subject to the *mildew*, than the common sort; and it is observed, that newly dunged lands are more subject to the *mildew* than others. The most happy remedy for this is out of the farmer's power, but often happens naturally; this is a smart shower of rain, and immediately afterwards a brisk wind: this wholly disperses it. If the *mildew* is seen before the sun has any power, it has been recommended by many, to send two men into the field with a long cord, each holding one end, and drawing this along through the ears, the dew will be dislodged from them before the sun's heat is able to dry it to that viscous state in which it does the mischief. Some also say, that lands which have for many years been subject to *mildews*, have been cured of it by sowing soot with the corn, or immediately after it. See BLIGHT, DEW, HONEY-*Dew*, and *Perspiration of* PLANTS.

MILE, in *Geography*, a long measure, whereby the English, Italians, and some other nations, use to express the distance between places. See MEASURE.

In which sense *mile* is used to the same purpose with *league*, used by the French and other nations.

The *mile* is of different extent in different countries. The geographical or Italian *mile* contains a thousand geometrical paces, mille passus, whence the term *mile* is derived. The English *mile* consists of eight furlongs, each furlong of forty poles, and each pole of sixteen feet and a half: so that it is equal to one thousand seven hundred and fifty yards, or five thousand two hundred and eighty feet.

Cassinir has made a curious reduction of the *miles*, or leagues, of the several countries in Europe into Roman feet, which are equal to the Rhineland feet generally used throughout the North.

		Feet
The mile of Italy	——	5000
of England	——	5454
of Scotland	——	6000
of Sweden	——	30000
of Muscovy	——	3750
of Lithuania	——	18500
of Poland	——	19850
of Germany, the small		20000
The middle	——	22500
The largest	——	25000
of France	——	13750
of Spain	——	22970
of Burgundy	——	18000
of Flanders	——	20000
of Holland	——	21000
of Persia, called also parasanga		18750
of Egypt	——	25000

MILES, a Latin term, which, in its general import, signifies *soldier*.

In our English laws and customs, *miles* is peculiarly appropriated to a knight, called also *eques*.

MILIARENSIS, in *Antiquity*, a silver coin of the empire, substituted by Constantine in the room of the DENARIUS; and so called because he fixed the price of the pound of gold at 1000 pieces of this new silver. But as he divided the pound of gold also into 72 solidi, each solidus really contained 138 *miliarenses*, though it passed for 144; which difference between the real and current value of the SOLIDUS, in relation to the *miliarensis*, must have occasioned disputes in the payment of small sums. To remedy this inconvenience, it was thought proper to alter the weight of the silver money, and having fixed the price of the pound of silver at five solidi, to coin sixty pieces out of it, which retained the name *miliarensis*, though the pound of gold was worth but 864. It does not appear how many *miliarenses* Constantine coined of the pound of silver: but if the piece of gold was equally the same in his reign, as when five solidi were worth a pound of silver, the pound must have been worth 864 pounds of silver; and 1000 divided by 14¼ gives 69⅔ for the number of *miliarenses* coined out of the pound. Therefore it is probable, that Constantine's number was either 69 or 70. If the former, each piece should weigh 73⅔ Troy grains; if the latter 72,3. According to the former estimate, the proportion of gold to silver was almost 14½ to 1; according to the latter, 14 to 1. Phil. Trans. vol. lxi. part ii. p. 513. See FOLLIS.

MILFOIL. See YARROW.

MILFOIL, *water*. See *Water* VIOLET, MYRIOPHYLLUM, and UTRICULARIA.

MILIARIUM, the name of a tall and narrow vessel, used in the bathing of the ancients, for heating water to any degree, to give warmth to the rest. See Mem. Acad. Inscript. vol. i. p. 127.

MILIARY *fever*. See FEVER.

MILIARY *glands, vesicular* MILIARES, in *Anatomy*, a great number of small glands interspersed throughout the substance of the CUTIS, or skin.

The *miliary glands* are the organs whereby the matter of sweat, and insensible perspiration, is secreted from the blood.

They are interwoven with the pyramidal papillæ of the skin, and are each served with a branch of an artery, vein, and nerve; as also with a proper excretory duct, through which the fluid matter secreted from the blood in the substance of the gland, is excreted, and sent forth at the pores, or perforations, of the cuticle.

MILIARY *herpes*. See HERPES.

MILIOLUM, a word used by some medical writers to express a small tumor in the eye-lid, of the size and shape of the seed of a common millet.

MILITANT, a term understood of the body of Christians, while here on earth.

The Romanists divide the church into *militant*, patient, and triumphant: the *militant* is on earth; the patient, or passive, they place in purgatory; and the triumphant in heaven.

MILITARE *ærarium*. See ÆRARIUM.

MILITARIS *toga*. See TOGA.

MILITARIS *via*. See VIA.

MILITARY, something belonging to the *militia*, or soldiery. Thus,

MILITARY *architecture* denotes the art of fortification. See ARCHITECTURE, and FORTIFICATION.

MILITARY *art*, is the art or science of making or sustaining war to advantage. See WAR.

MILITARY *column*. See COLUMN.

MILITARY *court*. See COURT *of Chivalry*.

MILITARY *state* includes the whole of the soldiery; or such persons as are peculiarly appointed among the rest of the people for the safeguard and defence of the realm. See SOLDIER.

MILITARY *execution*, the delivery of a city or country up to be ravaged and destroyed by the soldiers, upon its refusing to pay contribution money. See EXECUTION.

MILITARY *exercises* are the evolutions or various manners of ranging and exercising soldiers. See EXERCISE.

MILITARY *feuds*. See FEUD.

MILITARY *fever*, a kind of malignant fever frequent in armies, by reason of the ill food, &c. of the soldiers. See FEVER, and HOSPITAL *Fever*.

MILITARY *government* is the supreme command and disposal of all the *military* power of a nation, by land and sea.

MILITARY *laws*. See LAW *of arms*, and MARTIAL.

MILITARY *machines*. See MACHINE.

MILITARY *order*. See ORDER, and KNIGHTHOOD.

MILITARY *pyrotechny*. See PYROTECHNY.

MILITARY *rewards*. See REWARDS.

MILITARY *tenures*. See TENURE.

MILITARY *testament*, among the Romans, was what we call a nuncupative will; or a testament made only by word of mouth, in the presence of two witnesses.

This was a privilege peculiar to the soldiery, and to them only when in the field; for at other times they were subject to the common laws in this respect. See SOLDIER.

MILITARY *ways*, *viæ militares*, are the large Roman roads, which Agrippa procured to be made through the empire, in the time of Augustus, for the more convenient marching of troops, and conveyance of carriages.

N. Bergier has wrote the history of the origin, progress, and

and amazing extent, of these *military roads*; which were paved from the gates of Rome to the extreme parts of the empire. See WAY.

MILITES *candidati*. See CANDIDATI.

MILITIA, a collective term, underſtood of the body of ſoldiers, or perſons who make profeſſion of arms.

The word comes from the Latin *miles*, *a ſoldier*; and *miles* from *mille*, which was anciently wrote *mile*. For in levying ſoldiers at Rome, as each tribe furniſhed a thouſand, *mille*, or *pile*, *men*; whoever was of that number, was called *miles*.

MILITIA, in its proper and more reſtrained ſenſe with us, is uſed to ſignify the inhabitants, or, as we call them, the *trained-bands*, of a town, or country; who arm themſelves, on a ſhort warning, for their own defence. In which ſenſe *militia* is oppoſed to regular ſtated forces. Soon after the reſtoration of king Charles II. when the military tenures were aboliſhed, it was thought proper to aſcertain the power of the *militia*, to recognize the ſole right of the crown to govern and command them, and to put the whole into a more regular method of military ſubordination; and the order in which the *militia* now ſtands by law, is principally built upon the ſtatutes which were then enacted, viz. 13 Car. II. cap. 6. 14 Car. II. cap. 3. 15 Car. II. cap. 4.

It is true the two laſt of them are apparently repealed; but many of their proviſions are re-enacted, with the addition of ſome new regulations, by the preſent *militia* laws; the general ſcheme of which is to diſcipline a certain number of the inhabitants of every county, choſen by lot, for three years, and officered by the LORD *lieutenant*, the deputy lieutenants, and other principal landholders, under a commiſſion from the crown. They are not compellable to march out of their counties, unleſs in caſe of invaſion or actual rebellion, nor in any caſe compellable to march out of the kingdom. They are to be exerciſed at ſtated times; and their diſcipline in general is liberal and eaſy; but when drawn out in actual ſervice, they are ſubject to the rigour of martial law, as neceſſary to keep them in order. This is the conſtitutional ſecurity, which our laws have provided for the public peace, and for protecting the realm againſt foreign or domeſtic violence, and which the ſtatutes 2 Geo. III. cap. 20. &c. 2 Geo. III. cap. 42. declare is eſſentially neceſſary to the ſafety and proſperity of the kingdom. Blackſt. Com. book i. p. 411, &c.

By the 2 Geo. III. cap. 20. all former acts relating to the raiſing of the *militia* are repealed, except in ſuch caſes as are therein ſpecially directed to be ſubject to the proviſions of the former acts, or any of them; particularly with regard to the city of London, the Tower Hamlets, and the Cinque Ports. The ſtatutes now in force, relating to the *militia*, excluſive of the annual acts concerning their cloathing and pay, are the following: 2 Geo. III. cap. 20. 3 Geo. III. cap. 10. 4 Geo. III. cap. 17. 5 Geo. III. cap. 34. 5 Geo. III. cap. 36. 6 Geo. III. cap. 20. 7 Geo. III. cap. 17. 9 Geo. III. cap. 42. 10 Geo. III. cap. 9. 11 Geo. III. cap. 32. 16 Geo. III. cap. 9. 18 Geo. III. cap. 59. 19 Geo. III. cap. 44. 19 Geo. III. cap. 72. 19 Geo. III. cap. 76.

The whole number of private men to be raiſed, excluſive of certain places that are excepted, is 30,740; in various proportions for the ſeveral counties. The perſons exempted from ſerving in the *militia*, or providing ſubſtitutes, are peers of this realm; commiſſioned officers in his majeſty's other forces, or in any of his caſtles or forts; non-commiſſioned officers and private men ſerving in any of his majeſty's other forces; commiſſioned officers ſerving, or who have ſerved four years in the *militia*; members of either of the univerſities; clergymen; licenſed teachers of any ſeparate congregations; conſtables, or other ſuch peace officers; articled clerks, apprentices, ſeamen, or ſea-faring men; perſons muſtering and doing duty in any of his majeſty's dock-yards; perſons free of the company of watermen of the river Thames; perſons employed and muſtered at the Tower of London, Woolwich Warren, the ſeveral gun-wharfs at Portſmouth, Chatham, Sheerneſs, and Plymouth, or at the powder mills, magazines, or the houſes under the direction of the board of ordnance; and poor men who have three children born in wedlock. Perſons balloted, that refuſe to ſerve or provide a ſubſtitute, ſhall forfeit 10*l.* and at the expiration of three years, be liable to ſerve again, in perſon or by ſubſtitute. Thoſe who have ſerved are to be returned home in due time, ſo that they may reach the county to which they belong, if abſent from it, by the expiration of their term; unleſs they ſhall conſent to ſerve again. The enliſting of perſons enrolled to ſerve in the *militia*, for ſervice in his majeſty's other forces, ſhall be deemed null and void. The *militia* are required to be trained and exerciſed by regiment or battalion, twice in a year, fourteen days at each time, or once in a year, for twenty-eight days together: and the penalty of not appearing, or deſerting, is the immediate payment of 20*l.* or impriſonment for ſix months, or till the money is paid. In caſe of actual invaſion or immediate danger of it, or rebellion in this kingdom, his majeſty, communicating the occaſion to parliament, if ſitting, or declared in council, and notified by proclamation, if parliament be not ſitting, may order the *militia* to be embodied, put under the command of general officers, and led to any part of the kingdom, but not to go out of it; and they ſhall be ſubject to the acts againſt mutiny and deſertion. And any perſon not appearing, ſhall forfeit 40*l.* or be impriſoned for twelve months. Officers of the *militia*, during the time of ſervice, are exempted from the office of ſheriff; and private men from highway duty, from pariſh offices, and ſerving in his majeſty's other forces by ſea or land. *Militia* men, when ſick, are entitled to relief; and their deſtitute families to a weekly allowance out of the poor rates of the pariſh, &c. to which they belong. If they are maimed or wounded in actual ſervice, they are intitled to the benefit of Cheſſea-hoſpital: they may ſet up trades in any part of the kingdom.

MILITUM *curia*. See CURIA.

MILITUM *expenſa levandis*. See EXPENSÆ.

MILIUM, in *Botany*. See MILLET.

MILIUM *ſaxatile*, in *Botany*, a name by which ſome authors call the lacryma Jobi, or Job's tears.

MILIUM *Indicum*, in *Botany*, a name by which ſome authors call the maize, or Indian wheat.

MILK, *lac*, a white juice, or humour, which nature prepares in the breaſts of women, and in the udders of other animals; for the nouriſhment of their young.

Milk is thicker, ſweeter, and whiter, than the chyle itſelf, from which it is derived; and that, probably, without much more artifice or alteration than the leaving behind ſome of its aqueous parts.

The ancients held it formed from the blood; but the moderns are of opinion it comes from the pure chyle, conveyed by the arteries to the breaſts, and without any other coction filtrated through the glands whereof they are compoſed, like urine through the reins; without undergoing any conſiderable change.

According to M. Leeuwenhoeck's obſervations, *milk* conſiſts of little globules ſwimming in a clear tranſparent liquor, called *ſerum*, or *whey*.

Milk is a compoſition of three different kinds of parts; butyrous, caſeous, and ſerous. The *butyrous* parts are the cream and oil that ſwim at the top, and give it an opake white colour; the *caſeous* are the groſſer parts, which ſerve as a mucilage to keep the oily part ſuſpended, and thoſe that coagulate, and are made into cheeſe; the *ſerous* are properly a lympha, and theſe make what we call a *whey*, ſerving as a vehicle for the other two. So that *milk* may be juſtly called an animal emulſion. In its pure ſtate, it diſcovers no marks of any acid or alkaline quality: its taſte is agreeable and ſweet; it contains none or very few parts, that are volatile with the heat of boiling water: and its ſmell is very weak. It is eaſily acted upon and coagulated by the ſmalleſt quantity of acid, and alſo by the mixture of an alkali, which gives it a ſponeceous quality. *Milk* is alſo ſuſceptible of a ſpontaneous fermentation, by which it becomes acid, and is coagulated. But this ſpontaneous curdling and acidity are avoided, in the making of cheeſe for aliment, or whey for medicine, by mixing with the *milk*, before it has become too old, the ſmalleſt quantity of acid neceſſary for coagulation, and by accelerating this coagulation with a convenient heat.

Dr. Drake ſays, that *milk* is nothing but oil and water united by the artifice of nature, perhaps by the intervention of ſome peculiar ſalts, which *milk* itſelf, however ſweet at firſt, does, after a little ſtanding, diſcover to be pretty plentifully therein.

The whey of *milk* contains, beſides a ſaccharine fermentable ſubſtance, ſeveral kinds of ſalts, which may be obtained by cryſtallization. If three-fourths of clarified whey be evaporated, and the remainder ſet in a cool place, a certain quantity of reddiſh cryſtals will be formed: this is the eſſential *ſalt of milk*. It is called the *ſugar of milk* from its taſte, which is manifeſtly ſaccharine. If the cryſtals are well drained, diſſolved in pure water, and cryſtallized, they will be much whiter and leſs ſaccharine. By repeating the operation, the cryſtals may be rendered perfectly white and almoſt taſteleſs.

Or, the ſalt of *milk*, may be prepared by boiling whey to one half, then filtrating it; the coction and filtration are to be continued, till the liquor becomes of the conſiſtence of a ſyrup. This being put into a cellar to cryſtallize, the ſalt will be formed into a cake of a ſaccharine taſte, reſembling manna.

This preparation is Dr. Gaubius's, and is ſomewhat different from that which Valentini, in his Medicina Nov. Antiq.

Antiq. alledges to be the famous facchiarum laëtis, fo much cried up by Lodovicus Feſti, and recommended by others as an infallible cure for the gout. Med. Eſſ. Edinb.

Milk is found in the breaſts of women after they have been pregnant about four months. The fermentation of the *milk* in the breaſts, the firſt day after a woman is delivered, often occaſions a fever, which takes its name therefrom.

The colour of ſaffron, the bitterneſs of wormwood, and the ſmell of garlic are given to the *milk* of a woman who eats theſe plants; and alſo the purgative and inebriating efforts of certain ſubſtances are communicated from a nurſe to the child. See *Women's* MILK.

Ariſtotle ſays, there are ſome men who have *milk* in their breaſts. Cardan tells us, he ſaw one that had enough to ſuckle a child.

In the Philoſophical Tranſactions, we have an account of a wether brought to *milk* by the ſucking of a lamb; which lamb was maintained by it all the ſummer, till it was weaned.

Milk, corrupted in the ſtomachs of children, occaſions moſt of the diſeaſes incident to that age. Dobel, a Daniſh phyſician, who has wrote expreſly on this ſubject, tells us, an excellent remedy in ſuch caſe is, a glaſs of water with a little ſalt diſſolved in it: this acts as an emetic, and throws up the matter that occaſioned the diſorder. Celſus alſo mentions this remedy.

Galen obſerves, that, in animals fed with *milk*, the greateſt part of the food of the mother is, for that time, converted into that humour.

Hoffman found, by experiments, that the *milk* of cows and of goats contained more of the butyraceous and caſeous, and leſs of the ſerous and of the ſaccharine particles, than human *milk*, and the *milk* of aſſes.

There are ſeveral kinds of *milk*, uſed not only as food, but as phyſic: as cows *milk*, aſſes *milk*, mares *milk*, sheeps *milk*, and goats *milk*. Theſe are preſcribed as proper to alter a ſtrong thin blood into a craſis more ſoft, balſamic, and nutritive; and in conſtitutions where they ſit the firſt paſſages, they muſt be very good for that end, as being ready prepared into nutriment, ſo far as is required for their admiſſion into the blood: but where the juices of the ſtomach are ſharp, theſe liquors are apt to be turned into curd. Whenever *milk*, therefore, of what kind ſoever, is ordered in conſumptions, and as a reſtorative, it is with good reaſon joined with the teſtaceous powders, and ſuch things as are proper to deſtroy thoſe acidities.

Aſſes *milk* is ſaid to be a great beautifier and preſerver of the ſkin. Poppæa, wife of the emperor Nero, uſed it for that purpoſe; having four or five hundred aſſes conſtantly in her retinue, to furniſh her every morning with a freſh bath.

Milk is evidently one of the beſt nouriſhments of the body; and it is not wonderful that it ſhould prove ſo, when we conſider that in all caſes of nouriſhment the proximate matter taken to nouriſh ought to be as like as may be to the body to be nouriſhed by it. We ſubſiſt by the ſame things by which we are generated, and even while in the ſtate of a fœtus in the womb, we are nouriſhed not by blood, as ſome ſuppoſe, but by a lacteous juice, which is ſeparated from the blood in the uterus by means of the placenta, as it is in the breaſts of women who give ſuck, by glandules and tubuli deſtined for that purpoſe. Meats which we daily feed upon paſs down into the ſtomach indeed in their own form, but they do not nouriſh us till they are changed into chyle, or a milky liquor.

Milk being analyſed is found to be compoſed of fatty, ſerous, and terreſtrial parts; and theſe its conſtituent principles being eaſily mixed and ſeparated again, are made of it matter for the nouriſhment of the different parts of the body. The ſerous part, which is alſo nitrous, being a proper vehicle to convey through the veſſels the fatty parts, which are as well adapted to all the offices of nutrition as any ſubſtance can be.

It is eaſy to infer from this account of *milk* that it is not only a proper food for children, but for grown people alſo; but proper regulations are to be obſerved as to its uſe in particular caſes; no aliment any more than this being capable of ſuiting all conſtitutions and circumſtances. Meat in the ſtomach is converted into chyle, or a ſubſtance like *milk*; this chyle paſſes into the heart through the blood-veſſels, and its fineſt and moſt ſpirituous parts are there tranſmuted into the red part of the blood; and after this the groſſer parts of it are by different elaborations tranſformed into bile, and the ſeveral other humours in the body. It is evident that theſe humours, as well as the blood itſelf, muſt all have a ſupply; and that meat cannot give this ſupply, till it is converted into chyle or *milk*; how much labour then is ſaved the animal functions by giving at once into the ſtomach chyle ready formed, that is *milk*; and in caſes where the action or juices of that organ are ſo debilitated as not to be of power to convert the meat into chyle, what remains but that the perſon muſt die ſlowly, by want of the ſupplies of the ſeveral fluids of the body, if ſomething be not given that is capable of paſſing into the blood with leſs preparation than meats are; and what is ſo proper on ſuch an occaſion as *milk*, which is already ſo much allied to the nature of the fluid that ſhould have been chiefly ſeparated from meat, that it will readily ſupply all other?

Milk is apt to occaſion one or two very oppoſite diſorders, fluxes and coſtiveneſs. This is remedied by diluting it with water, or by proper correctives, or by chuſing that kind of *milk* which beſt ſuits the conſtitution, and the diſeaſes to be treated. E. gr. The *milk* of goats has been found to ſuit better than cow's *milk* with thoſe perſons, whoſe conſtitutions diſpoſe them to diarrhœas.

Milk-diet is uſeful in the GOUT and STONE.

Dr. Cheyne recommends *milk* and ſeed diet with water for drink, as the ſureſt preſervative againſt diſeaſes, and cure of them. See CANCER, PALSY, FITS, GOUT, and STONE.

Upon opening a vein, eſpecially after meals, *milk* is ſometimes found inſtead of blood. See Phil. Tranſ. N° 6. p. 100.

We have ſeveral mineral *milks*, and ſome artificial ones, ſo called from their reſemblance of the natural. As,

MILK *of the moon, lac lunæ*, a name given by naturaliſts to ſoſſil agaric, a white light marle. See LAC *lunæ*.

Some ſay, it is chiefly found in ſilver mines, and that it is a flower ſublimed from the ore of that metal; whence its denomination, *flower of ſilver*.

MILK *of ſulphur, lac ſulphuris*, a preparation of flowers of ſulphur, and ſalt of tartar; preſcribed by phyſicians, as a ſudorific. See SULPHUR *præcipitatum*.

MILK-*water*. See WATER.

MILK, *virgin's, lac virginale*, compoſed of roch alum, ſpring-water, litharge, and vinegar; uſed as a coſmetic, to drive in pimples, and check any cutaneous eruptions, by its cooling, reſtringent quality.

MILK, in the *Wine Trade*. The coopers know very well the uſe of ſkimmed *milk*, which makes an innocent and efficacious forcing for the fining down of all white wines, ſtracks, and ſmall ſpirits; but is by no means to be uſed for red wines, becauſe it diſcharges their colour. Thus, if a few quarts of well-ſkimmed *milk* be put to a hogſhead of red wine, it will ſoon precipitate the greater part of the colour, and leave the whole nearly white; and this is of known uſe in the turning red wines, when pricked, into white; in which a ſmall degree of acidity is not ſo much perceived.

Milk is, from this quality of diſcharging colour from wines of uſe alſo to the wine-coopers, for the whitening of wines that have acquired a brown colour from the caſk, or from having been haſtily boiled before fermenting; for the addition of a little ſkimmed milk in theſe caſes, precipitates the brown colour, and leaves the wines almoſt limpid, or of what they call a water whiteneſs, which is much coveted abroad in wines, as well as in brandies.

MILK, *women's*. The *milk* is often a very troubleſome and dangerous thing to women in their lyings-in, and ſubjects them to many painful diſorders. About the third or fourth day after delivery they are uſually affected with chilneſſes and ſhiverings, which are well known to be owing to that cauſe, and are therefore not to be treated as a diſeaſe, nor any medicines to be given in them; only it is proper to keep the perſon warm, and promote perſpiration, eſpecially in the breaſts. Sometimes indeed this ſymptom is joined with a febrile heat, or a real *inflammatory* FEVER, which is then to be taken off by the proper means.

The *milk*-fever, to which women are ſometimes ſubject after delivery, is partly owing to the abſurd cuſtom that prevails, of not putting the child to the breaſt for the firſt two or three days, till the *milk* flows freely of itſelf. The more immediate cauſes of this diſorder are a diſtention of the nerves in the breaſt, and an abſorption of the *milk* which hath become acrid by ſtagnating in the breaſts for want of being drawn either by the child or from the perſon. In this caſe, the fafeſt courſe is plentiful [illegible] gentle evacuations, and fomentations of [illegible] ed: a thin cooling diet ſhould be uſed, till the violence of the ſymptoms is abated. See *Miſbirth* FEVER.

Hoffman obſerves, that this fever of child-bed women might be prevented, if they, during their pregnancy, were regular in their diet, uſed moderate exerciſe, took now and then a gentle laxative of manna, rhubarb, or cream of tartar, not forgetting to bleed in the firſt months, and avoid all ſharp air. When the labour is coming on, it is not to be haſtened with forcing medicines, which inflame the blood and humours, or put them into unnatural commotions. Care ſhould alſo be taken, after the

the birth, that the natural excretions proceed regularly, and, if the pulſe be quick, a little nitrous powder or ſome other cooling medicines ſhould be adminiſtered.

Very frequently there come on inflammations of the breaſts, of the eryſipelous kind; theſe are uſually taken off by the external uſe of ſpirit of wine and camphor with a little ſaffron in it, by embrocating them with a little warm linſeed oil, or applying to them the leaves of red cabbage, and by carefully keeping the parts warm. See TUMORS *of the Breaſts*.

The *milk* often proves very difficult to be drawn out; this is to be helped by keeping the body carefully open by carminative and emollient clyſters, by keeping up a gentle diaphoreſis, and by attemperating medicines mixed with the milder alexipharmics. The breaſts are all the time to be kept carefully covered with flannel, and gently preſſed and rubbed at times; and finally they are to be drawn by means of a pipe, or by the mouth of an experienced perſon.

Every mother who has *milk* in her breaſts, ought either to ſuckle her own child, or to have her breaſts frequently drawn, at leaſt for the firſt month; this would prevent many of the diſeaſes which prove fatal to women in child-bed.

MILK, *deficiency of*, is alſo a very common complaint, and it is in ſome caſes abſolute, there being no *milk* at all derived into the breaſts; in others, it is only a partial one, there being ſome *milk*, though not enough to ſupply the child with nouriſhment. A total deficiency of *milk* moſt frequently happens to perſons who have their firſt child when ſomewhat advanced in years, and to ſuch as are of a choleric diſpoſition; but a partial deficiency of it is often owing to a faltneſs of the ſerum, and ſometimes to the want of nouriſhment, and often is brought on by ſorrow.

When ſaline and bilious humours are in fault, then lac lunæ, calcined cryſtal, and other abſorbent powders, become of great uſe: ſome alſo preferibe the powder of earth-worms carefully dried, and the voiding the humours by ſtool, by means of gentle purges: when a want of nouriſhment is the only occaſion of it, the *milk* may always be recovered in a proper quantity by means of good foods, with *milk* and other nouriſhing fluids.

MILK, *an over-abundance of*, is as common a complaint, as a deficiency of it, and requires as much care in the treatment, otherwiſe the perſon is frequently ſubject to nodes and abſceſſes in the breaſt. The proper remedies are the eating and drinking more ſparingly, and the letting two children ſuck inſtead of one.

Many people do not ſuckle their children, and therefore find it neceſſary to drive away their *milk* abſolutely. This is beſt done by taking internally the digeſtive ſalts, with diaphoretic and diuretic medicines. Externally, it is proper to apply to the breaſts bags of the dried leaves of parſley, mint, cherril, &c. with the ſeeds of coriander and parſley, and a little camphor; and ſpirit of wine with camphor, and a little ſaffron is to be rubbed in, or linen rags wetted in it and applied. Cerates may alſo be made of white wax melted in oil of almonds, with a little camphor, and applied to the breaſts freſh every morning and evening, or oftener, if neceſſary.

MILK, *a too great thinneſs of the*, is another common complaint with nurſes; this is to be laid ſometimes to the diet, ſometimes to the concoction, and ſometimes to the unnatural tenuity of the humours; in this caſe the *milk* is often perfectly watery, and the child is thrown into an atrophy by it. The remedies for this are, change of diet, and a purging of the primæ viæ by ſome gentle cathartic, and afterwards a ſtrengthening of them by bitters, and ſtomachic medicines. Sometimes alſo it is neceſſary to evacuate the ſerous humours by the common phlegmagogues, ſuch as jalap in proper doſes, mixed with a little powdered ginger, which is an excellent corrective for it.

The *milk* is ſometimes ſalt to the taſte, and ſometimes of a bilious yellow colour; and theſe diſtemperatures of it uſually throw the child into colics, diarrhœas, vomitings, cutaneous eruptions, with ſcabs, and ſometimes abſolute ulcerations, and ſometimes into fevers. In this caſe the nurſe or parent is to take the abſorbents and nitrous medicines, with intermediate purges; thus, powders of crabs-eyes, oyſter-ſhells, and purified nitre, with ſmall doſes of rhubarb occaſionally taken, often perfect a cure: but during the courſe of taking theſe remedies, and for ſome time afterwards, the diet muſt be under ſome regulation, particularly ſalt foods are to be avoided; and all acids, aromatics, and ſtrong liquors, either wholly let alone, or taken very ſparingly. The perſon muſt alſo carefully avoid all violent paſſions of the mind, as anger, fear, and the like; and abſtain from all violent emotions of the body.

A contrary extreme to the thinneſs and watery appearance of the *milk* before deſcribed, is, a *morbid thickneſs of it*. This is principally troubleſome and dangerous to the parent, as it is apt to bring on tumors and nodes in the breaſt. The method of treatment in this caſe, is to give gentle alexipharmics for ſome days, then the gentle laxative medicines in ſmall doſes, and finally to allow a moderate uſe of wine.

MILK, *ſtagnations of the*. Theſe are very frequent in lyings-in, and are to be diſcuſſed by the ſame method as was before ordered for the ſending it back, in caſes where perſons do not chooſe to give ſuck; and, to the things there directed, may be added, the internal uſe of ſperma-ceti, and of calcined mountain-cryſtals, in powder; and externally, cataplaſms of ſperma-ceti with ſome volatile urinous ſalt, and the gentle compreſſions of the breaſts by wearing ſtreight cloths about the part.

Nodes of the breaſts often ariſe from the abundance and the mucous nature of the *milk*. They are to be diſcuſſed by plaiſters of ſperma-ceti, with aniſe, parſley, and coriander ſeeds; and by gently rubbing with a ſoft fleſh-brush, as alſo by wearing ſome animal's ſkin that has a thick fur on it, which at once ſerves the double office of warmth and a gentle friction. See TUMORS *of the Breaſts*.

Abſceſſes of the breaſts very often happen alſo from the ſame cauſes; and theſe when there appear no hopes of diſcuſſing them are always to be brought to ſuppuration as quick as poſſible. A maturating plaiſter is to be laid on the parts that are to be broke, and the other parts are to be rubbed with ſpirit of wine and camphor, and laſtly infuſed in it. When the matter in the abſceſs is ripe, if the ſkin do not burſt of *itſelf* it is to be immediately opened with a lancet; after this a plaiſter of equal parts of diachylon ſimplex and that with the gums, with a little camphor mixed in it, is to be applied; and afterwards digeſtives are to be wholly avoided, and no dreſſings but balſamics allowed. The liquor of myrrh, or a mixture of eſſence of myrrh, and amber, and ſpirits of turpentine, make an admirable dreſſing; and internally, gentle purges are to be given, and the milder diuretics with the nitrous and ſaline medicines.

Cracks and fiſſures of the nipples are another very troubleſome complaint with thoſe who give ſuck. The beſt applications to theſe, are the oil of eggs with the liquamen of the buds of the poplar, oil of wax, linſeed oil ſhook together with the whites and yolks of eggs, a liniment made of marygold flowers and freſh butter, an ointment of liquorice and the liquor produced from the flowers of mullein and marygolds, heated together in an oven; or they may be anointed with a mixture of oil and bees wax; or a little powdered gum arabic may be ſprinkled on them. Hungary water applied to the nipples has ſometimes a good effect. The ſucking out the *milk*, by means of a glaſs-pipe, is very neceſſary during the continuance of this complaint; but the beſt method of preventing it, is the applying white wax to the nipples for ſome time before, as well as after the time of the labour. If the complaint ſhould prove obſtinate, a cooling purge may be given, which generally removes it.

The ſmallneſs of the nipples is a trouble to many nurſes; when the complaint is only owing to their lying-in, the breaſts are to be forced out by the ſucking of a robuſt child of ſix or more months old, by the application of the common glaſs-pipe, firſt made warm, and by the ſucking of a grown perſon, experienced in ſuch caſes: all natural accidents of this kind may be cured by this means; but often the nipples have been ſo forced in by the ſtays, at the very time of their growth in young girls, and this force continued ſo long, that no art is able to recall them to their natural ſtate, or make them fit for an infant to ſuck from.

The miſchiefs that ſometimes attend perſons who have given ſuck, in the weaning of children, or on the death of a child, and the *milk* being left undrawn out, are to be avoided, by letting ſome other child ſuck a little at a time, and that leſs and leſs every day, and by drawing afterwards a little every day with a pipe.

It is very common among nurſes to be extremely ſcrupulous about diet, and to require the niceſt foods for the creating good *milk*; but it is evident, that though ſome care is neceſſary to this purpoſe, yet it is not this; for the poorer people, who live on the coarſeſt food, often have the richeſt *milk*. The whole neceſſary caution ſeems to conſiſt in avoiding exceſs, and feeding as much as poſſible on ſimple foods, without too many vegetables, and not to lead too ſedentary a life.

Things hard of digeſtion are to be abſtained from, as alſo acids; too fat meats, and all flatulent things, and the acrid and aromatic things are to be very carefully meddled with; ſince, though they do not affect the mother, they ſeldom fail to bring diſtempers upon the child. There is no better drink for thoſe who give ſuck than malt-liquors, when they are well ſettled and clear. Stronger

things, even wine in those who are habituated to it; though it do not hurt them, are to be refrained from, since they subject the child to convulsions and many other disorders.

Over large draughts of cold liquors, and the exposing the breasts too much to the cold, are often the causes of very great disorders both in the mother and the child. Gentle exercise, and motion of the body in general, is highly serviceable to nurses; as is also that of the breasts in particular, by gently shaking and pressing them for throwing off the aqueous part of the *milk*, and filling the lactiferous ducts more freely and copiously than would otherwise be done. The improper methods of dress in some places, and squeezing the girls into slenderness by strait stays, often occasion the lactiferous ducts to be so contracted, and the nipple so depressed, that no art can afterwards bring the person to be properly qualified for suckling a child. Junker's Conf. Med. p. 732, *seq.*

Violent passions of the mind are extremely injurious to those who give suck. It is very common to see nodes and abscesses of the breasts brought on by these alone, and erysipelatous inflammations are as frequent in persons of other habits, from the same causes. The child also is often thrown into diarrhœas, by these means; and in general, it is a very necessary rule to squeeze and shake the breasts to discharge the *milk* after a great fright, or a violent fit of passion, before the child is suffered to suck. If the menses appear at the time of giving suck, the child is usually greatly injured by the alteration the *milk* suffers.

When women are newly laid in, if the breasts become turgid, and there is danger of the *milk*'s coagulating in them, the child if it be strong, should be immediately put to suck; but if otherwise, the breasts are to be gently shaken and pressed to discharge the redundancy, or another child, or grown person, put to suck them.

MILK, *extract of*, a sweet dry extract of cow's milk made by evaporation.

Fred. Hoffman recommends this extract boiled with pure water to the quantity of what is exhaled of the *milk*, as an excellent drink in many disorders, where *milk* itself is not proper.

Milk is often thought improper with purgatives, and it certainly does render some persons costive; but this does not hold generally, nor perhaps for a long time, even in those whom it may so affect at first. Hoffman recommends an ounce of *manna* dissolved in a pint of *milk* as a good laxative.

MILK *vetch*. See ASTRAGALUS.

MILK *vetch, baſtard*. See VETCH.

MILK-*wood*. See TRUMPET-*flower*.

MILK-*wort, polygala*, in *Botany*, a genus of the *diadelphia octandria* claſs. Its characters are these: the flower has a small permanent empalement, and is shaped like those of the butterfly kind; the number of petals indeterminate; the wings are large, plain, and extend beyond the other petals; the ſtandard is rubulous, ſhort, and reflexed at the brim, where it is bifid; the keel is concave, compreſſed, and bellied toward the top; it has eight ſtamina in two bodies, included in the keel, terminated by ſingle ſummits; and an oblong germen ſupporting an erect ſtyle, terminated by a thick bifid *ſtigma*; the germen becomes a heart-ſhaped capſule, having two cells, each containing one ſeed. Miller enumerates only ſeven ſpecies, ſome of them natives of Europe, others of America; but Linnæus reckons twenty-ſix ſpecies.

The common *milk-wort* is frequently found in dry meadows, and flowers in July; the herb itſelf is only uſed; its bitter taſte proves it to be of a hot and drying quality. The leaves, boiled in wine, purge bile by ſtool. The roots have been found to produce the ſame effects in pleuriſies, as the SENEKA in a lower degree.

MILK-WORT, or *worm-wort*. See SURGE.

MILK-WORT, *ſea*. See GLAUX.

MILKY *geniſta*. See GROTTO.

MILKY *way, via lactea*, or *galaxy*. See GALAXY.

MILL, in propriety, denotes a machine for grinding corn, &c. but, in a more general ſignification, is applied to all machines whoſe action depends on a circular motion.

Of theſe there are ſeveral kinds, according to the various methods of applying the moving power; as water-*mills*, wind-*mills*, *mills* worked by horſes, &c.

Few people are ignorant, that corn is ground by two *mill*-ſtones, placed one above the other, without touching. The lower *mill*-ſtone is immoveable, but the upper one turns upon a ſpindle. The oppoſite ſurfaces of the two ſtones, which act to grind the corn, are not plane or flat; but the upper one is hollow, and the under one ſwells up; each of them being of a conic figure, whoſe *axis* indeed is very ſhort, in proportion to the diameter of its baſe: for the upper one, being ſix feet in diameter, is hollowed but about one inch at its centre; and the lower one riſes but about three-fourths of an inch. Theſe two *mill*-ſtones come nearer and nearer towards their circumference, whereby the corn that falls from the hopper has room to inſinuate between them as far as two-thirds of the radius, which is the place where it begins to be ground, and where it makes the greateſt reſiſtance that it is capable of; the ſpace between the two ſtones being in that place about but two-thirds or three-fourths of a thickneſs of a grain of corn. But as the millers have a liberty of raiſing or ſinking the upper ſtone a little, to gain proportion its diſtance from the lower one, according as they would have the flour finer or coarſer.

In order to cut and grind the corn, both the upper and under *mill*-ſtones have channels or furrows cut in them, proceeding obliquely from the centre towards the circumference. And theſe furrows are each cut perpendicularly on one ſide, and obliquely on the other, into the ſtone; which gives each furrow a ſharp edge, and in the two ſtones, they come, as it were, againſt one another, like the edges of a pair of ſciſſars; and ſo cut the corn to make it grind the eaſier, when it falls upon the places between the furrows. Theſe are cut the ſame way in both ſtones when they lie upon their backs, which makes them run croſs-ways to each other, when the upper ſtone is inverted by turning its furrowed ſurface towards that of the lower. For if the furrows of both ſtones lay the ſame way, a great deal of the corn would be drove onward in the lower furrows, and ſo come out from between the ſtones without ever being cut. When the furrows become blunt and ſhallow by wearing, the running ſtone muſt be taken up, and both ſtones new dreſt with a chiſſel and hammer. But by this repeated operation, their thickneſſes, and conſequently their weights diminiſh; and it is obſerved, that when they come to have but three quarters, or half of the thickneſs which they had when new, they produce but three quarters or half the flour which they yielded at the beginning.

The circular motion of the upper *mill*-ſtone brings the corn out of the hopper by jerks, and cauſes it to recede from the centre towards the circumference, where being quite reduced to flour, it is thrown out of the *mill*, by the centrifugal force of the ſtone, through a hole provided on purpoſe.

The diameter of common *mill*-ſtones, according to Dr. Deſaguliers, is from five to ſeven feet, and their thickneſs, twelve, fifteen, or eighteen inches: they laſt thirty-five or forty years; and when they have been long uſed, ſo that their thickneſs is conſiderably diminiſhed, they are cut anew, to give their ſurface a contrary figure to what they had before: ſo that the upper *mill*-ſtone is made the lower.

In water-*mills*, the momentum of the water is the moving power, and the attrition of the two ſtones in grinding, is the force to be overcome. Of theſe there are two kinds, viz. thoſe where the force of the water is applied above the wheel, and thoſe where it is applied below the wheel; the former being called over-ſhot, and the latter under-ſhot *mills*: and to theſe we may add a breaſt-*mill*, where the water ſtrikes againſt the middle of the wheel.

In a common breaſt *mill*, where the fall of water may be about ten feet, AA, *Tab.* V. *Mechanics, fig.* 65, N° 2. is the great wheel, which is generally about ſeventeen or eighteen feet diameter, from *a* the outermoſt edge of any float board, to *b* that of its oppoſite float. To this wheel the water is conveyed through a channel, and falling upon the wheel, turns it round. On the axis BB, of this wheel, and within the *mill*-houſe, is a wheel D, about eight or nine feet diameter, having ſixty-one cogs, which turn a trundle, E, containing ten upright ſtaves or rounds; and when this is the number of cogs and rounds, the trundle will make 6 ½ revolutions for one revolution of the wheel. The reaſon of adding an odd cog, called the hunting cog, to the wheel, is this; that, as every cog comes to the trundle, it may take the next ſtaff or round behind the one which it took in the former revolution, and thus it will wear all the parts of the cogs and rounds which work upon one another equally, and to equal diſtances from one another in a little time; and make a true uniform motion throughout the whole work. The trundle is fixed upon an iron axis called the ſpindle, the lower end of which turns in a braſs foot, *fig.* [illegible] in the horizontal beam ST, called the bridge-tree, and the upper part of the ſpindle turns in a wooden [illegible] fixed into the lower *mill*-ſtone, which lies upon beams in the floor YY. The top part of the ſpindle above the [illegible] is ſquare, and goes into a ſquare hole in a ſtrong iron croſs, *abcd*, *fig.* 66. N° 2. called the rynd; under which, and cloſe to the buſh, is a round piece of thick leather upon the ſpindle, which it turns round at the ſame time as it does the rynd. The rynd is ſet into grooves in the under ſurface of the running *mill*-ſtone G, *fig.* 65. N° 2. and ſo turns it round in the ſame time that the trundle E is turned round by the cog-wheel D. This *mill*-ſtone has a large hole quite through its middle, called the eye of the ſtone, through which the middle part of the rynd and upper end of the ſpindle may be ſeen; whilſt

whilſt the four ends of the rynd lie hid below the ſtone in their grooves.

The end T of the bridge-tree T S (which ſupports the upper *mill*-ſtone G upon the ſpindle) is fixed into a hole in the wall; and the end S is let into a beam Q R called the brayer, whoſe end R remains fixt in a mortiſe: and its other end Q hangs by a ſtrong iron rod P, which goes through the floor Y Y, and has a ſcrew-nut on its top at O; by the turning of which nut, the end Q of the brayer is raiſed or depreſſed at pleaſure; and conſequently the bridge-tree T S and upper *mill*-ſtone. By this means, the upper *mill*-ſtone may be ſet as cloſe to the under one, or raiſed as high from it, as the miller pleaſes. The nearer the *mill*-ſtones are to one another, the finer they grind the corn; and the more remote from one another, the coarſer.

The upper *mill*-ſtone G is incloſed in a round box H, which does not touch it any where; and is about an inch diſtant from its edge all around. On the top of this box ſtands a frame for holding the hopper *k k*, to which is hung the ſhoe I, by two lines faſtened to the hind-part of it, fixed upon hooks in the hopper, and by one end of the crook-ſtring K faſtened to the fore-part of it at *i*; the other end being twiſted round the pin L. As the pin is turned one way, the ſtring draws up the ſhoe cloſer to the hopper, and ſo leſſens the aperture between them; and as the pin is turned the other way, it lets down the ſhoe, and enlarges the aperture.

If the ſhoe be drawn up quite to the hopper, no corn can fall from the hopper into the *mill*; if it be let a little down, ſome will fall: and the quantity will be more or leſs, according as the ſhoe is more or leſs let down. For the hopper is open at bottom, and there is a hole in the bottom of the ſhoe, not directly under the bottom of the hopper, but forwarder towards the end *i*, over the middle of the eye of the *mill*-ſtone.

There is a ſquare hole in the top of the ſpindle, in which is put the feeder *e* (*fig.* 66. N° 2.) this feeder (as the ſpindle turns round) jogs the ſhoe three times in each revolution, and ſo cauſes the corn to run conſtantly down from the hopper, through the ſhoe, into the eye of the *mill*-ſtone, where it falls upon the top of the rynd, and is, by the motion of the rynd and the leather under it, thrown below the upper ſtone, and ground between it and the lower one. The violent motion of the ſtone creates a centrifugal force in the corn going round with it, by which means it gets farther and farther from the centre, as in a ſpiral, in every revolution, until it be thrown quite out; and, being then ground, it falls through a ſpout M, called the *mill*-eye, into the trough N. When the *mill* is fed too faſt, the corn bears up the ſtone, and is ground too coarſe; and beſides, it clogs the *mill* ſo as to make it go too ſlow. When the *mill* is too ſlowly fed, it goes too faſt, and the ſtones by their attrition are apt to ſtrike fire againſt one another. Both which inconveniencies are avoided by turning the pin L backwards or forwards, which draws up or lets down the ſhoe; and ſo regulates the feeding as the miller ſees convenient.

Sometimes, where there is a ſufficient quantity of water, the cog-wheel in *fig.* 65. turns a large trundle, on whoſe axis is fixed a horizontal wheel, with cogs all around its edge, turning two trundles at the ſame time; whoſe axes or ſpindles turn two *mill*-ſtones. When there is not work for them both, either may be made to lie quiet, by taking out one of the ſtaves of its trundle, and turning the vacant place towards the horizontal cog-wheel. And there may be a wheel fixed on the upper end of the great upright axle of this wheel for turning a couple of bolting-*mills*; and other work for drawing up the ſacks, fanning and cleaning the corn, ſharpening of tools, &c.

As the water acts upon an over-ſhot *mill* both by impulſe and weight, ſo does it likewiſe upon a breaſt-*mill*, or that where the water comes upon the breaſt or middle-part of the wheel: and here, though the weight of the water is not ſo great as in the overſhot *mill*, being contained in the buckets of the lower quarter only; yet the impulſe of the water is much greater, the height of the water being increaſed nearly the ſemi-diameter of the great wheel, all other things being equal. If the height of the water remain the ſame, the aperture of the penſtock muſt be enlarged to nearly twice the area, that the force may be the ſame; ſo that to produce the ſame effect, twice as much water is neceſſary for a breaſt-*mill* as for an overſhot one, every thing elſe being the ſame.

Mr. Ferguſon obſerves, that where there is but a ſmall quantity of water, and a fall great enough for the wheel to lie under it, the bucket or overſhot wheel is always uſed. But where there is a large body of water, with a little fall, the breaſt or ſtoat-board wheel muſt take place. As to the under-ſhot *mill*, it is evident there can be only the impulſe from the water; and therefore, the height of the water remaining the ſame, there muſt be a larger aperture of the penſtock for the diſcharge of a greater quantity of water in the ſame time, in order to produce the ſame effect as the over-ſhot or breaſt-*mill*; whence a greater expence of water will be made here than in any other *mill*, and can only be ſupplied for a conſiderable time by a river; and where this can be had, the under-ſhot is the eaſieſt, cheapeſt, and moſt ſimple ſtructure, a *mill* is capable of.

Dr. Deſaguliers, having had occaſion to examine many under-ſhot and over-ſhot *mills*, generally found that a well made over-ſhot *mill*, ground as much corn, in the ſame time, as an under-ſhot *mill*, with ten times leſs water; ſuppoſing the fall of water at the over-ſhot, to be twenty-feet, and at the under-ſhot to be about ſix or ſeven feet: and he generally obſerved, that the wheel of the overſhot-*mill* was of fifteen or ſixteen feet diameter, with a head of water of four or five feet, to drive the water into the buckets with ſome momentum.

Mr. Ferguſon has given the following directions how to conſtruct water-*mills*, ſo as to be in the greateſt degree of perfection; and alſo a Table calculated from his rules, for the eaſe of thoſe mill-wrights who either cannot calculate or do not like to take the trouble.

When the float-boards of the water-wheel move with a third part of the velocity of the water that acts upon them, the water has the greateſt power to turn the *mill*: and when the *mill*-ſtone makes about ſixty revolutions in a minute, it is found to do its work the beſt. For, when it makes but about forty or fifty, it grinds too ſlowly; and when it makes more than ſeventy, it heats the meal too much, and cuts the bran ſo ſmall that a great part thereof mixes with the meal, and cannot be ſeparated therefrom by ſifting or bolting. Conſequently, the utmoſt perfection of *mill*-work lies in making the train ſo, as that the *mill*-ſtone ſhall make about ſixty turns in a minute when the water-wheel moves with a third part of the velocity of the water. To have it ſo, obſerve the following rules:

1. Meaſure the perpendicular height of the fall of water, in feet, above the middle of the aperture, where it is let out to act by impulſe againſt the float-boards on the loweſt ſide of the under-ſhot wheel.

2. Multiply this conſtant number 64.2882, by the height of the fall in feet, and extract the ſquare root of the product, which ſhall be the velocity of the water at the bottom of the fall; or the number of feet the water moves *per* ſecond.

3. Divide the velocity of the water by 3; and the quotient ſhall be the velocity of the floats of the wheel in feet *per* ſecond.

4. Divide the circumference of the wheel in feet, by the velocity of its floats; and the quotient ſhall be the number of ſeconds in one turn or revolution of the great water wheel, on whoſe axis the cog wheel that turns the trundle is fixed.

5. Divide 60 by the number of ſeconds in a turn of the water-wheel or cog-wheel; and the quotient ſhall be the number of turns of either of theſe wheels in a minute.

6. By this number of turns divide 60 (the number of turns the *mill*-ſtone ought to have in a minute) and the quotient ſhall be the number of turns the *mill*-ſtone ought to have for one turn of the water or cog-wheel. Then,

7. As the required number of turns of the *mill*-ſtone in a minute is to the number of turns of the cog-wheel in a minute, ſo muſt the number of cogs in the wheel be to the number of ſtaves in the trundle on the axis of the *mill*-ſtone, in the neareſt whole number that can be found.

By theſe rules the following table is calculated; to which, the diameter of the water-wheel is ſuppoſed to be 18 feet, (and conſequently its circumference 56.5 feet) and the diameter of the *mill*-ſtone to be 5 feet.

Ferguſon's height of the fall of water in feet.	Velocity of the water per ſecond.	Velocity of the floats.	Seconds in which the wheel turns round.	Number of cogs in the wheel.	Number of turns of the wheel in a minute.	Number of the mill-ſtone turns for one of the wheel.	Number of turns by the thirſh-cloſe cogs ſpindle.	Number of ſtaves in the trundle.

Example. Suppose an under-shot *mill* is to be built where the perpendicular height of the fall of water is 9 feet: it is required to find how many cogs must be in the wheel, and how many staves in the trundle, to make the *mill*-stone go about 60 times round in a minute, while the water wheel-floats move with a third part of the velocity with which the water spouts against them from the aperture at the bottom of the fall.

Find 9 (the height of the fall) in the first column of the table; then, against that number, in the sixth column, is 70, for the number of cogs in the wheel, and 10 for the number of staves in the trundle: and by these numbers, we find in the eighth column that the *mill*-stone will make $59\frac{1}{2}$ turns in a minute, which is within half a turn of 60, and near enough for the purpose; so it is not absolutely requisite that there should be just 60 without any fraction: and throughout the whole table the number of turns is not quite one more or less than 60.

The diameter of the wheel being eighteen feet, and the fall of water 9 feet, the second column shews the velocity of the water, at the bottom of the fall, to be 24,25 feet per second; the third column, the velocity of the float-boards of the wheel to be $8\frac{1}{12}$ feet per second; the fourth column shews that the wheel will make $8\frac{1}{12}$ turns in a minute; and the sixth column shews, that for the *mill*-stone to make exactly 60 turns in a minute, it ought to make 7,82 (or seven turns and five hundred parts of a turn) for one turn of the wheel.

Dr. Barker has invented a water-*mill*, that has neither wheel nor trundle: this is represented in *fig.* 72. in which A is a pipe or channel that brings water to the upright tube B. The water runs down the tube, and thence into the horizontal trunk C, and runs out through holes at *d* and *e* near the ends of the trunk on the contrary sides thereof.

The upright spindle D is fixt in the bottom of the trunk, and screwed to it below by the nut *g*; and is fixt into the trunk by two cross bars at *f*: so that, if the tube B and trunk C be turned round, the spindle D will be turned also.

The top of the spindle goes square into the rynd of the upper *mill*-stone H, as in common *mills*; and as the trunk, tube, and spindle turn round, the *mill*-stone is turned round thereby. The lower, or quiescent *mill*-stone is represented by I; and K is the floor on which it rests, and wherein is the hole L for letting the meal run through, and fall down into a trough which may be about M. The hoop or case that goes round the *mill*-stone rests on the floor K, and supports the hopper, in the common way. The lower end of the spindle turns in a hole in the bridge-tree G F, which supports the *mill*-stone, tube, spindle, and trunk. This tree is moveable on a pin at *b*, and its other end is supported by an iron-rod N fixt into it, the top of the rod going through the fixt bracket O, and having a screw-nut *a* upon it, above the bracket. By turning this nut forward or backward, the *mill*-stone is raised or lowered at pleasure.

Whilst the tube B is kept full of water from the pipe A, and the water continues to run out from the ends of the trunk; the upper *mill*-stone H, together with the trunk, tube, and spindle, turns round. But if the holes in the trunk were stopt, no motion would ensue; even though the tube and trunk were full of water. For,

If there were no hole in the trunk, the pressure of the water would be equal against all parts of its sides within. But, when the water has free egress through the holes, its pressure there is entirely removed: and the pressure against the parts of the sides which are opposite to the holes, turns the machine. See Desaguliers's Exp. Phil. vol. ii. p. 417, &c. p. 431, &c. p. 450, &c. Ferguson's Mechanics, p. 45. &c. 420. ed. and supp. p. 10. * See also, on this subject, an elaborate paper of Mr. Smeaton, containing an account of a number of experiments, in order to estimate the natural powers of water and wind to turn *mills* in the Phil. Trans. vol. li. art. 18. p. 100, &c.

Persons riotously assembling and destroying, or maliciously burning, any wind-saw-*mill*, wind-*mill*, or water-*mill*, &c. shall be guilty of felony, without benefit of clergy, by 9 Geo. III. c. 29.

MILLS, *wind*, are, with respect to their working parts, little different from those of water-*mills*; but they are turned by the force of wind gathered in their sails.

Of these, some are called *vertical*, others *horizontal*, according to the position of the sails; or, rather, according to the direction of their motion, with regard to the horizon.

For the best form of horizontal sails, and also for determining the position of the axis of *wind-mills*, see WIND-*mill* and MECHANICS.

MILLS, *portative* or *hand*, are those kept in motion by the hand; or else whose *mill*-stones are turned, or pistons driven, by the force of horses, or other beasts. Thus, if the cog-wheel D, *fig.* 65, N° 2, be made about eighteen inches diameter, with thirty cogs, the trundle as small in proportion, with ten staves, and the *mill*-stones be each about two feet in diameter, and the whole work be put into a strong frame of wood, as represented in the figure, the engine will be a *hand-mill* for grinding corn or malt in private families. And then, it may be turned by a winch instead of the wheel A A; the *mill*-stone making three revolutions for every one of the winch. If a heavy fly be put upon the axle B, near the winch, it will assist greatly in regulating the motion.

If the cog-wheel that turns the trundle or trundles of a *mill* be placed horizontally, horizontal levers may be fixed into its vertical axis, and horses applied to these for turning the *mill*: which is often done where water cannot be had for that purpose.

The use of *mills* and *mill*-stones, according to Pausanias, was first invented by Myla, son of Melegus, first king of Sparta; though Pliny attributes the invention of every thing belonging to bread and baking, to Ceres: Polydore Virgil was not able to discover the author of so useful a machine. It is doubted, whether or no water-*mills* were known to the Romans, there being no mention made, in the Digest, but of *mills* turned by slaves and asses. Salmasius, however, and Gothofred, will not allow water-*mills* to have been unknown to the ancient Romans, though they were not in ordinary use. Wind-*mills* are of much more modern invention: the first model of these was brought from Asia into Europe, in the time of the holy wars.

MILL is also used for any machine, which, being moved by some external force, serves to give a violent impression on things applied to it.

Mills in this sense, are machines of vast use in the manufactures, arts, and trades; for the making and preparing divers kinds of merchandizes. The principal are those which follow.

MILLS, *forge*, turned by water, serve to raise and let fall one or more huge hammers, to beat and form the iron into bars, anchors, and other massive works.

MILL, *fulling*, is a *water-mill* which raises and beats down large wooden pistons in proper vessels called *pools*, or *troughs*; in order to full, scour, and cleanse woollen stuffs.

MILL, *gunpowder*, is that used to pound and beat together the ingredients whereof gunpowder is composed.

This is done, in a kind of iron or brass mortar, by means of iron pestles wrought by a wheel without-side the *mill*, turned by the water falling on it.

MILLS, *leather*, are used to scour, and prepare with oil, the skins of stags, buffaloes, elks, bullocks, &c. to make what they call *buff-leather*, for the use of the soldiery.

This is effected by means of several large pistons, rising and falling on the skins, in large wooden troughs, by means of a wheel without-side, turned by the force of water.

MILLS, *linen*, do not differ much from *fulling-mills*. Their use is, to scour linens, after their having been first cleansed when taken out of the lixivium, or ley. Some of these go by water, and the generality by horses.

MILLS, *oil*, whether turned by men, water, hand, or horse, serve to bruise or break the nuts, olives, and other fruits and grains, whose juice is to be drawn, by expression, to make oil.

MILL, *paper*, a *water-mill* furnished with several large hammers, which beat or pound the rags or cloth in a kind of wooden troughs; and thus, by reducing them to little pieces, turn them into a kind of pulp, by means of water conveyed into the troughs by a pipe for that purpose.

MILL, *sawing*, is a *water-mill*, serving to saw several planks or boards, at the same time.

These are frequent in France, especially in Dauphiné. They were lately prohibited in England, where they were begun to be introduced, from a view to the ruin of the sawyers, which must have ensued.

There are also *Silk*-MILLS, for spinning, throwing, and twisting silks; which are large round machines in form of turrets, five or six feet high, and six yards in diameter; which, being turned, either by the force of water, or that of men, work at the same time an infinity of bobbins fastened thereto, whereon the silk had been wound to be here spun and twisted.

There are abundance of *mills* of this kind in France, especially about Lyons and Tours, some of which are so disposed, as that three of them will go at the same time, and by the same wheel wrought by water, or by strength of hand. That in the Hôpital de la Charité at Lyons, is wonderful, a single man working no less than forty-eight of these *mills*. See SILK, and WINDING *of Silk*.

MILL, *stamping*. See STAMPING.

MILL, *sugar*, is a machine that ſerves to bruiſe the ſugar-canes, and expreſs the liquor or juice contained therein. The *ſugar-mills* are very curious contrivances. Of theſe there are four kinds, being turned either by water, wind, men, or horſes.

Thoſe turned by the hand were firſt in uſe; but they are now laid aſide, as being an intolerable hardſhip on the poor negroes, who were doomed thereto, beſides the ſlowneſs of their progreſs.

Wind-mills are the moſt modern: but they are yet ſomewhat rare, excepting in St. Chriſtopher's and Barbadoes, and among the Portugueſe. Theſe make good diſpatch, but have this inconvenience, that they are not eaſily ſtopped; which proves frequently fatal to the negroes who feed them.

MILLS, *tan* or *bark*, wrought by water or horſes, ſerve to cut certain barks into a coarſer ſort of powder, proper for the tanning of hides, &c.

MILLS *for ſword-blades* are likewiſe moved by water. They are frequent at Vienne in Dauphiné. By working heavy hammers they forge thoſe excellent ſword-blades, called *blades of Vienne*.

The uſes and operations of theſe ſeveral mills, more at large, ſee under PAPER, FULLING, SUGARS, &c.

MILL, in *Coinage*, is a machine uſed to prepare the lamin\æ, or plates of metal, and to give them proper thickneſs, hardneſs, and conſiſtence, before they be ſtruck, or ſtamped.

This machine has not been long known among us; but is of ſome ſtanding in Germany. It conſiſts of ſeveral wheels dented like thoſe of clocks, &c. which move two cylinders of ſteel, between which the metal is paſſed to be brought to its proper thickneſs. It was firſt turned with water, ſince with horſes. See COINAGE.

MILL, among *Gold Wire-Drawers*, is a little machine conſiſting of two cylinders of ſteel, ſerving to flatten the gold or ſilver wire, and reduce it into lamin\æ, or plates. See GOLD WIRE.

They have alſo *mills* to wind the gold wire or thread on the ſilk: theſe are compoſed of ſeveral rows of bobbins all turned at the ſame time.

MILL-*dams*. A very firm way of making theſe in a quick or running ſand, which is uſually found a very troubleſome circumſtance in the making them, is by laying the foundation with unſlacked lime; which, by ſlacking among the ſand, runs together into a hard ſtone, which gives a very firm and ſure foundation. Plot's Staffordſhire, p. 336.

MILL-*pool*, a ſtock or pond of water, by the force of which the motion of a *water-mill* is effected.

The dam of a *mill-pool* is raiſed much in the ſame manner as directed for FISH-PONDS.

MILL-*ſtones*. The *mill-ſtones* which we find preſerved from ancient times, are all ſmall, and very different from thoſe in uſe at preſent. Thoreſby mentions two or three ſuch found in England, among other Roman antiquities, which were but twenty inches broad; and there is great reaſon to believe that the Romans, as well as the Egyptians of old, and the ancient Jews, did not employ horſes, or wind, or water, as we do, to turn their *mills*, but made their ſlaves and captives of war do this laborious work; they were in this ſervice placed behind theſe *mill-ſtones*, and puſhed them on with all their force.—Sampſon, when a priſoner to the Philiſtines, was treated no better, but was condemned to the *mill-ſtone* in his priſon. The runner or looſe *mill-ſtone*, in this ſort of grinding, was uſually very heavy for its ſize, being as thick as broad. This is the *mill-ſtone* which it is expreſsly prohibited in Scripture to take in pledge, as lying looſe it was more eaſily removed. The Talmudiſts have a ſtory, that the Chaldæans made the young men of the captivity carry *mill-ſtones* with them to Babylon, where there ſeems to have been a ſcarcity at that time; and hence, probably, their paraphraſe renders the text "have "borne the *mills*, or *mill-ſtones*;" which might thus be true in a literal ſenſe. They have alſo a proverbial expreſſion of a man with a *mill-ſtone* about his neck; which they uſe to expreſs a man under the ſevereſt weight of affliction. This alſo plainly refers to this ſmall ſort of ſtones.

MILLAINS, according to Mr. Wingate, are the third ſubdiviſion of the primes in Gunter's line; and expreſs the thouſandth parts of ſuch primes.

MILLEFOLIUM, in *Botany*. See YARROW.

MILLEMORBIA, in *Botany*, a name given by ſome authors to the ſcrophularia, or figwort, from its ſuppoſed virtues in many diſeaſes.

MILLENARII, MILLENARIANS, in *Eccleſiaſtical Hiſtory*, a ſect among Chriſtians, chiefly in the primitive church; who hold that Jeſus Chriſt is to come again, and reign on earth for the ſpace of a thouſand years; during which time, the faithful are to enjoy all manner of temporal bleſſings; and at the expiration of this term, the day of judgment is to take place.

The *Millenarii* are alſo called *Chiliaſti*, *Chiliaſtæ*, from the Greek χιλιας, *mille*, *a thouſand*.

This opinion of the *Millenarii* is very ancient, and may be traced back almoſt as far as the time of the apoſtles. It had its origin from a paſſage in the Apocalypſe too literally underſtood, wherein mention is made of Chriſt's reign on earth, &c.

The opinion of S. Papias, in the ſecond century, to whom Euſebius aſcribes the origin of this notion of a *millenium*, ſays Mr. Launoy, touching the new kingdom of Jeſus Chriſt on earth, after the reſurrection, was held for near three centuries, before it was charged as erroneous; as appears from eccleſiaſtical hiſtory. It was allowed of, and followed, under various interpretations, by ſeveral of the greateſt men among the primitive fathers, as Irenæus, Juſtin Martyr, Lactantius, Tertullian, &c. Towards the cloſe of the ſecond century, the credit of this opinion began to decline, principally through the influence and authority of Origen, who oppoſed it with the greateſt warmth, becauſe it was incompatible with ſome of his favourite ſentiments.

Nepos, an Egyptian biſhop, endeavoured to reſtore this opinion to its former credit, in a book written *againſt the Allegoriſts*, for ſo he called by way of contempt the adverſaries of the *millenarian* ſyſtem. But Dionyſius of Alexandria, a diſciple of Origen, ſtopped the growing progreſs of this doctrine by his private diſcourſe, and alſo by two learned and judicious diſſertations concerning the *divine promiſes*. Jerome is alſo ſaid to have oppoſed this *millenary* reign of Chriſt. The ancient *Millenarians* generally held, according to the account of the learned Dr. Whitby, that the temple, or the city of Jeruſalem, ſhould be rebuilt, and that the land of Judæa ſhould be the habitation of thoſe riſen ſaints, who were to reign on earth a thouſand years; that this reſurrection was not to be confined to the martyrs only, but that all the juſt were then to riſe and reign with Chriſt; and that this reign ſhould alſo extend to the juſt who were found alive at this firſt reſurrection; that Jeſus Chriſt ſhall then come down from heaven, and be ſeen on earth, and there reign with his ſervants; and that they ſhall then fare deliciouſly, and enjoy the richeſt wines and moſt delicious fruits, build houſes, plant vineyards and eat the fruits of them, and propagate their ſpecies. The *millennium*, according to this writer, is a glorious ſtate of the church, commencing after the fall of antichriſt; and the ſubſequence converſion of the Jews to the Chriſtian faith, in which it ſhall flouriſh in peace and plenty, in righteouſneſs and holineſs, and in a pious offspring, for a thouſand years, under the undiſturbed, though not perſonal government of Chriſt, over both Jews and Gentiles, which ſhall then be united in one church.

MILLENNIUM, compounded of *mille*, a *thouſand*, and *annus*, *a year*, a term literally ſignifying a *thouſand years*; chiefly uſed for the time of our Saviour's expected ſecond appearance, and reign on earth.

Mr. Whiſton, in ſeveral of his writings, has endeavoured to ſupport the notion of a *millennium*. According to his computation it was to have commenced about the year 1720.

MILLEPEDA, in *Conchyliology*, the name given by authors to a ſpecies of MUREX of the ſpider-ſhell kind, ſo called from the great number of prominences in the ſhape of points called feet in this ſeries of ſhells, which ariſe from its lip which is greatly extended. The body of the ſhell is full of bumps and tubercles, and the tail is long and crooked.

MILLEPEDES, in *Zoology*, well-known inſects, uſed on many occaſions in medicine. This inſect is otherwiſe called *aſellus*, being a ſpecies of ONISCUS, in Engliſh the *wood-louſe*. Mr. Ray deſcribes ſeven different ſpecies of this inſect, ſome of which we ſee every day, others are more rare. The blue kind, which rolls itſelf up into a ball, is the proper medicinal kind, though there is another ſort of a pale browniſh grey, ſmaller, flatter, and thinner than the former, and having the laſt diviſion of the body not annular but pointed, and a forked tail, which is of the ſame quality. They are found in cellars, and under ſtones and logs of wood in cold moiſt places.

Millepedes are ſo generally known, that moſt perſons ſeem to be maſters of their medicinal uſes, and take them in many caſes without any other direction. They are, by all experience, found to be very diuretic and abſterſive, which makes them not only frequent in preſcriptions for diſorders in the kidneys, but alſo in obſtructions of the viſcera, and particularly in the jaundice.

They abound with a nitrous ſalt, which they ſeem to derive from the earthy diet they live on. This is ſome-

what volatilized by its digeſtion and circulation in the inſect; as ſuch ſalt always is more or leſs, in proportion to the digeſtive powers of the animal, into whoſe blood it enters; yet not ſo much but that it is brackiſh and pungent upon the palate. This makes their deterſive qualities extend farther than the larger glands, and enables them to ſcour even the minuteſt paſſages, and keep the nerves clear from viſcidities, and ſuch things as would clog their ſprings; whence they are reckoned good in palſies, epilepſies, and all nervous diſtempers.

As they open and cleanſe away viſcoſities, and by their minuteneſs and aſperities cut their way through any obſtructions, they are good in ſtrumas, and all inveterate tumors or ulcers. Remarkable cures have been performed in each way by a long uſe of them. But it is much to be doubted, whether their virtues are ſo conſiderable as they are generally ſuppoſed to be, at leaſt when given in the cuſtomary doſes. They are beſt adminiſtered in ſubſtance, or bruiſed in white wine, the liquor being taken without ſettling.

The *millepedes præparatæ* of the ſhops are reduced to powder, either by incloſing them in a thin canvaſs cloth, and ſuſpending them over hot ſpirit of wine in a cloſe veſſel, till they are killed by the ſteam and rendered friable; or by incloſing them in a proper veſſel and drying them with a very gentle heat.

There are alſo ſeveral chemical preparations of *millepedes*, as ſpirit, volatile ſalt, oil, and wine of *millepedes*.

The college of Edinburgh directs two ounces of live *millepedes* to be ſlightly bruiſed, and digeſted for a night in a pint of Rheniſh wine, after which the liquor is to be preſſed through a ſtrainer.

Beſide theſe proper *aſelli*, there are ſome other ſpecies commonly called *pulices marini*, which ſeem greatly to approach to their nature. Theſe are, 1. the horned ſea *pulex*; its body is compoſed of twelve joints; it has ſeven pair of legs, and the hinder ones are longer than the others; the antennæ are a pair of very large horns, and at the baſe of theſe there ſtand two other very ſhort and ſlender ones; it has fins to ſwim with, and it is of a whitiſh colour, and very ſlender body. 2. The *pulex marinus* of Bellonius; this is of the ſhape of the common *aſelli*, but ſomewhat ſlenderer and rounder bodied, and its legs are much longer; its back is brown; its eyes are large and black, and the antennæ are articulated and have two ſmall ones growing from their roots; its body is pellucid, and it moves very ſwiftly in the water; the tail is compoſed of a large bundle of hairs. This is found in great plenty under ſtones, by the ſides of rivers, near the ſea. 3. The freſh-water *pulex*; this differs very little from the laſt ſpecies, but is ſingular in the places it inhabits, which are the banks and mud of hot ſprings, in which no other animal can live. Ray.

MILLEPORA, in *Natural Hiſtory*, a name by which Linnæus diſtinguiſhes that genus of *lithophytes*, of a hard ſtructure and full of holes, which are not ſtellate or radiated, and whoſe animal is the hydra, in which it differs from the MADREPORA, and comprehending fourteen different ſpecies.

In the *millepora*, the animal which forms and inhabits it occupies the ſubſtance: and it is obſerved, that the *milleporæ* grow upon one another: their little animals produce their ſpawn, which attaching itſelf either to the extremity of the body already formed, or underneath it, gives a different form to this production. Hence the various ſhapes of the *millepora*, which is compoſed of an infinite number of the cells of thoſe little inſects, which all together exhibit different figures, though every particular cellula has its eſſential form, and the ſame dimenſions, according to its own ſpecies. Philoſ. Tranſ. vol. xviii. p. 467.

MILLERIA, in *Botany*, a genus of the *ſyngeneſia polygamia neceſſaria* claſs: the characters of which are, that it hath no receptacle nor down; that the calyx has three valves; and that the radius is half the corolla. There are two ſpecies.

MILLERS-*thumb*, in *Ichthyology*, an Engliſh name for the fiſh called alſo the bull-head, and by authors the cottus; being the COTTUS *gobio* of Linnæus. It is common in all our clear brooks; lying generally at the bottom, and depoſiting its ſpawn in a hole formed by it in the gravel. It ſeldom exceeds three inches and a half in length; its head is large, broad, thin at its circumference, and on the middle part of the covers of the gills is a ſmall crooked ſpine, turning inwards; the eyes and teeth are ſmall; the body grows ſlender towards the tail; the colour is duſky mixed with yellow; and the belly whitiſh.

MILLET, *milium*, in *Botany*, a genus of the *triandria digynia* claſs. Its characters are theſe: it is of the corn or graſs tribe, with one flower in each chaff; the petal of the flower is bivalve, and ſmaller than the empalement; it hath three very ſhort hairy ſtamina, and a roundiſh germen with two hairy ſtyles; the germen turns to a roundiſh ſeed, covered by the petal of the flower. Miller reckons four, and Linnæus five ſpecies.

The firſt ſort grows naturally in India, but is now cultivated in many parts of Europe, as an eſculent grian. The ſecond grows naturally at la Vera Cruz.

The common *millet* was originally brought from the eaſtern countries, where it is ſtill greatly cultivated; from whence we are furniſhed annually with this grain, which is by many perſons greatly eſteemed for puddings, &c. This is ſeldom cultivated in England, but as a curioſity in ſmall gardens, or for poultry, as its ſeeds generally ripen well.

It muſt be ſown in the beginning of April, upon a warm dry ſoil, but not too thick, becauſe theſe plants, dividing into ſeveral branches, ſhould have much room. When they come up they ſhould be cleared from weeds; after which they will, in a ſhort time, get the better of them. In Auguſt they will ripen, when they muſt be cut down, and the ſeeds beat out, as is practiſed for other grain; but when it begins to ripen, if it be not protected from birds, they will ſoon devour it. Miller.

Millet is reckoned by Pliny the moſt fertile of all grain; one grain of it producing three Roman ſextaries.

Millet is cooling, drying, and binding, ſomewhat windy, and not eaſily digeſted; a ſtrong decoction of it with figs and raiſins, mixed with wine, and drank warm in bed, is a very good ſudorific, though it is ſeldom uſed.

Millet, by conſent of authors both ancient and modern, is refrigerating and drying; it is of bad juice, difficult of digeſtion, binds the belly, and generates flatulencies; it is however well known to be a very grateful food to many nations at preſent. In former times it ſerved to make bread, under a dearth of better corn, as we are aſſured by Dioſcorides, Pliny, Galen, and others of the ancients. Among the Italians, ſays C. Bauhine, loaves are made of *millet*, which are yellow, and eaten hot by many, not out of neceſſity, but for their ſweetneſs; but, when this bread is grown hard, it is quite black. Of the flour of *millet* and milk, the Italians make fine cakes, which muſt be eaten as ſoon as dreſſed, or elſe they become glutinous, and ungrateful to the taſte.

A pudding prepared of *millet*, boiled in milk with an addition of butter, and ſugar ſprinkled over it, is much in requeſt among the Germans at preſent; and theſe puddings have been long ago introduced into England, and are ſtill in faſhion.

The flour of *millet* was formerly uſed in fomentations, for the gripes, and for pains of the head and nerves; it was applied externally in bags, becauſe the uſe of it in cataplaſms was difficult, on account of its friability. If the membrane of the brain happens to be wounded, it is excellently conglutinated, ſays Archigenes, by infuſing thereon the juice of calaminth, and ſprinkling it with dry flour of *millet*. A decoction of *millet*, with figs and raiſins is called, by Heurnius, a noble ſudorific and diuretic. Or, take of a decoction of *millet*, boiled till it burſts, four ounces; white wine, two ounces: let the patient take it hot. Chefneau.

Millet is diuretic and aſtringent; the ſeeds are of extraordinary ſervice in diſeaſes of the lungs, and exulcerations of the kidneys: made into a cataplaſm, they are anodyne and reſolvent. Hiſt. Plant. adſcript. Boerhaave.

MILLET, *Indian*, *holcus*, in *Botany*, a genus of the *polygamia monoecia* claſs. The characters are, that it hath male and hermaphrodite flowers on the ſame plant; the male flowers are ſmall, and have a bivalve chaff; they have neither petals, nor any proper empalement, but have three hairy ſtamina, terminated by oblong ſummits; the hermaphrodite flowers are ſingle, in a thin bivalve chaff; they have three hairy ſtamina, terminated by oblong ſummits, with a roundiſh germen, ſupporting two hairy ſtyles, crowned with plumoſe ſummits; the germen becomes an oval ſingle ſeed, wrapped up in the chaff. There are ſeveral ſpecies of graſs that belong to this genus.

The African *millet* has been lately recommended by M. Tſchiffeli, of Switzerland, to the attention of the European farmers, as a very uſeful plant; becauſe it thrives in all ſorts of ſoils; it requires neither much dung nor great tillage; it is not ſubject to the depredations of birds, which are very fond of panic and common *millet*; it yields very large returns, and does not exhauſt the land in proportion to the largeneſs of the crops.

MILLIARE, or MILLIARIUM, among the Romans, *denoted a mile*, conſiſting of a thouſand paces, *mille paſſus*; whence the name.

In the Roman empire, the *milliaria*, in all the great roads, were marked with ſtones, or columns erected for that purpoſe; commencing from a columu in the heart of the city, called *milliare aureum*.

Thoſe

Thoſe columns were alſo hence denominated *milliary columns*.

MILLIARIA *robora*. See CONORS *equitata*.

MILLIARY *fevers*, *glands*, *herpes*, *terms*. See the ſeveral ſubſtantives.

MILLING, in the *Manufactories*, an operation called alſo FULLING.

MILLING, or *throwing of ſilk*, is the laſt preparation of ſilk before dyeing; ſerving to twiſt it, more or leſs, according to the work for which it is intended.

To prepare the ſilk for *milling*, they firſt put it in boiling water, incloſed between two linen cloths. The mill is a ſquare machine, compoſed of ſeveral pieces of wood, mortiſed in each other, ſo as to form a kind of large cage, in the centre whereof are two wheels placed parallel over each other, whoſe axis bears on two poſts. When the machine is ſimple, a ſingle man turns theſe wheels by means of a little cog in which they catch, and a large handle.

The wheels, put in motion by the handle, communicate their motion to eight windles, or reels, or even more, according to the largeneſs of the machine; on the ſlights or arms whereof the ſilk is wound from off two rows of bobbins placed on each ſide the machine, each row at the height of one of the two wheels in the centre. Theſe bobbins have their motion by means of leathern thongs, which bear on little cylinders of wood that ſupport them, and turn at length on the two wheels at the centre; ſo that the ſilk on each bobbin twiſts as it winds, and forms its ſeparate ſkein.

The ſmalleſt wheel moves two hundred of theſe bobbins, over which a ſingle perſon is ſufficient to inſpect, to put new bobbins or ſpools in lieu of thoſe diſcharged of their ſilk, and to knot the ends when they break. See WINDING *of ſilk*.

MILLION, in *Arithmetic*, the number of ten hundred thouſand; or a thouſand times a thouſand.

A *million of* GOLD, or *million of money*, is ſometimes underſtood of a *million* of pounds; and ſometimes of a *million* of crowns.

MILLION *bonds*. See BANK.

MILLMOTH, in *Natural Hiſtory*, the name of an inſect approaching to the nature of the beetle, but having no heath wings. It is common in the abodes of millers and bakers, and other perſons who deal in meal.

MILPHOSIS, *μιλφωσις*, a Greek word uſed by the ancient medical writers, as a name of the diſeaſe of the eyelids, by which the hairs fall off from them, and the edges become red and tumid.

MILL-REE, or MILLE-RAY, a Portugueſe gold coin, current for ſomewhat more than the Spaniſh piſtole.

The *millree* is thus called, as conſiſting of a thouſand REES. It is alſo called a *St. Stephen*, from the figure of that martyr impreſſed thereon.

They have alſo a *millree* of the little croſs, which in reality is only half the former; and whoſe value is that chiefly uſed in computations. See COIN.

MILOHYOIDÆUS. See MYLOHYOIDÆUS.

MILT, in *Anatomy*, a popular name for the SPLEEN.

MILT, or MELT, in *Natural Hiſtory*, the ſoft ROE in fiſhes; thus called becauſe it yields, by expreſſion, a whitiſh juice reſembling milk.

The *milt* is properly the ſeed, or ſpermatic part of the male fiſh.

The *milt* of a carp is reckoned a choice bit.

It conſiſts of two long whitiſh irregular bodies, each included in a very thin fine membrane. M. Petit conſiders theſe as the teſticles of the fiſh wherein the ſeed is preſerved: the lower part, next the anus, he takes for the veſiculæ ſeminales. Vide Mem. Acad. R. Scien. anno 1733. p. 291.

In the *milt* of a living cod-fiſh there are ſuch incredible numbers of thoſe ſmall animalcules found in the male-ſeed of all animals, that in a drop of the juice of it, no more in quantity than a ſmall grain of ſand, there are contained more than ten thouſand of them; and, conſidering how many ſuch quantities there are in the whole *milt* of one ſuch fiſh, it is not exceeding the bounds of truth to affirm, that there are more animals in one *milt* of it, than there are living men at one time upon the whole face of the earth. However ſtrange and romantic ſuch a conjecture may appear at firſt ſight, a ſerious conſideration, and calculation, will make it appear very plain. An hundred ſuch grains of ſand as here mentioned, will make about an inch in length; therefore in a cubic inch there will be a million of ſuch ſands.

The *milt* of one of theſe fiſhes is frequently about the quantity of fifteen cubic inches, it muſt therefore contain fifteen millions of quantities as big as one of theſe ſands; and if there be ten thouſand animals in each of thoſe quantities, there muſt be, in the whole, a hundred and fifty thouſand millions: which is a number vaſtly exceeding the number of mankind, even though we were to ſuppoſe the whole earth as populous as Holland. See Philoſophical Collections, p. 4. See *Fecundity of Fish*.

MILT *worſle*, or CETERACH *aſplenium*, in *Botany*, a plant nearly allied to the fern; being, in the Linnæan ſyſtem, a genus of the *cryptogamia filices* claſs. The leaves are ſtotched toward the ſide and downy; having a ſquamous duſt, in which, by the help of a microſcope, membranous capſulæ, or ſeed pods, lying cloſe to one another, are perceived; every one furniſhed with a little round rope, which, by its conſtruction, opening the fruit into two parts, pours forth certain very ſmall ſeeds; the root is fibrous. It grows upon old, ſhady, moiſt walls, in many parts of England; but it is rarely cultivated.—Linnæus reckons twenty ſpecies.

The leaves are recommended as a pectoral ſimilar to maidenhair; to which they have been frequently joined in infuſions and apozems; and likewiſe as an aperient in obſtructions of the viſcera. They poſſeſs likewiſe a diuretic virtue, and appear to gently carry off ſand, cleanſe the kidneys, and allay pains in the urinary paſſages. The way of uſing them is to drink infuſions of them in the morning, as tea, with the addition of ſuch other medicines as particular caſes may require. See CETERACH.

MILTOS, in the *Natural Hiſtory of the Ancients*, the name of what we call reddle, a red earth of the ochreous kind, uſed in painting. The Greeks uſed the word in a leſs determinate ſenſe, and called all the red earths by this name, with adjectives derived from the names of the places where they were found, &c. to denote their differences. See REDDLE.

MILVAGO, in *Ichthyology*, a name given by Geſner and ſome others, to a fiſh called by authors in general *milvus* and *cuculus*, and by ſome *lucerna*, and the FLYING *fiſh*. It is a ſpecies of the TRIGLA, and is called, by Ariſtot. the trigla with a ſnout biſid at the extremity, and the ſidelines forked near the tail.

MILUS, *μιλος*, a name given by the Greek writers to a plant uſed in garlands, and ſometimes to a tree. Theophraſtus evidently uſes it as the name of a tree, and Crato as that of a garland-herb.

MILVUS, in *Ichthyology*. See FLYING *fiſh*.

MILVUS, in *Ornithology*. See KITE, and BUZZARD.

MIME, MIMUS, a term in the ancient comedy, ſignifying a BUFFOON, or *mimic*, who acted by poſtures ſuitable to the perſon or ſubject he repreſented.

The word comes from the Greek *μιμεῖσθαι*, *imitator*, formed of *μιμέομαι*, *I imitate*. The ſame comedians were alſo ſometimes called *pantomimes*, becauſe of their counterfeiting all manner of poſtures and geſtures.

MIMESIS, *μιμησις*, in *Rhetoric*, a figure, whereby the words, geſtures, ſpeech, actions, &c. of another perſon are imitated. See IMITATION.

MIMOSA, in *Botany*. See SENSITIVE *plant*.

MIMULUS, in *Botany*, CYNOPHYNEUM, or MONKEY FLOWER, a genus of the *didynamia angioſpermia* claſs. It characters are theſe: the flower has a quadridentated, priſmatic, permanent empalement; it is of the lip or ringent kind, whoſe brim is divided into two lips; the upper lip is erect, divided at the top into two parts; the lower lip is broad and trifid, the middle ſegment being the leaſt, the palate convex and biſid; it has four ſlender ſtamina, two longer than the other, terminated by biſid kidney-ſhaped ſummits; and a conical germen, which turns to an oval capſule, with two cells, filled with ſmall ſeeds. Miller mentions only one ſpecies, which grows naturally in moiſt grounds in North America.—Linnæus enumerates two ſpecies.

MIMUSOPS, in *Botany*, a genus of the *octandria monogynia* claſs. Its characters are, that the empalement is compoſed of eight leaves; that the flower has fifteen petals; and that the fruit is an acuminated drupe.—There are two ſpecies.

MINA, *μνα*. The Attic *mina* was either ſummary or ponderal; in the firſt acceptation it was the ſixtieth part of a talent, and contained a hundred drachmæ, or denarii, amounting in our coin to three pounds four ſhillings and ſeven pence. *Mina*, conſidered as a weight, was alſo divided into a hundred drachmæ. See DRACHMA, and DENARIUS.

Mina was alſo a medicinal weight, conſiſting of ſixteen Roman ounces, anſwering to our avoirdupois pound, as appears by Dioſcorides and Galen, and Cleopatra in Coſmeticis.

There was alſo another *mina* more lately introduced, which conſiſted of 125 ounces. See COIN and WEIGHT.

MINAGNGHINIM, a pſaltatile inſtrument of muſic, among the Hebrews, which was a ſquare table of wood, fitted with a handle; over this table was ſtretched an iron chain, or hempen cord, paſſing through balls of wood or braſs, which ſtruck againſt the table, when the inſtrument was ſhook, and occaſioned a clear ſound,

which might be heard at a great diſtance. See Kircher's figure of it, in *Tab. Muſic. fig.* 9.

MINCA, a name given by the ancients to a very coarſe and bad kind of myrrh.

MINCHA, in the *Jewiſh Cuſtoms*, offerings of meal, cakes, or biſcuits, made in the temple of the Lord. The Seventy have ſometimes preſerved this word in their tranſlation; but inſtead of *mincha* they read *manna*, which doubtleſs was the received pronunciation in their time. We find *manna* in the ſame ſenſe, in Baruch i. 10. Levit. ii. 3 &c. See the Greek of Jerem. xvii. 26. Dan. ii. 46. 2 Kings viii. 5, 9. xvii. 7. xx. 12. 2 Chron. vii. 7. Nehem. xiii. 5, 9. &c. Calmet. Dict. Bibl.

MIND, *mens*, denotes a thinking or underſtanding being. See SPIRIT.

Philoſophers generally allow three kinds of *minds*, viz. *God*, *angels*, and the human *ſoul*. For a thinking being muſt either be finite or infinite: if infinite, it is *God*; and if finite, it is either joined with a human body, or not; if the latter, it is an *angel*; if the former, a *ſoul*.

The *human mind* is properly defined a thinking rational ſubſtance: by *thinking*, it is diſtinguiſhed from body; and by *reaſoning*, from God and angels, who are ſuppoſed to ſee and know things intuitively, without the help of deduction and diſcourſe.

MIND, *affection of the*. See AFFECTION.

MINDERERI *portus*. See VINEGAR.

MINE, in *Natural Hiſtory*, a place under ground, where metals, minerals, or even precious ſtones, are dug up.

As, therefore, the matter dug out of *mines* is various; the *mines* themſelves acquire various denominations; as *gold-mines*, *ſilver-mines*, *copper-mines*, *iron-mines*, *diamond-mines*, *ſalt-mines*, *mines of antimony*, *of alum*, &c.

For *gold* and *ſilver-mines*, the richeſt and moſt celebrated are thoſe of Peru and Chili, in America. *Iron-mines* are more abundant in Europe than elſewhere. *Copper-mines* are chiefly found in Sweden, Denmark, and England. *Lead* and *tin-mines* abound moſt in England and Wales. *Quickſilver-mines* in Hungary and Spain. *Diamond-mines* in the Eaſt Indies, and in the Braſils. *Salt-mines* in Poland, &c.

Metallic mines are chiefly found in mountains; though the reaſon thereof does not appear. It is probable, plains may abound as much therewith, would people dig deep enough. But plains are commonly cultivated; and beſide, the water will ſcarce allow them to be dug. Add, that the metallic veins always run either horizontal or oblique; and for that reaſon are eaſieſt found on the ſides of eminences. See LOAD, TRAINING, &c.

There are ſome *mines* wherein the metals are found at their firſt opening very crude and imperfect; which yet, in time, grow ripe and rich. Alonſo Barba relates, that in Potoſi, ſtones have frequently been at firſt thrown aſide, as not containing any thing conſiderable of metal; and yet have been found many years afterwards exceeding full thereof. Caeſalpinus aſſures us, that earths, which before yielded no metal at all, ſometimes became very fertile veins. In an iſland of the Tyrrhene ſea, after the *iron-mines* have been exhauſted, they ſtop them up about ten years; at the end whereof, it is ſaid, they find them as rich as before: many of theſe facts, however, are but ſlightly atteſted. *For the formation of mineral and metallic matters in mines*, ſee MINERAL.

The king by his prerogative hath all *mines* of gold and ſilver to make money; and where gold and ſilver in *mines* is of greater value, which are called royal mines. But by ſtatute no mines of copper or tin ſhall be adjudged a royal *mine*, though ſilver be extracted. 1 W. & M. c. 30. And perſons having *mines* of copper, tin, lead, &c. ſhall enjoy the ſame, although claimed to be royal *mines*; but the king may have the ore (except in Devon and Cornwall) paying to the owners of the *mines*, within thirty days after it ſhall be raiſed, and before removed, 16*d.* per ton for copper-ore waſhed, and made merchantable; for lead-ore 9*s.* per ton; tin or iron, 40*s.* &c. Stat. 5 W. & M. c. 6. If any perſon maliciouſly ſet on fire any *mine*, or pit of coal, he ſhall ſuffer death as a felon, by ſtat. 10 Geo. II. c. 32. Stealing ore out of *mines* is no larceny, except only thoſe of black-lead, the ſtealing ore out of which is felony without benefit of clergy, by 25 Geo. II. c. 10.

MINE-*adventurers*, *company of*, had its firſt riſe about the year 1690, when certain *mines* of lead and copper were found in South Wales, which were divided by the proprietors into twenty-four ſhares; and in 1693 ſubdivided into four thouſand and eight ſhares, for the term of twenty-two years and a half; to which term five years more were added in 1698, and the affairs of the company regulated by a new conſtitution. In 1704, queen Anne granted a charter of incorporation to this company, in conſequence of which ſeveral new ſhares were added, ſo that the whole number amounted to ſix thouſand and twelve. However, the intereſts of this corporation were ſo ill managed, that the proprietors and creditors petitioned parliament in 1710, and a committee of the houſe of commons was appointed to enquire into its ſtate. The reſult of the enquiry was a cenſure on the principal managers; and though, in 1711, a law was paſſed for the better regulation of the company, and the relief of the creditors and proprietors, nothing could preſerve it from ſinking.

MINE, in the *Art of War*, denotes a ſubterraneous canal or paſſage dug under the wall or rampart of a fortification intended to be blown up by gunpowder.

The paſſage of a *mine* leading to the powder is called the GALLERY. Theſe paſſages or galleries made within the fortification, before the place is attacked, and from which ſeveral branches are carried to different places, are generally four feet wide, and five feet high, and the earth is ſupported from falling in by arches and walls, as they are to ſerve for a conſiderable time; but when *mines* are to be uſed in a ſhort time, the galleries are only about three feet wide and five high, and the earth is ſupported with wooden frames or props. When the gallery is carried on to the place where the powder is to be lodged, called the CHAMBER, the miners make this generally of a cubical form, large enough to hold the wooden box, which contains the powder neceſſary for the charge: this box is lined with ſtraw and ſand-bags, to prevent the powder from contracting any dampneſs. The chamber is ſunk ſomewhat lower than the gallery, unleſs the beſieged can raiſe the water in the ditch, and incommode the gallery; in which caſe the chamber is made higher than the gallery, that the water may not be let in and ſpoil the *mine*. The line, drawn from the center of the ſpace containing the powder, perpendicular to the neareſt ſurface, is called the *line of leaſt reſiſtance*; the pit or hole, made by a *mine* when ſprung, is called the *excavation*. The fire is conveyed to the *mines* by a pipe or boſe, made of coarſe cloth, whoſe diameter is about an inch and a half, called *fauciſſon*, extending from the chamber to the entrance of the gallery, to the end of which is fixed a match, that the miner who ſets fire to it may have time to retire before it reaches the chamber. In order to prevent the powder from becoming damp, the fauciſſon is laid in a ſmall trough, called *auget*, with ſtraw in it, and round the fauciſſon, with a wooden cover nailed upon it. There are various kinds of *mines*, which acquire different names; as royal *mines*, ſerpentine *mines*, forked *mines*, as their paſſages are ſtrait, oblique, winding, &c. The *mines* made by the beſiegers in the attack of a place are ſimply called *mines*, and thoſe made by the beſieged COUNTER-*mines*. They are both made in the ſame manner, and for the like purpoſes, viz. to blow up their enemies and their works; only the principal galleries and *mines* of the beſieged are uſually made before the town is beſieged. The beſieged generally make a great many ſmall *mines* under the glacis, of about ſix, ſeven, or eight feet deep under ground, which are called *fougaſſes* or *fougades*. They make likewiſe another ſort, called *coffers* or *caiſſons*, which are a kind of wooden boxes three or four feet long, and a foot or eighteen inches wide, which they bury four, five, or ſix feet under the glacis, and about four yards diſtant from each other.

MINES, *hiſtory of*. It is obſerved by writers on this ſubject, that *mines* were in uſe long before the invention of gunpowder; for the ancients made galleries or ſubterraneous paſſages under the walls of places, and ſupported them with ſtrong props; filling the interval with all kinds of combuſtibles, which being ſet on fire burnt their props, and, the walls being no longer ſupported, fell, whereby a breach was made. The beſieged alſo made uſe of ſimilar paſſages from the town under the beſiegers machines, with which they battered the walls, in order to deſtroy them. But the art of mining has received great improvements ſince the invention of gunpowder. The firſt *mines* which we read of, ſince the diſcovery of gunpowder, were uſed, in 1487, by the Genoeſe, in the attack of Serezanella, a town belonging to Florence; however, as theſe failed, they were neglected for a conſiderable time. The firſt ſucceſsful application of the blowing of *mines* in ſieges was in the kingdom of Naples, in the year 1503, when Pietro de Navarre by this means poſſeſſed himſelf of a fort garriſoned by the French. The firſt celebrated uſe of theſe *mines* in open war, the progreſs of the beſiegers was in the years 1667, 1668, 1678, at the ſiege of Candia; though they had been often practiſed in the defence of places before, in a leſs memorable manner; for by the aſſiſtance of this invention principally, the city of Candia kept the whole power of the Ottoman empire at bay for three years ſucceſſively. Since that time the advantage of *counter-mines* have been better underſtood. The laſt eminent inſtance

of

of their great utility was in the defence of Turin, in 1706; for so effectually were the besiegers travelled thereby, that, after near four months of open trenches, they were not in the possession of more than the counterscarp, and even then, seleven pieces of their cannon were blown up by the defendants but three or four days before the place was relieved.

The first publisher writer on *mines* was the celebrated M. Vauban: he was succeeded by M. de Valliere, one of the greatest masters in the art of mining; who, uniting theory with experiment, discovered, by measuring several excavations, that the pit or hole made in the earth, when the *mine* is sprung, was not an inverted cone (*Tab.* VIII. *Fortification, fig.* 49) nor a frustum of a cone (*fig.* 50.) as Vauban and others had supposed, but nearly a parabolid (*fig.* 51.); and his tables were computed according to that figure. It has been generally admitted by miners, that the diameter of the pit or hole made by the *mine* was always twice the line of the least resistance, and that this diameter should never exceed this proportion. But M. Belidor undertook to remove this prejudice; and however generally it may still prevail, he seems to have proved by many experiments, which have since been repeated by others, that the diameter of the hole made by a *mine* may be increased to any length in regard to the depth of the *mine*.

MINES, *theory of.* The estimation of the proper quantity of powder with which a *mine* is to be loaded in any kind of soil, or at any depth under ground, in order to produce any proposed effect, is the most difficult part of the whole art of mining. This depends not only on the quantity of earth to be blown up, but likewise on the tenacity of the different soils in which the *mines* are made. The quantity of earth to be raised depends on the figure of the excavation; for if this is known, the solid content may be determined by geometry; and by weighing exactly a cubic foot of that soil, we can easily discover what weight is to be raised; and by knowing what quantity of powder is required to raise a certain weight, the tenacity of the parts may also be had, by making a *mine* so as to produce a good effect; and subtracting the quantity of powder, necessary to raise the weight of the solid from the charge of the *mine*, the remainder would be the quantity necessary to overcome the tenacity. It is, however, disputed, as we have already observed, what the figure of the excavation is: it was at first imagined to be an inverted cone, as ACB (*fig.* 49.) whose vertex is in the center of the chamber, and the radius of its base AD equal to its axis CD; but this being found to allow too small a charge, it was next supposed to be a frustum of a cone, as AEFB (*fig.* 50.) whose lesser base EF is equal to the line CD of least resistance, and the greater AB equal to twice that line. On this last supposition, said to be confirmed by the experiments of M. Maigrigny, under M. Vauban, near Tournay, miners have computed their tables of the quantities of powder necessary for charging *mines* at different depths.

However, M. Belidor disputed the conclusions of Maigrigny: whose experiments were examined by direction of the chief commander of the artillery of La Fere, in the construction of more than a hundred and fifty *mines* between the years 1725 and 1730. In the course of this enquiry, seven *mines* were made, whose line of least resistance was ten feet, and loaded with the following quantities of powder, viz. the first with 120 lb; the second with 160 lb; the third with 200 lb; the fourth with 240 lb; the fifth with 280 lb; the sixth with 320 lb; and the seventh with 360 lb. These *mines* being sprung one after another, and their excavations examined, the diameters of their bases were found to be as follow: that of the first 22 feet; the second, 26 feet; the third, 29 feet; the fourth, 31½ feet; the fifth, 33½ feet; the sixth, 36 feet; and the seventh, 38 feet. These experiments invalidated the principles of Maigrigny; nevertheless miners have still doubted, whether the diameter of the excavation can be made greater than double the line of least resistance, or whether the excavation itself will not become like a well or pit when overcharged. As to the true figure of the excavation, this was discovered by M. de Valliere, and ascertained by others after him, to be very nearly a paraboloid, as AEB (*fig.* 51.) having the center of the powder or charge in the focus C, CD the line of least resistance, AB the diameter, and CA the radius. Mr. Muller, however, observes, that, though the figure of the excavation is a paraboloid, the quantity of the earth to be blown up should be estimated by the part ALMB, cut off by a plane LM, passing through the focus or center C of the chamber, parallel to the horizon AB; the other part LEM being occasioned by the force of the powder pressing downwards; because, he says, the explosion of gunpowder, acting on all sides alike, must condense the solid under the chamber from L to M, by its pressure downwards, so long as it presses the earth above LM upwards; and it cannot be said, that any particle of earth under the horizontal line LM can be drove upwards. In order to find the content of this solid, let $EK=EC=\frac{1}{2}P$, or the parameter; and it appears from the well known properties of the PARABOLA, that $AD^2=ED\times P$; $LM=P$, and $CA=KD$. And in the right-angled triangle CDA, $CD^2+DA^2=CA^2=KD^2$; and, therefore, $\sqrt{CD^2+DA^2}=KD$; whence, if CD and DA are given, the line KD, and consequently CK, or its equal CL, will be known; and, therefore, if the line of least resistance CD, and the radius DA of the base are given, the parameter may be found. Moreover, the solid content of the PARABOLOID is equal to half the cylinder of the same base and altitude; if r expresses half the circumference, whose radius is unity; i. e. if $r=1.57$; then, because $1:2r$, or the radius to the circumference as the squares of the radii CL, DA, are to the areas of their circles; we have $r\,ED\times AD^2-r\,EC\times CL^2$, will express the solid required. But if P expresses the parameter LM, then will $P\times ED=AD^2$, and $P\times CE=CL^2$, and these values substituted in the expression of the solid, give $r\,P\times ED^2-r\,P\times EC^2$: or, because $ED=EC+CD$, and $KD=CD+2\,EC$, we shall have this expression reduced to $r\,P\times CD\times KD$. But as r is a constant number, it may be neglected in comparing the solids; and then $P\times CD\times KD$, will be the expression of the solid. And when two excavations are compared together, which have the same line of least resistance CD, the solid will be expressed by the rectangle $P\times KD$. Hence if the solid, or the quantity of earth to be raised, and the line CD of the least resistance be given, the parameter P may be found; and having the parameter and the line CD, the equation $P\times ED=AD^2$, will give the radius AD of the base. For if $CD=c$, and the given solid $ALMB=a$, then, because $CE=\frac{1}{2}P$, the expression $P\times CD\times KD$, will give $Pc\times\frac{1}{2}P+cc=a$, or $PP+2Pcc=2a$, and $PP+2Pc=\frac{2a}{c}$, to which adding cc, we shall have $PP+2Pc+cc=\frac{2a}{c}+cc$; and $P+c=\sqrt{\frac{2a}{c}+cc}$.

In comparing *mines* together, which have the same line of least resistance, the rectangle $P\times KD$, gives $PP+2Pc=2a$, to which adding cc, we shall have $PP+2Pc+cc=2a+cc$, whose square root is $P+c=\sqrt{2a+cc}$. By means of these equations, all the different problems relating to *mines* are easily solved, on the supposition, that the forces of powder are proportional to their quantities, and, therefore, the charges also proportional to the quantities of earth to be raised in the same sort of soil, i. e. in soil of the same density and tenacity. Some writers, however, assert, that the elastic force of powder is greater, in proportion, in larger quantities than in small ones, which Mr. Muller denies; and M. Belidor gives another reason for diminishing the charges of *mines*, as the earth to be raised increases; which is, that not only the weight of the earth to be raised is to be considered, but likewise the pressure of the atmosphere over the surface of the excavation, which pressure is as the bases of the excavation, and these as the squares of the diameters; whereas the weights of similar solids are as the cubes of these diameters; and, therefore, this pressure being less, in proportion, in larger bodies than in smaller, the charges ought rather to be lessened in large *mines* than in the small. But this reasoning seems to be contradicted by experiments.

In order to know the quantity of powder necessary for blowing up a *mine* in a particular soil, several *mines* are to be made in it, having their lines of least resistance equal, but loaded with different quantities of powder, till one is found to have the desired effect. When this is found, the diameter of its base must be measured with the greatest accuracy, and likewise the line of least resistance; and when these lines are determined, the parameter P of the parabola is found by the equation $KD=\sqrt{AD^2+CD^2}$; and, having the parameter given, the quantity of earth or solid is found by the solid $P\times CD\times KD$, or by the rectangle $P\times KD$, as the lines of least resistance are different or the same. This solid, and the charge of the *mine*, will serve to find the effect of any other *mine* made in the same soil when the charge is given, or to determine the charge, so that the diameter of the base shall be of any given length, by means of the equation $P\times ED=AD^2$. The same being performed in all the different soils, which generally occur in making *mines*, will serve to make *mines* of any depth, or placed in any soil.

The miners divide the different soil into five species.

1. loose earth or sand.
2. common middling light soil.
3. loom or strong soil.
4. potters clay, or stiff soil.
5. clay mixt with stones.
6. all kind of masonry.

into

It has been found, that a cubic foot of the first weighs 95lb; of the second, 124; of the third, 126; of the fourth, 135; and 160 of the fifth. But as to masonry, it cannot be determined to any degree of exactness, as depending on the different kinds of stones or bricks of which they are made.

It is pretended, that there are nine pounds of powder required to raise a cubic toise of the first kind; 11 of the second; 13 of the third; 15 of the fourth; 18 of the fifth; and 20 or 25 to raise a cubic toise of masonry above ground; and 35 or 40 for raising the same quantity under ground.

These are the French weights and measures, which being reduced into English, give 8lb of powder for the first kind of soil; 9.8 for the second; 11.6 for the third; 13.4 for the fourth; 16 for the fifth; 18 or 22.3 for the masonry above ground; and 31 or 35 for raising the same quantity under ground.

In the second volume of M. Vauban's Attack and Defence of Places, he says, that the following rules never fail.

A cubic toise of common earth requires 14 pounds of powder to be raised.

Stiff sand or loom, which may be dug without being supported, requires 17 pounds per toise.

Mixt earth requires 18 pounds per toise.

Potters clay or stiff soil, 19 pounds per toise.

Fat or stiff earth mixt with pebble stone, 22lb.

Wet sand, which cannot be dug without being supported, 15lb.

These rules of Mr. Vauban make therefore the charges greater than those of later miners.

But this is a matter which must be decided by experiments; and when these are made with sufficient exactness, it will be easy to find the proper charge of a *mine*, for as the diameter of its base be of any given length; or when that length is given, to determine the charge required. E. g. Let it be required to find the diameter of a *mine* made in the second sort of soil; which being loaded with 100lb of powder, say, if 11 pounds raise a cubic toise, or 216 cubic feet of earth, how much will raise 100lb; the fourth term, which is 1964, will be $=a$; and $2a=3928$: and supposing the line of least resistance CD to be 10 feet, then will $c=10$; hence the equation $c+P=\sqrt{\frac{2a}{a}+cc}$, will give $c+P=\sqrt{402.8}$ $=20$; or $P=10$, and $EC=\frac{1}{2}P=2.5$: $ED=12.5$; whence the equation $P\times ED=AD^2$, gives 10×12.5 $=125=AD^2$, or $AD=11.2$ nearly.

But to shew how far this theory agrees with the experiments mentioned before, we may suppose the first to be true, and from thence proceed to find what the diameters of the bases of the others will be. All the lines of least resistances of these *mines* were ten feet each; the diameter of the base of the first *mine* was found to be 22½ feet; so that $AD=11.33$, or $=11.4$. $CD=10$; these values being substituted in the equation $KD=\sqrt{CD^2+AD^2}$, will give $KD=\sqrt{229.96}=15.16$; and $2KC=P=10.32$; hence these values being substituted in the rectangle $P\times KD$, because the line of least resistance is here always the same, gives $10.32\times 15.16=$ 156.5, for the solid, which must be remembered, because it is the standard number whereby the other solids are determined.

Now if 120lb gives 156.5, how much gives the charge 160lb of the second for its solid, the fourth term gives $208.^1=a$, and $2a=417.^2$; this value, as well as that of $c=10$, being substituted in $P+c=\sqrt{2a+cc}$, gives $P+c=\sqrt{517.4}=22.7$; hence $P=12.7$, $EC=\frac{1}{2}P=3.2$, and $ED=12.2$. Now these values being substituted in $P\times ED=AD^2$, give $AD^2=167.64$, and $AD=13$ nearly; and as AB has been found by measurement to be about 26, it shews that this computation answers very nearly the experiment.

If as the charge 120 of the fifth is to the charge 200 of the third, so is the solid 156.5 of the first to the solid of the third; we shall have $a=260.84$, or $2a=521.68$; and as $c=10$, the equation $P+c=\sqrt{2a+cc}$ gives $P+c$ $=\sqrt{621.68}=24.93$ nearly; hence $P=14.93$, $\frac{1}{2}P=$ $EC=3.73$, and $ED=13.73$; these values being substituted in $P\times ED=AD^2$, give $AD=14.32$, and $AB=28.64$; which answers nearly the experiment; it was found that $AB=29$ nearly.

If we proceed thus with regard to the 4th, 5th, 6th, and 7th experiments, we shall find the diameters of the base to be as follows: that of the 4th, 31.2; that of the 5th, 33.2; the 6th, 35.3; and 10ft of the [illegible] answers pretty near the experiments.

In this method of constructing *mines*, [illegible] be made, whatever be the line of [illegible] making this line small, and loading the powder, the inconvenience of a large [illegible] affords lodgment to the besiegers, [illegible] the shafts and galleries are blown made. [illegible] may be placed under one another, by [illegible] same spot of ground may be blown up several times.

If it were required to make a *mine* in the same sort of soil as that in which the seven experiments mentioned before were made, so that the line of the least resistance shall be equal to the radius of the base, and each of ten feet, and to find the quantity of powder necessary for its charge.

Because $AD=CD=10$, the equation $KD=\sqrt{AD^2+CD^2}$, will give $KD=\sqrt{200}=14.14$; hence $P=8.28$; these values being substituted in $P\times KD$, will give 117 nearly, for the solid; then if we say, as the solid 156.5, of the first experiment, is to the solid 117, so is the charge 120 to the charge required, it will be 90lb nearly. But if it was required to find the quantity of powder necessary to raise a cubic fathom, or 216 cubic feet of this soil; then because $CD=10$ has been neglected in the solid 156.5, of the first experiment, as likewise the ratio r, therefore the quantity must be multiplied by $r\times 10$; or because $r=1.57$ by 15.7, which will give 2457; then if we say, as 2457 requires 120lb of powder, how much will 216 require; and the fourth term, which is 10.5lb, will be the number sought. From whence it appears, that the soil, in which these experiments were made, was a light sort of soil, somewhat lighter than that which is taken by the miners for the second sort.

M. De Valliere supposes, in his table, inserted below, that a *mine*, whose line of least resistance and radius of the base are each ten feet, requires 93⅓lb for its charge. Now, if it be required to find what kind of soil these mines are made in, by substituting the number for CD, AD, in the equation $KD=\sqrt{AD^2+CD^2}$, we shall have $KD=\sqrt{200}=14.14$, and $P=8.28$; now these values being substituted in $r\times P\times CD\times KD$, we shall have $15.7\times 8.28\times 14.12=1838$; then if we say, as 1838 is to 93⅓, so is 216 to 11. This fourth term will express the number of pounds of powder required to raise a cubic fathom of the same sort of soil, which therefore is the second sort.

The preceding computations have been made of French weights and measures, to shew how nearly the foregoing theory agrees with the experiments made at La Fere. It remains now to apply it to our own weights and measures; because eight pounds of powder will raise a cubic fathom of earth of the first sort; if we say a cubic fathom, or 216 cubic feet is to eight pounds, as 1838 cubic feet is to 68.074 pounds, this fourth term will be the charge of a *mine*, whose line of resistance is ten feet as well as the radius of the base: in the same manner are found the charges of the same *mine* in the rest of the soils. But the shortest way of computing tables is to subtract the logarithm of 216 from that of 1838, which gives 0.928917; now if to this logarithm we add those of 8, 9.8, 11.6, 13.4, 16; the weight of the powder required to raise a cubic fathom of the different soils, found before; we shall have 1^0 8.3208, 2^0 0.2112, 3^0 9.9435, 4^0 0.0699, 5^0 1.4301, for the logarithms of the charges of a *mine* whose line of least resistance is 10 feet, and the diameter of the base 20.

Valliere's TABLE for the Charges of *Mines*.

Diameters of the Chambers	Charges of Powder	Diameters of the Chambers	Charges of Powder	Diameters of the Chambers	Charges of Powder	Diameters of the Chambers	Charges of Powder
Feet.	lb. oz.	Feet.	lb. oz.	Feet.	lb. oz.	Feet.	lb. oz.
1	0 5	11	123 12	21	868 5	31	
2	0 11	12	164 -	22	908 4	32	
3	2 2	13	205 13	23	1140 10	33	
4	4 6	14	257 4	24	1296 0	34	1680 12
5	11 11	15	316 4	25	1518 9	35	2029 8
6	20 4	16	384 -	26	1647 12	36	2376 0

8	48 -	18	516 12	28	2138 0	38	3144 -
9	68 1	19	643 9	29	2286 7	39	3568 4
10	93 12	20	760 -	30	2520 4	40	4000 -

By this conſtruction the radii of the baſes being always equal to the lines of leaſt reſiſtances, the ſolids are ſimilar, and therefore are to one another as the cubes of their axes; that is, as the cubes of the lines of leaſt reſiſtances. So that taking any one of the charges to be true, the others will be found by ſaying, as the cube of the axis whoſe charge is given is to its charge, ſo is the cube of the axis of any other *mine* to its charge.

For example, let the charge 93¾ of the *mine*, whoſe line of leaſt reſiſtance is 10 feet, be given; and it be required to find the charge of any other *mine* whoſe line of leaſt reſiſtance is given, ſuppoſe 15: then ſay, as the cube 1000 of 10 is to the cube 3375 of 15, ſo is the charge 93¾ to the charge required, which is 316-4, or 316 pounds, 6 ounces, which is 2 ounces more than in the table. In the ſame manner is found the charge of a mine whoſe line of leaſt reſiſtance is 20; or becauſe 20 is double of 10, the cube of 20 will be octuple the cube of 10; and therefore 8×93¾, or 750 pounds, will be the charge for that mine.

A TABLE of the Charges of *Mines* according to Muller's Theory.

Diameter	Charge	Diameter	Charge	Diameter	Charge
Feet 22	lb 150	Feet 42	lb 639	Feet 62	lb 1518
24	181	44	711	64	1621
26	217	46	773	66	1741
28	255	48	857	68	1842
30	297	50	946	70	1980
32	344	52	1020	72	2098
34	396	54	1115	74	2243
36	452	56	1205	76	2372
38	502	58	1309	78	2501
40	560	60	1406	80	2648

In this table the line of leaſt reſiſtance is ſuppoſed to be always 10 feet, and the charges producing the openings at the ſides of them from 22 feet to 80. It is ſuppoſed that the charge 93¾ of a *mine*, whoſe line of leaſt reſiſtance and radius of the baſe are each 10 feet, is given, and from thence all the reſt are computed by means of theſe equations, $KD=\sqrt{AD^2+CD^2}$, and $P\times KD^3=a$; and by comparing the diameters of the baſes found by means of theſe equations, to be rather leſs than thoſe found by experiments, it is preſumed that the diameters marked in this table will not be found leſs, but rather greater in practice.

In order to find the ſize of the boxes, generally made cubical, in which the powder is lodged; as a cubic foot of common powder weighs about 55 pounds, if we ſay as 55 is to unity, ſo is any other quantity to its cube; i. e. if the given quantity of powder be divided by 55, the quotient will be the cube required, and its cube root will be the length of the ſide of the box. The box muſt always be made a fourth bigger than it ſhould be, on account of the ſtraw and ſand-bags put in it, for keeping the powder free from wet; ſo that if the quantity of powder be 360 pounds, the fourth part of it, or 90, muſt be added, and the ſum 450 divided by 55, whoſe quotient is 8.1818, and the ſquare root of this, or 2.86 feet, or 34 inches, will be the ſize required. If the chamber happens to be placed on a rock, or any other hard ſubſtance, the force or action of the powder downwards, meeting with a great reſiſtance, will be employed in raiſing the earth upwards; and, conſequently, the effect of the *mine* will be much greater than that produced by the ſame quantity of powder, placed on a ſofter ſubſtance. On which account, if a platform of ſtrong planks were made under the chambers, there would be a leſs quantity of powder required for the charge of the *mine*. When the *mine* is properly loaded, the gallery is ſtopped up with ſtones, caſks, and dung, well rammed, five or ſix feet farther from the chamber than the length of the line of leaſt reſiſtance. And for preventing the *mine* from burſting through the gallery, and to make it have its effect upwards, the gallery is made with one or two turnings, at right angles to each other, and ſtrongly ſecured with buttreſſes and planks, and the intervals rammed with ſtones and earth.

Many writers have eſtimated the operation of *mines* on the falſe ſuppoſition, that their entonnoir, or excavation, is the fruſtum of a cone; and therefore, in order to eſtimate the weight of the matter to be blown up, they have only to compute the ſolidity of ſuch a fruſtum in cubic fathoms, and to multiply the number of fathoms by the number of pounds of powder neceſſary for raiſing the matter it contains; and if this cone contains matters of different weights, to take a mean between them all; always having a regard to their degree of coheſion. As to the diſpoſition of *mines*, there is one general rule, which is, that the ſide towards which one would determine the effect, be the weakeſt; but this varies according to occaſions and circumſtances.

MINES, *different ſorts of*. A *mine* which has only one chamber is called a *ſingle mine*, as A, *fig.* 52. If it has two chambers, it is called double, as *fig.* 53. and if it has three, triple, as *fig.* 54. &c. the names being taken from the number of chambers. If a ſingle *mine* is made under the rampart, to make breach, the entrance O, *fig.* 52. muſt not be oppoſite to the place where the chamber is deſigned to be, but on one ſide or other; and the gallery with two turnings, that it may be ſtopped with greater ſecurity, and that the diſtance of the entrance O to the chamber A may be greater than the length of the line of leaſt reſiſtance; otherwiſe the *mine* would have its effect that way. It muſt alſo be obſerved, that the chamber is placed in the middle of a counterſcarp, by which means it will make a greater breach than if it were placed in the earth behind the wall. When a double *mine* is made under the rampart for making breach, the entrance O, *fig.* 53. is made, as nearly as can be gueſſed, in the middle, between two counter-forts; the gallery being carried quite through the wall in a direct line, turns afterwards to the right and left, in the form of a T; from whence it is alſo called a T *mine*; and the chambers are alſo placed in the next counter-forts, but exactly at equal diſtances from the direct gallery: this double *mine* will make a much larger breach than the ſingle one, and it is for that reaſon preferred to any other.

But when a triple *mine* is to be made under the rampart, the opening O, *fig.* 54. is to be made directly oppoſite to the counter-fort, if poſſible, and carried directly through the wall, and turned to the right and left in the ſame manner as the former; and the chambers A, B, at both ends, are placed in the two adjacent counter-forts. As to the gallery of the third, C, it is carried round the middle counter-fort, and the chamber placed under its extremity; this laſt is generally charged with fifty pounds of powder more than either of the others; but great care muſt be taken to carry the aogee of this laſt chamber in zig-zags, ſo as to be equal in length to that of the chamber B, otherwiſe the fire would not reach them all three at the ſame time, and thereby the chamber C not take fire, which ſometimes happens, and then the effect does not anſwer the expectation.

There are ſeldom or ever more made than a triple under the ramparts in ſieges; but when a work is to be demoliſhed, they make then as many as will demoliſh a whole face at once; which is done by giving the fire to all at the ſame time; that is, all the laucilions are brought into one, and ſo contrived, as that their parts from the chambers to the common junction may be exactly equal. Muller's Syſtem of Artillery, &c. vol. ii. part iii. p. 206, &c.

MINE, *chamber of a*. See CHAMBER and MINE.

MINE, *counter*. See COUNTER-*mine*, and MINE.

MINE, *gallery of a*. See GALLERY and MINE.

MINE, *knight of the*, is a military honour, anciently conferred on perſons who had diſtinguiſhed themſelves in engagements in *mines*.

MINE-*ſhips*, are ſhips filled with gunpowder, incloſed in ſtrong vaults of brick or ſtone, to be fired in the midſt of an enemy's fleet. See FIRE-*ſhip*.

MINE is alſo a French MEASURE.

MINE-*dial* is a box and needle, with a braſs-ring divided into 360 degrees, with ſeveral dials graduated thereon; generally thus made for the uſe of *miners*.

MINERA, in *Medicine*, the ſeat, or rather matter of a DISEASE.

The term is applied by ſome authors to thoſe parts of the body wherein there are collections and concervations of humours made; which, hardening, form obſtructions, and produce diſeaſes.

In this ſenſe we ſay, the *minera morbi*, &c.

MINERAL, in *Natural Hiſtory*, is ſometimes uſed in the general for FOSSIL; and applied to any body, ſimple or compound, dug out of a ſubterraneous place or *mine*, from which it takes the denomination.

In this ſenſe, metals, ſulphurs, foſſil ſalts, ſemi-metals, &c. are *minerals*.

On this principle, they divide *minerals* into two claſſes; the one *fuſible*, and *malleable*; i. e. which melt with fire, and ſtretch on the anvil; which are what we properly

call METALS. The others want those two properties; and are what in the ſtricteſt ſenſe we call *minerals*.

Some divide *minerals* into *ſimple* and *compound*. To the firſt belong *ſtones*; *ſalts*, as alum, nitre, &c. *inflammable minerals*, as ſulphur and bitumen; and *metals*, as gold, &c. Other more accurate writers refrain the word *miner al* to what we otherwiſe call *ſemi-metal*; as antimony, cobalt, &c.

MINERAL, in this ſenſe, may be defined a compound foſſil, wherein there is ſomething diſcovered, in all reſpects like metal, only that it is not malleable; joined or compounded with ſome other foſſil, as ſalt, ſulphur, ſtone, or earth.

Such are *antimony*, *cinnabar*, *biſmuth*, *calaminaris*, *vitriol*, *pyrites*, *marcaſſite*, *cobalt*, *zaffer*, the *magnet*, *lapis hæmatites*, and *armenus*. See each under its proper article.

Some attribute the formation of *minerals* to the action of the ſun without; ſome to the central fire within; and ſome think the cold does all by uniting, condenſing, and congealing certain juices of the earth.

Deſcartes takes metals to have been formed from the beginning of the world; and to have ranged themſelves, by the laws of gravity, about the centre. In proceſs of time, he ſuppoſes theſe to have been corroded by the acid ſalts, &c. and abundance of the parts thereof carried up along with thoſe ſalts by the ſubterranean heat, and depoſited in divers parts of the earth.

Mont Tournefort ſuppoſes ſeeds of *minerals*, as of animals and vegetables. Every thing, according to him, comes from eggs, even ſtones; and the largeſt rocks, he thinks, were originally no more than grains of ſand. See his ſyſtem more at length under the article STONE.

The alchemiſts maintain, that metals proceed from a certain primum ens, or firſt ſeed of metals, which, they ſay, is a kind of moiſt vapour, or gas, that changes the earth and juice it meets with in a vein into a *mineral* body or ſubſtance; and thence converts the *minerals* into ores or metals, by a continued fermentation or elaboration in the mines, cauſed by the archeus, or heat that acts in the veins, as it proceeds from the centre of the earth. But this doctrine of *mineral* fermentation is poſitively denied by the celebrated Boerhaave, who, in his Hiſtory of Fermentation, aſſerts, that it belongs only to the vegetable kingdom. Others maintain, that all metals and *minerals* were at firſt created in the very ſame ſtate and nature, in which they are always found, without undergoing any kind of alteration. The moſt common opinion, among the miners in Cornwall, is, that crude immature *minerals* nouriſh and feed the ores, with which they are intermixed in the mines; and that the *minerals* themſelves, will, in proceſs of time, be converted into ores productive of thoſe metals, to which they have the neareſt affinity, and with which they have the greateſt intercourſe. Others, as M. Geoffroy, contend that METALS, &c. may be the reſult of a mixture of certain matters, which had nothing metallic in them. Thus, in the aſhes of all vegetables we find a ſurfuginous matter, which the loadſtone attracts; and yet it will hardly be ſaid, that iron exiſted in the plants. We ſee no ſigns of iron in clay, work it in what manner you will; and yet add to it linſeed-oil, and by fire you will procure IRON: the like may be ſaid of divers other matters.

Hence it is probable, metals may be formed by a mere combination of different ingredients; much like ſulphur, which we all know is made by adding an inflammable principle to a vitriolic ſalt. The earth may every where abound with theſe matters, which are continually circulating through its pores and canals, and which, meeting with an earth homogenous to them, fix thereto; and commence *minerals*.

Mr. Price, in his Mineralogia Cornubienſis, p. iv. ſuppoſes it moſt reaſonable to conclude, that metals were made and implanted in veins at or very ſoon after the creations of the world: but that they are ſubject to a degree of fluctuation in common with all matter; approaching to, or receding from their ultimate degree of perfection, either quicker or ſlower, as they are of greater or leſs ſolid and durable frame and conſtitution. He ſuppoſes, that in every metal there is a peculiar magnetiſm, and an approximation of particles, ſui generis, by which its component principles are drawn and united together; particularly the matters left by the decompoſition of the waters paſſing through the contiguous earth or ſtrata, and depoſited in their proper *nidus*; till by the accretion of more or leſs of its homogeneous particles, it may be denominated either rich or barren.

The *minerals*, metals, and ſtones, lie in beds; and have done ſo ever ſince the flood, if not from the creation; yet it is highly probable they have a faculty of growing in their reſpective beds; and that, as their beds are robbed and emptied by miners, ſo after a while they recruit again. Thus vitriol, Mr. Boyle thinks, may grow by the help of the air, and that alum does the ſame. We are aſſured (ſays that author) by the experienced Agricola, that the earth or ore of alum, being robbed of its ſalts, will, in tract of time, recover them again, if expoſed to the air.

As for metals, there is good reaſon to [illegible] likewiſe, from what has been alledged [illegible] his obſervations about the growth of [illegible] cularly as to the growth of iron. To [illegible] brings from Pliny, Falloppius, Cæſalpinus, [illegible] others, we may add, that in the foreſt of Dean, in Glouceſterſhire, the beſt iron, and in the greateſt quantities, is found in the old cinders, which they melt over again. This ſome impute to the negligence of the former maſters in not exhauſting the ore. And Dr. Derham thinks it rather owing to the new impregnations of the old ore, or cinders, from the air, than to any ſeminal principle in the ore itſelf.

The chemiſts generally take *minerals* to be nothing elſe but imperfect metals, and imperfect metals to be perfect ores, which, not having arrived at maturity, may be perfected by chemical operations, and raiſed to perfection. This agreeable, but fatal deluſion, has given riſe to the ſect of philoſophers who ſtudy the philoſopher's ſtone.

In the Engliſh tranſlation of the Dictionary of Chemiſtry, art. *ores*, we have ſome ingenious conjectural remarks, concerning the formation of *minerals*. Theſe ores, it is ſaid, which are found under water, upon the ſurface of the earth, in fiſſures of mountains and ſubterranean cavities, accumulated, but not accreted to the contiguous rocks, ſeem from their looſe, unconnected, broken appearances to have been conveyed by alluvion.

All martial ochres have probably been ſeparated from vitriolic ferruginous waters, either ſpontaneouſly or by calcareous earth; and theſe waters ſeem to have acquired their metallic contents by diſſolving the vitriol which is produced by the ſpontaneous decompoſition of martial pyrites. The ochres of copper, zinc, and perhaps of ſeveral other metals, have probably been precipitated from vitriolic waters by ſome ſubſtance, as calcareous earth more diſpoſed to combine with acids; and theſe vitriolic waters have probably been rendered metalliferous, by diſſolving the vitriols produced by accompoſition of cupreous pyrites, and of the ore of zinc called blend; for theſe *minerals* are not, as martial pyrites is, ſuſceptible of decompoſition ſpontaneouſly, that is, by air and moiſture.

The metalliferous nodules and ſpots ſeem to have been inſtilled in ſtones while theſe were yet ſoft. Perhaps the metalliferous and lapideous particles were at once diſſolved and ſuſpended in the ſame aqueous menſtruum, and during their concretion, cryſtallized diſtinctly, as different ſalts do, when diſſolved in the ſame fluid.

The earths and ſtones uniformly coloured by metals, were alſo probably in a ſoft ſtate while they received theſe tinges. The ſnake-coloured ſtones ſeem to have received their colour from metallic calces mixed and diffuſed through the ſoft lapideous ſubſtance; and the tranſparent coloured ſtones have probably received their colours from vitriolic ſalts, or from metallic particles diſſolved in the ſame water which ſoftened or liquefied the ſtoney ſubſtance; which metallic ſalts and particles were ſo much diffuſed, that they could not be diſtinctly cryſtallized. That all ſtones have been once liquid and diſſolved in water, appears probable not only from their regular cryſtallized forms, but alſo from the ſolubility of ſome ſtone, as of gypſeous and calcareous earths, in water; and from the water which we know is contained in the harder marbles, as well as in alabaſters; to which water theſe ſtones owe the cryſtallization of their particles.

The veins called cumulated, and the entire metalliferous mountains, are believed by Wallerius to be analogous to the nodules. Theſe metalliferous ſubſtances ſeem to have been originally formed or concreted in the places where they are found.

The metalliferous ſtrata have probably been inſinuated between the lapideous ſtrata, after the ſeparation of theſe from each other by ſome violent cauſe, in [illegible] manner in which we ſuppoſe that the cla[illegible] have been inſinuated between the ſeveral [illegible] ſtone in Derbyſhire. The matters thus [illegible] have been either fluid, which would after[illegible] lize, and form entire regular maſſes; or [illegible] been the ruins of ſhattered ſtrata and veins [illegible] waters, and there depoſited; in which caſe they will appear broken and irregular. The metalliferous ſtrata, although frequently confounded with the horizontal or dilated veins, may be diſtinguiſhed, according to Wallerius, from theſe, by the following properties: 1. They are generally thinner and much broader than the veins called dilated. 2. They are ſeldom found at [illegible] depth than a hundred perches, and generally [illegible] neighbourhood of veins, from which they [illegible] have received their contents. 3. From ſi[illegible] the thin incruſtations called fimbriæ, w[illegible]

quently interpoſed betwixt the rock and the ore or its matrix; and from their want of the other properties of veins.

But in veins, properly ſo called, the ſtrongeſt marks exiſt of ores having been there concreted, and not carried thither and depoſited in their preſent ſtate. Their regular unbroken appearance, their accretion to the contiguous rock, either immediately or by invention of a matrix, the regular appearance of this matrix intervelopingthe ore, the frequent cryſtallization of the ore and of the other contents of the vein, indicate that ores, as well as the other ſolid contents, have been there concreted from a fluid to a ſolid ſtate.

Moſt authors believe, that veins, and the perpendicular cleſts in the ſtony ſtrata of mountains, called fiſſures, have been produced by the ſame cauſe; or rather, they conſider veins only as fiſſures filled with metalliferous matters. They farther believe, that fiſſures have been occaſioned by the exſiccation of ſtrata, while theſe were paſſing from a fluid to a ſolid ſtate. Wallerius thinks, that fiſſures have been formed from exſiccation, but that veins were channels made through the ſtrata, while yet ſoft and fluid, by water, or by the more fluid parts of the ſtrata penetrating and forcing a paſſage through the more ſolid parts. He thinks, that theſe fluid parts conveyed thither their metalliferous and ſtony contents, which were there coagulated or concreted. He ſupports his opinion by obſerving, that all the veins of the ſame ſtratum generally run parallel to each other; that they frequently bend in their courſe; that the ſame vein is ſometimes contracted and ſometimes dilated; that veins are frequently terminated by being ſplit or divided into inferior veins; that veins are frequently wider at bottom than at top, whereas fiſſures are always wideſt at top, and are very narrow below: all which appearances, he thinks, could not have been produced by exſiccation. From theſe reaſons, fiſſures appear to have had a different, and from the diſjunction and rupture of veins croſſed by fiſſures, they ſeem to have had a later origin than veins. Whether fiſſures could have been produced by the very gradual exſiccation of theſe large maſſes or ſtrongly coherent matter; or whether they have been produced by the ſame violent cauſes, namely, earthquakes, by which the ſtrata in which fiſſures are generally found, have been broken and deranged, and by which metalliferous mountains themſelves have been formed, or their ſtrata raiſed above their original level; as ſome others have, with great probability, conjectured; it is not eaſy to determine.

Veins are ſeldom, if ever, found but in mountains; the reaſon of which may not improbably be, that in metalliferous mountains we have acceſs to the more ancient ſtrata of the earth, which in plains are covered with ſo many depoſited, alluvial, and other later ſtrata, that we can ſeldom, if ever, reach the former. That theſe mountains conſiſt of ſtrata which have been originally lower than the upper ſtrata of adjacent plains, appears from an obſervation which has been made, that the ſtrata of mountainous countries dip with more or leſs declivity as they approach the plains, till they gradually ſink under the ſeveral ſtrata of thoſe plains, and are at laſt immerſed beyond the reach of miners. This leading fact in the natural hiſtory of the earth has been obſerved by a ſagacious philoſopher, Mr. Mitchell, in his Conjectures concerning Earthquakes, &c. Philoſ. Tranſ. 1760.

That the inferior ſtrata of the earth contain large quantities of pyritous, ſulphureous, and metalliferous matters, appears, 1. From the ſubterranean fires in thoſe inferior ſtrata, which produce volcanos, and probably earthquakes (as Mr. Mitchell ingeniouſly conjectures). 2. From the obſervation, that all kinds of mountains are not equally metalliferous; but that veins, eſpecially, are only found in thoſe mountains, which, being compoſed of very ancient ſtrata, are called primæval, which form the chains and extenſive ridges on the ſurface of the earth, which direct the courſe of the waters, and which conſiſt of certain ſtrata, the thickneſs of each of which, its generic qualities, and its poſition relatively to the other ſtrata, are, in different parts of the chain of mountains where that ſtratum is found, nearly uniform and alike, notwithſtanding that the numbers, and the inclinations of the ſtrata compoſing contiguous mountains, or even different parts of the ſame mountain, are often very various; and therefore that veins are ſeldom, if ever, found in the mountains called by authors diluvial and temporary, which are ſingle, or detached, which conſiſt not of ſtrata uniformly diſpoſed, but of alluvial maſſes, in which fragments of ores may be ſometimes, but veins never, found. Neverthelefs, ſingle, and ſeemingly detached, mountains in ſmall iſlands have ſometimes been found to be metalliferous. But we muſt obſerve, that theſe mountains conſiſt of uniform ſtrata; that iſlands themſelves, eſpecially ſmall iſlands, may be conſidered as eminent parts of ſubmarine ranges of mountains; and that the mountains of ſuch iſlands may be conſidered as apices or tops only of inferior mountains.

Thoſe mountains are ſaid to be moſt metalliferous which have a gentle aſcent, a moderate height, and a broad baſis, the ſtrata of which are nearly horizontal, and not much broken and diſjoined. In theſe mountains, at leaſt, the veins are leſs interrupted, more extended, and conſequently more valuable to miners, than the veins in lofty, craggy, irregular, and ſhattered mountains.

Authors diſpute concerning the time in which ores have been formed, ſome referring it to the creation of the world, or to the firſt ſubſequent ages; and others believing, that they have been gradually from all times, and are now daily formed. From the accretion of ores and of their matrices to their proper rocks, and from the inſertion of metalliferous nodules and ſtrize in the hardeſt ſtones, we are inclined to believe, that the matter of theſe veins and nodules are nearly coeval with the rocks and ſtones in which they are inveloped. Neverthelefs, we cannot doubt that ſmall quantities, at leaſt, of ores, are ſtill daily formed in veins, fiſſures, and other ſubterraneau cavities. Several well attefted inſtances confirming this opinion are adduced by authors: Cronſtedt mentions an incruſtation of ſilver-ore that was found adhering to a thin coat of lamp-black, or of ſoot, with which the ſmoke of a torch had ſulled a rock in a mine at Koningſberg, in Norway; and that this incruſtation of ſilver-ore had been formed by a metalliferous water paſſing over the rock. Lehmann affirms, that he poſſeſſes ſome ſilver-ore attached to the ſtep of a ladder, found in a mine in Hartz, which had been abandoned two hundred years ago; and that ſeveral ſteps of ladders ſimilarly incruſted had been found. Many other inſtances are mentioned by authors, of galena, pyrites, ſilver-ores, and other metalliferous ſubſtances having been found adhering to wood, to foſſil-coal, to ſtalactitical incruſtations, to muſſel-ſhells, and other recent ſubſtances. From theſe, and from ſimilar inſtances which have occurred there is reaſon to believe, that not only ochres and fragments of ores may, with other alluvial matters, be now daily depoſited, but alſo that ſmall quantities of mineralized ores are recently formed; although many hiſtories mentioned by Becher, Barba, Henckel, and other authors, of the entire renovation of exhauſted veins, and eſpecially thoſe of the growth and vegetation of metals and of ores, appear to be at leaſt doubtful.

Various opinions have been publiſhed concerning the formation of mineralized ores. According to ſome, theſe ores were formed by congelation of the fluid maſſes found in mines, called *fubri*. See GUHR.

Other authors believe, that ores have been formed by the condenſation of certain *mineral*, metallic, ſulphureous, and arſenical vapors, with which they ſuppoſe that mines abound. Some have even affirmed, that they have ſeen this vapour condenſe, and become in a few days changed into gold, ſilver, and other metallic matters. It has been above obſerved, that from ſeveral appearances which occur in veins, there is great reaſon to believe, that ores have not been carried thither and depoſited in their preſent ſtate, but have been there concreted and cryſtallized, that is, changed from a fluid to a ſolid ſtate. But the fluidity of the metalliferous matters at the time of their entrance into veins, may have been occaſioned either by their having been diſſolved in water, if they are capable of ſuch ſolution, or by their having been raiſed in form of vapour by ſubterranean fires. For the diſpoſition to cryſtallize is acquired by every homogeneous ſubſtance that is fluid, whether it has received its fluidity by being melted by fire, or by being diſſolved in a liquid menſtruum, or by being reduced to the ſtate of vapour. Thus cryſtals of ſulphur have been obſerved to be daily formed by the ſulphureous vapours which exhale in the neighbourhood of volcanos. The volubility of the two mineralizing ſubſtances, ſulphur and arſenic, and the power which foſſile bodies poſſeſs of elevating a certain portion of any fixed matter which happens to be united with them, render it probable, that the greateſt part, at leaſt, of mineralized ores have been formed of vapours exhaled from ſubterranean fires, through the cracks in the intervening ſtrata, occaſioned by thoſe earthquakes which have, in a ſingular manner, broke and deranged the ſtrata of metalliferous countries, and which, as has been above remarked, have been probably occaſioned by, at leaſt have certainly been always accompanied with ſubterranean fires.

MINERALS, *Engliſh*. Dr. Woodward has obſerved, that the Engliſh *minerals* are much more valuable and numerous, than has been generally ſuppoſed. Fullers-earth, a thing ſo cheap as to be diſregarded by many, he obſerves, is of almoſt as much value to our commerce, as any article of foreign production. The property this earth has of imbibing oil and greaſe, is not confined to

the trifling ſervice of taking out accidental ſtains in cloaths, but it is of ſo much uſe in cleanſing the wool and the cloth made of it, that we could never have flouriſhed in the cloth-trade in the manner we have done, had we not this foſſil among us ſo very plentiful and cheap, and at the ſame time ſo excellently good. This earth is one inſtance of the pre-eminence of our ſoil above others. Another inſtance we have in our black-lead or wadd, a *mineral* of great uſe and value in ſeveral branches of trade and arts; and which is found no where fine and good, except in England, and in our colonies; and that of the laſt place, though better than the black-lead of other nations, is greatly inferior to our own.

The amber and jet of England are found in conſiderable quantity, and are equal to thoſe of any other part of the world. Our canal-coal comes very near the beauty of jet; and even our common coal for firing is greatly ſuperior in goodneſs, to that of any other part of the world, and is no where found in ſuch vaſt plenty as with us.

The Engliſh earth and gravel are well known to be ſuperior to thoſe of other countries, in none of which ſuch graſs-plats or ſuch gravel-walks are to be ſeen, as in the Engliſh gardens. We have ſtones, ſlates, flags, and other neceſſary foſſils for building, in ſufficient plenty.

Vitriol and alum are found in greater plenty in England, than in any other country; and are ſo eaſily worked or procured from their ores, that we can ſell them cheaper than any other people.

Tin is another article in which England has always had a great pre-eminence; the county of Cornwall alone produces more tin than all the world beſide; and the tin of England is well known to excel that of other nations, as well in value as in quantity.

Lead ore is alſo richer in England than in any other country, and is found in greater quantity here than any where elſe; beſide this, it runs more kindly in the fire, and requires leſs trouble and expence in the working, than any other lead; and is, when wrought, much finer and more ductile than any other lead.

This does not ariſe from any peculiarity in the metal, for lead is the ſame in all countries, when equally purified; but the ſpar which lies about, and is mixed with our lead-ore, is of ſuch a nature and diſpoſition, that it is eaſily wrought upon and readily parts from it, leaving the metal more pure than it can be procured by the common large operations in other countries; ſo that they are forced to ſend it away much leſs pure than our's is.

Copper and iron are alſo found in England in very great plenty, and ſeveral ores of theſe metals have of late been brought into uſe, which were not known before the modern improvements in chemiſtry.

MINERAL, *Æthiops*. See *Æthiops*, and MERCURY.

MINERAL, *turbith*. See TURBITH, and MERCURY.

MINERAL *oil*. See OIL.

MINERALE *bezoardicum*. See BEZOARDICUM.

MINERAL, *cryſtal*. See CRYSTAL *mineral*.

MINERAL *kermes*. See KERMES *mineral*.

MINERAL *waters*, are thoſe, which at their ſpringing forth from under-ground, are found impregnated with ſome *mineral* matter; as ſalt, ſulphur, vitriol, &c. See WATER.

Such are hot baths, ſpaws, purging, &c. ſprings.

MINERAL *waters, earth of*. See EARTH.

MINERAL *juices*. See JUICES.

MINERAL *courts, curia minerales*, in *Law*, courts for regulating the concerns of lead-mines; as *ſtannary courts* are for tin.

MINERALOGY, that previous part of metallurgy, which teaches the ways of finding, judging, and digging of mines.

Mineralogy is an art that requires a conſiderable compaſs of knowlege, before it can be practiſed to advantage; for this art requires a competent ſkill in the nature, effluvia, and effects of mineral matters, whether earths, ſalts, ſulphurs, ſtones, ores, bitumens, gems, or metals: it likewiſe requires a knowlege of the internal ſtructure of the earth, and its various ſtrata, with a competent ſkill in ſubterraneous architecture, menſuration, hydraulics, levelling, and mechanics: without theſe, we can never judge what mountain, plain, or valley, is proper to be dug; in what manner to dig it; how to diſcharge the water that may flow in upon the works; how the beds of ore and ſtone will dip or run; how the various kinds of earths, marble, and other mineral or metallic matters, are to be burſt through or broken; or how the general proceſs of mining ſhould be conducted, in order to procure with the leaſt expence, or bring to open day, the principal matter or ore required. Shaw's Lectures, p. 240.

And, even when all theſe difficulties are conquered, no more than half the work is effected; and the end can ſtill be never obtained, without a tolerable exact knowlege of ſeveral chemical operations, viz. trituration, torrefaction, lotion, calcination, cementation, fuſion, amalgamation, and the like; whence it might be laid down as a rule, that every directing mineraliſt ſhould not only be tolerably verſed in the ſeveral parts of [illegible] philoſophy, but particularly be well acquainted [illegible].

Many mines have been diſcovered by accident. [illegible] firſt laid open a rich vein of the ſilver mine [illegible] in Germany. Sometimes a violent wind, [illegible] trees, or overturning the parts of rocks, [illegible] a mine. The ſame has happened by violent [illegible] earthquakes, thunder, the ſtring of wood [illegible] ſtroke of a plough-ſhare, or a horſe's hoof.

The art of mining does not wait for theſe favourable accidents, but directly goes upon the ſearch and diſcovery of ſuch mineral veins, ores, or lands, as may be worth the working for metal.

The artificial inveſtigation and diſcovery of mines depend upon a particular ſagacity, or acquired habit of judging, from particular ſigns, that metallic matters are contained in certain parts of the earth, not far below its ſurface.

The metallic veins are commonly encompaſſed with a ſort of ſtone peculiar to the mine, and are accompanied with ſeveral ſtrata of different matters, as clay, gravel, rock, &c. Thoſe who work in mines, know by the ſize and colour of the ſtones, when they approach the vein.

They diſcover that there is a mine in a mountain by the marcaſites or mineral ſtones falling from it; by the mineral taſte of the waters; by the quality of the exhalations raiſed from it; and by the difference between the earth over the mines, and that of the neighbouring parts, in the cold time of ſpring and autumn; the froſt lying on the adjacent places, when it thaws about the mines. Add, that the ground's producing but little graſs, and that ſhort, pale, and colourleſs, is an indication of a mine.

Some pretend to diſcover mines by the ſole virtue of the hazle-tree, out of which they form a forked ſtick, called VIRGULA *divinatoria*, which, they ſay, turns of itſelf, in their hands, but differently, according to the different nature of the metals or minerals underneath. This artifice made a great noiſe in France towards the end of the ſeventeenth century; and the corpuſcular philoſophy was called to account for it. But it is now in little credit.

But when no evident ſigns of a mine appear, the ſkillful mineraliſt uſually bores into the earth, in ſuch places as, from ſome analogy of knowledge, gained by experience, (or by obſerving the ſituation, courſe, or nature of other mines) he judges may contain metal.

This method of boring conſiſts in the uſe of a ſet of ſcooping irons, made with joints, ſo as to be lengthened at pleaſure; and thruſt down to a conſiderable depth below the ſurface of the earth, ſo as, when taken out again, to bring back ſamples of the earth, or mineral matter, from the depth whereto the iron deſcended; much after the manner that ſamples of ſugar are taken, by the inſtrument called a reſt, out of the hogſhead.

This method of exploring mines is called by the tinners ſoſſeening, from *eſſus jlean*, i. e. fallen or dropt tin. See SHOAD.

Another method of diſcovering loads of mines is by working DRIFTS acroſs the country, i. e. from north to ſouth, and vice verſâ: and this method is equally cheap and certain. Another very effectual way is by driving an ADIT from the loweſt ground, either north or ſouth, whereby there is a certainty of cutting all loads at twenty, thirty, or forty fathoms deep, if the level admits of it.

After a mine is found, the next thing to be conſidered is whether it may be dug to advantage. In order to determine this, we are duly to weigh the nature of the place, and its ſituation, as to wood, water, carriage, healthineſs, and the like, and compare the reſult with the richneſs of the ore, the charge of DIGGING, STAMPING, WASHING, and SMELTING. This is a matter of œconomical prudence.

A mine is either found in a mountain, a hill, a valley, or a flat; of theſe, mountains and hills are dug with greateſt eaſe and convenience, chiefly becauſe the drains and barrows, that is, the adits and avenues, may be here readily cut both to drain off the water, and to form gangways for bringing out the ore. In whatever place the mine lies we are to look for the veins, which rains or other accidents may have diſcovered; and where ſuch a vein is found, if it be tolerably large and rich, it is beſt to open the mine there. Otherwiſe the moſt commodious place for ſituation is to be choſen, that is, neither on a flat, nor on the tops of mountains, but in their ſides.

The beſt ſituation for a mine, is a mountainous, woody, wholeſome ſpot, of a late eaſy aſcent, and bordering upon a navigable river. For wood is indiſpenſably neceſſary for making the engines and inſtruments, building the huts, fencing in the works, and working the ore. But though wood ſhould be wanting, if a navigable [illegible] be nigh, that may be ſupplied, as water-carriage [illegible]

Water however muſt never be wanting. This is beſt ſupplied by a large river, and is neceſſary on a thouſand occaſions, to waſh the ores, turn the works, &c. Good convenience of carriage muſt alſo be regarded, both for the carrying the ore or metal to market, and the bringing neceſſaries to the workmen: for proviſions are ſeldom to be found where there are mines. See DIGGING, and TRACING.

The places abounding with mines are generally healthy, as ſtanding high, and every way expoſed to the air; yet ſome places, where mines are found, prove poiſonous, and can upon no account be dug, though ever ſo rich. The way of examining a ſuſpected place of this kind, is to make experiments upon brutes, by expoſing them to the effluvia or exhalations, to find the effect.

Mines are compoſed of VEINS, which are oblong tracts, forming maſſes of metals and ores, and lying in the ſtony ſtrata of mountains, &c. Theſe veins are very different in their direction, as well as in length, breadth, and depth. Some are ſtrait, and others curved; ſome are perpendicular to the horizon, and others parallel to it; and the reſt are of the intermediate degrees of declivity. Thoſe which ſtretch obliquely from the ſurface of the earth towards its central parts, are called deep veins; others, that lie ſhallow and circular, ſo as to encompaſs a large ſpace, are called ſpreading veins; others again, whoſe length is inconſiderable in relation to their length and breadth, are called accumulated veins.

The dimenſions, the quality, and the quantity of contents, and many other circumſtances of veins, are alſo very various. Miners diſtinguiſh the ſeveral kinds of veins by names expreſſive of their differences. Thus veins are ſaid to be deep; perpendicular; horizontal, or hanging, or dilated; rich; poor; morning, noon, evening, and night veins, by which their direction towards that point of the compaſs, where the ſun is at any of theſe diviſions of the natural day, is ſignified.

The ſtratum of earth or ſtone lying above a vein is called its roof: and the ſtratum under the vein is called its floor. Some parts of veins are conſiderably thicker than others. Small veins frequently branch out from large veins, and ſometimes theſe branches return into the trunk from which they iſſued. Theſe veins, from which many ſmaller veins depart, have been obſerved to be generally rich.

Veins are terminated variouſly. 1. By a gradual diminution, as if they had been compreſſed, while yet ſoft, by ſuperincumbent weight; or by ſplitting and dividing into ſeveral ſmaller veins: or, 2. they are terminated abruptly, together with their proper ſtrata in which they lie. This abrupt termination of veins and ſtrata is occaſioned by their being croſſed by new ſtrata running tranſverſely to the direction of the former; or by perpendicular fiſſures through the ſtrata; which fiſſures are frequently filled with alluvial matters, or with water, or are empty. Theſe perpendicular fiſſures ſeem to have been occaſioned by ſome rupture or derangement of the ſtratum through which the vein paſſes, by which one part of it has been raiſed or depreſſed, or removed aſide from the other, probably by earthquakes. Where the vein is terminated abruptly it does not ceaſe, but is only broken and diſjoined; and is often recovered by ſearching in the analogous parts of the oppoſite ſide of the deranged ſtratum. A principal part of the art of miners conſiſts in diſcovering the modes of theſe derangements from external marks, that they may know where to ſearch for the diſjoined vein.

The contents of veins are metals and metalliferous mineral kinds, as, the ſeveral ſorts of ores, pyrites, blends, gulure, vitriols; the ſeveral kinds of fluors, ſpars, quartz, hornblend, in which the ores are generally imbedded, or inveloped, and to which therefore the name, matrix of the ore, is applied; ſtalactites; cryſtallizations of theſe metalliferous and ſtony ſubſtances enerufting the ſmall cavities of the circumjacent rock; and laſtly, water, which flows or drops through crevices in that rock.

In a vein, ores are found ſometimes attached to the rock or ſtratum through which the vein runs, but more frequently to a matrix which adheres to the rock; and ſometimes both theſe kinds of adheſion occur in the ſame vein at different places. Frequently betwixt the matrix and the rock is interpoſed a thin cruſt of ſtone or of earth, called by authors the fimbria of the ore.

The matrix or the ſtone in which the ore lies inveloped, is of various kinds in different veins. And ſome kinds of ſtone ſeem better adapted than others to give reception to any ore, or to the ores of particular metals. Thus quartz, ſpar, fluors, and horn-blend give reception to all ores and metals; but ſlates chiefly to copper and ſilver, and never to tin; calcareous and ſparry matrices, to lead, ſilver, and tin; and mica to iron.

Veins lie in ſtrata of different kinds of ſtone; but more frequently in ſome kinds of ſtone than in others. Thus of the ſimple or uncompounded ſtones which compoſe ſtrata, the following are metalliferous: calcareous ſtones; flaty ſand ſtone (ſcot fiſſilis arenoſus Wallerii); feldſpar (ſpatum pyrimachium ſive ſcintillans); quartz; ſometimes jaſper; frequently ſlates; and chiefly micaceous or talky ſtones; and hornblend (lapis corneus Wallerii; bolus indurata particulis ſquamoſis Cronſtedt). No veins have been found in gypſeous or in ſiliceous ſtrata, although cherts and flints frequently contain metallic particles, and ſome inſtances have been obſerved of ores of ſilver and of tin in alabaſter. Of compound ſtones, thoſe are ſaid to be chiefly metalliferous which conſiſt of particles of hornblend. Veins have alſo been found in the red granite; but ſeldom, if ever, in any other granite, or in porphyry. In general, veins are more frequently found in ſoft, fiſſile, and friable ſtrata than in thoſe which are compact and hard.

A vein ſometimes paſſes from one ſtratum into the inferior contiguous ſtratum. Sometimes even the veins of one ſtratum do ſo correſpond with thoſe of an inferior ſtratum, the contiguity of which with the former is interrupted by a maſs of different matter through which the veins do not paſs, that they ſeem originally to have been continued from one ſtratum to the other. Thus in the mines of Derbyſhire, where the veins lie in ſtrata of lime-ſtone, the contiguity of which ſtrata with each other is interrupted in ſome places by a blue marle or clay, and in other places by a compound ſtone called toad-ſtone; the veins of one ſtratum frequently correſpond with the veins of the inferior ſtratum of lime-ſtone, but are never continued through the interpoſed clay or toad-ſtone. But we muſt obſerve, that theſe interpoſed maſſes, the blue marle, clay, and toad-ſtone, have not the uniform thickneſs obſervable in regular ſtrata, but are (eſpecially the toad-ſtone) in ſome places a few feet in depth, and in others ſome hundreds of yards. The above diſpoſition ſeems to indicate, that theſe ſeveral ſtrata of lime-ſtone have been originally contiguous; that the veins now diſjoined have been once continued; that theſe ſtrata of lime-ſtone have been afterwards ſeparated by ſome violent cauſe, probably by the ſame earthquakes which have in a ſingular manner ſhattered the ſtrata of this mountainous country; that the interſtices thus formed between the ſeparated ſtrata have been filled with ſuch matters as the waters could inſinuate, probably with the mixed comminuted ruins of ſhattered ſtrata; or, with the lava of neighbouring volcanos, of which many veſtiges remain.

When a vein of ore is found, and all things prepared for the work, if the vein be of the deep kind, it is firſt to be laid bare, and a pit to be ſunk upon it, at the mouth of which a thed is to be raiſed, and a crane, or barrel and winch fixed, for craning up the ore. The pit is to be ſunk either perpendicular or oblique, as the vein happens to run. It is alſo uſual in this caſe, to cut a burrow or ADIT into the ſide of the hill, which ſhould be twice as high as it is wide, that the workmen may commodiouſly paſs along it with their barrows and burdens: if this ſide pit reaches to the firſt pit, it becomes a true burrow, open at both ends, and renders the work more eaſy and commodious, as the ore may be wheeled out in barrows inſtead of being craned to the mouth of the pit. After the ſame manner, it is uſual to dig many caverns into the ſides of the mountain, in order to ſcoop out the ore; ſo that ſometimes there are thus ſeveral burrows made, to the eaſe and advantage of the work.

The art of DIGGING the veins, varies according to the nature of the vein, or according as it is ſoft or hard. The ſoft vein is generally dug with the ſpade, and turned out into wooden trays, placed underneath to receive it: but the hard veins are knocked out with a gad, or kind of chiſſel and hammer. But, if the ore is ſo hard as to be incapable of breaking in this manner, they uſually ſoften it with fire, which has the power of rendering the hardeſt and moſt flinty ſtones brittle and friable. But a ſtill more expeditious method is the working with gun-powder, by means whereof, much of the hardeſt rock may be ſhivered and ſplit in a very little time; a ſmall parcel of powder being laid in a long hollow cut for that purpoſe, after the nature of a gun-barrel, and fired as it were at a touch hole; a ſmall vent, where the quick match is applied, being left for the purpoſe, and the orifice being otherwiſe hard ſtopped up with clay.

The manner of purſuing and digging all ſorts of veins, the ways of under propping, and diſcharging the water from the works, the ſinking of air ſhafts, curing of damps, and the like, to the beſt advantage, requires more philoſophy than the generality of mere workmen, or the common miners have, though their experience may as much aſſiſt the theoretic philoſopher, as the diſcernment of the latter may that of the former.

The

The neceſſity of cleaving and opening rocks has been always accounted one of the moſt troubleſome articles in the buſineſs of mining; they being often compoſed of ſuch ſtone as tools can work but very ſlowly upon in the common ways. Fire and gunpowder have been the two things principally had a recourſe to on theſe occaſions; and both ſucceeſsfully, but in different ways. The fire calcines ſtones, and they then eaſily become ſhattered to pieces, and give way to tools that would not touch them before; but in this caſe, beſide the expence of wood, the hindrance of the labourers is an article to be conſidered, for the rocks are made ſo hot all about the place where the fire has been, that the people cannot get to work again for a day or two, and then the effect of fire reaches but a little way in the rock.

Gunpowder makes its way much farther, and at the ſame time is much cheaper, and does not delay the work, but the labourers may go on immediately afterwards. There have been many ways contrived of uſing this, but one of the ſimpleſt and beſt, ſeems that delivered by Mr. Beaumont, in the Philoſophical Tranſactions. For this there are only three ſimple inſtruments required, a borier, a gun, and the quinet or wedge. Theſe are the names the miners on Mendip-hills give the inſtruments. The borier is an iron inſtrument, ſteeled at the end; it is two feet two inches long, and is ſomewhat thicker at the ſteeled end than in any other part: the uſe of this is to make the hole in the rock deep enough to receive the powder. The gun is about ſix inches long, and an inch and quarter in diameter; and has a hole drilled through it, to receive the priming. The quinet is a wedge of iron of about ſix inches long, and ſo ſhaped that its flat part on one ſide joins with a flat part in the gun made to receive it, and by that means the gun is faſtened very firmly in its place. Phil. Tranſ. N° 167. p. 854.

The manner of uſing theſe inſtruments, is this: one man holds the borier on the rock, turning it round while another forces its point in by blows of a large hammer on the other end. When the hole is made ſomewhat deeper than the length of the gun, they dry it with a rag, and then put into it two or three ounces of powder; over this they lay a paper, and then they put the gun into the hole, and faſten it in by driving in the quinet or wedge againſt its flat part. When the powder and gun are thus fixed, they paſs down a wire through the hole drilled in the gun, and with this they pierce a hole through the paper which covers the powder; they then prime the gun, and lay a train with a lighted match; but all go out of the mine before the gunpowder takes fire, and as ſoon as it has gone off, they go down to work again, finding the rock ſplit and the inſtruments unhurt. The paper in this caſe is put over the powder only that the tools may be ſafely employed in driving down the gun and the quinet, becauſe were not the powder covered it might do miſchief to the workmen, by going off by ſome ſpark cauſed by ſtriking either againſt thoſe inſtruments, or againſt the rock itſelf.

MINERVA, in *Mythology*, derived according to ſome *à minis*, from the threats of her ſtern countenance, otherwiſe called *Pallas*, is the goddeſs of wiſdom and the arts; and the only one of the offspring of Jupiter to whom pertain the prerogatives of the ſupreme rank of divinity. *Minerva* is repreſented both by the painters and poets of antiquity, as a beauty of the ſeverer kind: the diſtinguiſhing character of her face is dignity and a certain fierceneſs, which has more of maſculine than feminine in it: and, therefore, more apt to ſtrike one with awe and terror, than to charm one, at firſt ſight. Her dreſs and attributes are adapted to the characters of her face; ſhe moſt uſually appeared with a helmet on her head, and a plume that nodded formidably in the air; in her right hand ſhe ſhook her ſpear, and in the other graſped her ſhield, with the head of the dying MEDUSA upon it; the ſame figure appears alſo on her breaſt-plate; and ſometimes the goddeſs herſelf is repreſented as having living ſerpents about her breaſts, and about her ſhoulders; ſhe is alſo accompanied with a cock, which is a fighting bird, and correſponding to her character as the inventreſs and preſident of war, and an owl, which ſees in the dark, and, therefore, is the image of wiſdom. It is probable that the Romans conſidered JUPITER, JUNO, and *Minerva*, as one and the ſame divinity, under three different names: among which names, that of Jupiter might ſignify ſupreme goodneſs; that of *Minerva*, ſupreme wiſdom; and that of Juno, ſupreme power: thus the learned Dr. Cudworth obſerves, Intell. Syſt. b. 1. c. 4. p. 450. that the three Capitoline gods, Jupiter, Juno, and *Minerva*, may be underſtood to have been nothing elſe but ſeveral names and notions of one ſupreme deity, according to its ſeveral attributes and manifeſtations.

MINERVALIA, among the Romans, called alſo *Quinquatria*, were feaſts celebrated in honour of Minerva. One of theſe feaſts commenced on the 3d of January, and another on March 19th, and laſted five days. The firſt day was ſpent in prayers to the goddeſs; the next in offering ſacrifice, ſeeing gladiators fight, acting tragedies upon mount Albanus, and reciting pieces of wit, to which the conqueror had a prize given him. Scholars had a vacation, and made a preſent to their maſters, which was called *Minervale*.

MINIATURE, or MINIATURE, a delicate [illegible] ing, conſiſting of little points or dots, inſtead of [illegible] uſually done on vellum, ivory, or paper, with very little or ſimply water-colours.

The word comes from the Latin *minium*, [illegible] being a colour much uſed in this kind of painting. The French frequently call it *mignature*, from *mignon*, *fine*, *pretty*, on account of its ſmalneſs and delicacy; and this may be ultimately derived from *minor*, *ſmall*.

Miniature is diſtinguiſhed from other kinds of painting by the ſmalneſs and delicacy of its figures, the neatneſs of their colours, and fainteneſs of the colouring; and on this account it requires to be viewed very near.

Thoſe colours that have the leaſt body are the beſt and moſt commodious for painting in *miniature*; ſuch are carmine, ultramarine, fine lakes, and green made of the juices of ſeveral kinds of herbs and flowers.

The colours commonly uſed in *miniature* painting are for *red*, carmine, lake, roſe-pink, vermilion, red lead, ſcarlet-oker, common Indian red, red oker, Venetian red, and Spaniſh brown: for *blue*, ultramarine, ultramarine aſhes, Pruſſian blue, verditer, indigo, ſmalt, blue bice, and litmus: for *yellow*, gamboge, Naples yellow, Dutch pink, Engliſh pink, gall-ſtone, maſticot, French berry waſh, turmeric waſh, zedoary waſh, and tincture of ſaffron: for *green*, ſap-green, verdigriſe, diſtilled verdigriſe, and terra verte: for *purple*, true Indian red, archal, and logwood waſh: for *brown*, biſtre, umber, brown oker, Cologn earth, and terra Japonica: for *white*, flake white, white lead, calcined hartſhorn, pearl white, Troy white, lake white, and egg-ſhell white: and for *black*, Indian ink, lamp black, ivory-black, and blue black.

Painting in *miniature* is the niceſt and moſt tedious of all others; being performed wholly with the point of the pencil.

There are ſome painters who never uſe any white colour in *miniature*, but make the ground of the vellum ſerve to raiſe their figures; in which caſe, the lights appear bright in proportion to the depth and ſtrength of the colours of the figures. Others before they go to work, give the vellum a light waſh with white lead, well prepared and purified.

When paper of any proper kind is uſed, it is ſufficient to prime it with iſinglaſs ſize, thickened properly with pearl white, and any pigment which will give the ground the deſired colour. But common paper may be rendered ſtronger and fitter for receiving the colours, by laying on the back of it a coat of ſtarch, boiled with water to a moderate conſiſtence, and rendered more tenacious by the addition of a little iſinglaſs. This ſhould be laid on very ſmoothly with a bruſh, and the paper, when nearly dry, muſt be put betwixt two leaves of a book, or betwixt two ſheets of paper and two boards, and compreſſed by a weight laid upon them. Two ſheets of paper cemented together by the ſtarch and iſinglaſs, and treated in the ſame manner, make a very commodious ſubſtance for painting in *miniature*. Vellum requires only to be ſtrained on a paſteboard, and primed in the ſame manner; and if it ſhould be greaſy, rubbed over with the gall of any beaſt.

When the colours are laid on flat without dotting, though the figures be ſmall, and the ground either vellum or paper, it is not called *miniature*, but *waſhing*.

The colours for *miniature* may be mixed up with a ſolution of gum Arabic, or gum tragacanth, in water, or with iſinglaſs ſize. For the method of preparing ivory for *miniature*, ſee IVORY.

MINICULATOR, among the Romans, a ſervant who embelliſhed any writing with MINIUM.

MINIM, in *Muſic*, a note, or character of time; equal to two crotchets, or half a ſemibreve.

The invention of the *minim* is aſcribed to a certain prieſt in Navarre, but the firſt who uſed it was Philip de Viſtriaco, in whoſe time it was the ſmalleſt note in practice. See TIME and CHARACTERS *of muſic*.

MINIM, *ſextuple of the*. See SEXTUPLE.

MINIMA *naturæ*, or MINIMA *naturalia*, among *Philoſophers*, the primary articles, whereof bodies conſiſt; the ſame with what are otherwiſe called CORPUSCLES, and ATOMS.

MINIMA, in the *Higher Geometry*, the ſmalleſt quantities attainable in any given caſe. See MAXIMUM.

MINIMA, *per*. See PER *minima*.

MINIMENTS, or MUNIMENTS. See MUNIMENTS.

MINIMI *digiti extensor*. See EXTENSOR.

MINIMI *digiti pedis abductor*. See ABDUCTOR.

MINIMS, MINIMI, an order of religious, inſtituted about the year 1440, by S. Francis de Paulo, confirmed in 1473, by Sixtus IV. and by Julius II. in 1507. See BONHOMMES.

Theſe have improved on the humility of the MINORS, by terming themſelves *Minimi* or *Minims*, q. d. leaſt, or ſmalleſt.

MINIMUS *glutæus*. See GLUTÆUS.

MINION, a ſort of CANNON, or piece of ORDNANCE, whereof there were formerly two kinds; large, and ordinary, anſwering to our ſix-pounders. See GUN.

MINISTER, one that ſerves or conducts the public worſhip of God.

In the reformed church, prieſts, or thoſe ordained to preach, and do the other functions of the prieſthood, are called abſolutely and ſimply *miniſters*.

In which ſenſe, biſhops, &c. are ſaid to be *miniſters* of God; *miniſters* of the word, of the goſpel, &c. In ſome churches they are alſo called *paſtors*.

MINISTERS *of the altar* are properly thoſe who attend, and aſſiſt the prieſt at the adminiſtration of the euchariſt. See DEACON, and SUBDEACON.

Officers of ſtate, &c. are called the king's *miniſters*; as adminiſtering the affairs of juſtice, policy, &c. for him.

MINISTER *of ſtate*, is he with whom a prince entruſts the adminiſtration of his government; or to whom he commits the care and direction of the principal affairs thereof.

Boethius is propoſed as a model for *miniſters* of ſtate. The grand vizier is the prime *miniſter* of the Ottoman empire.

MINISTERS, *foreign*, or the *miniſters of foreign princes*, are their embaſſadors, envoys, agents, or reſidents in the courts of other princes.

There are two kinds of foreign *miniſters*. *Miniſters* of the firſt rank, who are alſo called EMBASSADORS, and *envoys extraordinary*.

And *miniſters* of the ſecond rank, who are the ordinary reſidents.

Thoſe of the firſt rank have a repreſentative character, which the others have not; though theſe laſt are ſometimes inveſted with fuller powers than the former.

MINISTER is alſo the title which certain religious orders give to their ſuperior.

In this ſenſe we ſay, the *miniſter* of the Mathurins, or Trinitarians.

MINISTER, among the *Jeſuits*, is the ſecond ſuperior of each houſe; thus called, as being an aſſiſtant to the ſuperior, or rector.

The general of the Cordeliers order is alſo called the *miniſter general*. See JESUITS.

MINISTRY, or MINISTERY, a profeſſion, office, or employment, which a perſon diſcharges for the ſervice of God, the public, or ſome particular perſon.

In which ſenſe we ſay, a biſhop muſt give account to God of his *miniſtry*, &c.

MINISTRY is alſo uſed for the government of a ſtate, by ſome great miniſter, under the ſovereign authority.

In which ſenſe we ſay, the *miniſtry* of the cardinal de Richelieu, &c.

MINISTRY is alſo frequently uſed as a collective word, ſignifying the miniſters or officers of ſtate.

Thus we ſay, the *miniſtry* oppoſed a thing; meaning, the miniſters oppoſed it.

MINIUM, in the *Natural Hiſtory of the Ancients*, a name given to what we now call CINNABAR, or native mineral of a ſhining red colour, out of which quickſilver was extracted. This native mineral becoming much in uſe was ſoon adulterated; and that commonly with lead-ore calcined to a rednels; and hence, after the two words *minium* and *cinnabar* had been long uſed in common, the cinnabar became retained only to the native mineral, and the *minium* to that adulterated with lead-ore, or to the red adulterating matter alone, which is the ſenſe in which it is ſtill uſed.

Minium, or *red* LEAD, is a CALX of lead of a vivid yellowiſh red colour, which colour it acquires by a ſlow calcination and reverberation. The *minium* in commerce is chiefly brought from Holland, where large quantities of it are manufactured.

The method in which *minium* is made in large quantities with us, is this: they firſt burn lead in a furnace into a kind of litharge, by continually ſtirring it while melted with an iron rake; this they afterwards grind with two pair of ſtones, which deliver it from one to another, the firſt pair grinding it coarſer, the ſecond finer; theſe are worked by means of a mill which moves ſix pair of them at once. When thus reduced to a fine powder, it is waſhed and then put into a furnace, and is burnt with a reverberatory fire for two or three days, all the while they continue ſtirring it with a large iron rake, hung on a ſwivel or iron hook; and toward the end of the time they watch its being of the right colour. When this is doing, the fire muſt not be carried beyond a certain degree, leſt the matter clod and run together.

The proceſs by which *minium* is prepared is deſcribed in the following manner by M. Jars. The furnace is of the reverberatory kind, with two fire-places at the ends; each fire-place being ſeparated from the area, or body of the furnace, by a wall twelve inches high. The fire-places are fifteen inches broad, and their length is equal to the breadth of the whole furnace, which is about eight or nine feet. The length of the area from one place to the other is nine or ten feet. The quantity of lead uſed in one operation is about 1500 pounds, of which nine parts are lead obtained from furnaces where the ore is ſmelted, and one part is lead extracted from the ſcoria which is formed in ſmelting the ore. This latter kind is ſaid to be neceſſary, as the former could not alone be reduced into powder. All the lead is at once put into the area, the bottom of which is level. The calx, as faſt as it is formed, is drawn to one ſide, by means of a rake ſuſpended by a chain before the mouth of the furnace. In four or five hours the whole quantity of the lead is calcined, or, if any pieces remain uncalcined, they are ſeparated, and kept for the next operation. The heat employed is that of a cherry-red, and the fire-places and mouth are kept open, that the air may accelerate the calcination. The powder or calx is to be frequently ſtirred to prevent its concreting, and when this operation has been continued about twenty-four hours, the matter is taken out of the furnace, and laid on a flat pavement. Then cold water is thrown on it, to give it weight, as the workmen ſay, but rather (as M. Jars thinks) to make it friable. It is then to be ground in a mill, and the finer part is ſeparated by waſhing, while the coarſer part, reſerved for ſome following operation, is to be placed at the mouth of the furnace in order to retain the melted lead. The fine powder, which is now of a yellow colour, is again put into the fame or a ſimilar furnace, and expoſed to a very moderate fire, from thirty-ſix to forty-eight hours; during which time, it is ſtirred frequently to prevent its concreting; and the powder gradually acquires its proper red colour. The *minium* is then to be taken out of the furnace, cooled, and ſifted through an iron ſieve placed in a caſk. Mem. de l'Academie Royal à Paris, 1770. See CALCINATION.

MINIUM, in *Medicine*, is uſed externally; it obtunds the acrimony of the humours, allays inflammations, and is excellent in the cleanſing and healing of old ulcers: it is uſed, on theſe occaſions, in many of the plaſters and ointments of the ſhops; it is an ingredient in the officinal compoſition, called *emplaſtrum de minio*, uſed as a deſiccative and cicatrizer: though more rarely than that made in the ſame manner with litharge, becauſe it does not ſtick ſo well, and is more difficult of preparation.

It was with *minium* the ancient Romans and Grecian ladies tinged their nails and faces of a red colour. For, as to our modern paints, without doubt they were not known in thoſe days.

The bright orange colour of *minium* might render it valuable in painting, if it could ſtand with certainty in either oil or water. But as it is ſubject to become black, it cannot be ſafely truſted, except in hard varniſhes: and is, therefore, ſeldom uſed in oil, or even in water, unleſs for very groſs purpoſes, or as a ground for vermilion.

The goodneſs of *minium* may be diſtinguiſhed by the brightneſs of its colour: and the adulteration to which it is liable, may be detected, by putting an ounce of it into a crucible with an equal quantity of charcoal duſt, well mixed together, and placing the crucible in a common fire ſufficient to melt lead, which is to be covered with another ſmall crucible inverted into it. When it has been continued for ſome time on the fire, take it out and ſtrike it againſt the ground. The *minium* will thus be reduced to its metallic ſtate; and its diminiſhed weight, when freed from the charcoal duſt and cold, will indicate the proportion of adulterated matter. *Minium* is alſo uſed as a FLUX in forming the ENAMEL for grounds, and in GLAZING, &c.

MINNIN, a ſtringed inſtrument of muſic among the ancient Hebrews, having three or four chords to it. See Kircher's figure of it, *Tab. Muſic. fig.* 6. Though there is reaſon to queſtion the antiquity of this inſtrument; both becauſe it requires a hair-bow, which was a kind of *plectrum* not known to the ancients, and becauſe it ſo much reſembles the modern viol. Kircher took the figures of this, the *nachal*, *chinnor*, and *plalterj*, from an old book in the Vatican library. Hawkins's Hiſt. Muſic, vol. i. p. 255.

MINOR, a Latin term, literally denoting *leſs*; uſed in oppoſition to *major*, greater.

Thus we say, St. James's *minor*; Asia *minor*; the *minor* excommunication, &c.

MINOR *ædilis*. See ÆDILES.

MINOR *anticus serratus*. See SERRATUS.

MINOR *barons*. See BARON.

MINOR, *canis*. See CANIS.

MINOR *gastricus*. See GASTRIC.

MINOR *oculi obliquus*. See OBLIQUUS.

MINOR *ordo*. See ORDERS.

MINOR, *rectus*. See RECTUS.

MINOR, *teres*. See TERES.

MINOR, *ursa*. See URSA.

MINOR, in *Law*, denotes a perſon under age, or who, by the laws of the country, is not yet arrived at the power of adminiſtring his own affairs, or the poſſeſſion of his eſtate.

Among us, a perſon is a *minor* till the age of twenty-one: before which time his acts are invalid. See AGE, and INFANT.

It is a maxim in the common law, that in the KING there is no *minority*, and therefore he hath no legal guardian; and his royal grants and aſſents to acts of parliament are good, though he has not in his natural capacity attained the legal age of twenty-one.

The *minority* of the kings of Sweden, Denmark, and the provinces of the empire, terminates at eighteen years; and that of the kings of France at fourteen, by an ordonnance of Charles V. in 1374.

It is alſo provided by the cuſtom and law of PARLIAMENT, that no one ſhall ſit or vote in either houſe, unleſs he be twenty-one years of age. This is likewiſe expreſly declared by ſtat. 7 and 8 Will. III. cap. 25. with regard to the houſe of commons.

MINOR, in *Logic*, is the ſecond propoſition of a formal or regular SYLLOGISM, called alſo the ASSUMPTION.

MINOR, in *Muſic*, is applied to certain concords, which differ from, or are lower than, others of the ſame denomination by a leſſer ſemitone, or four commas.

Thus we ſay, a third *minor*, or leſſer third: or a ſixth major and *minor*.

Concords that admit of major and *minor*, i. e. greater and leſs, are ſaid to be *imperfect* CONCORDS.

MINORESSES. See *St.* CLARE.

MINORS, or *Friers* MINORS, an appellation which the FRANCISCANS aſſume, out of ſhew of humility; calling themſelves *freares minores*, i. e. *leſſer brothers*; and ſometimes *Minorites*.

There is alſo an order of regular *Minors* at Naples, which was eſtabliſhed in the year 1588, and confirmed by Sixtus V.

MINORATIO, a word uſed by the ancients to expreſs a ſlight or moderate evacuation, only ſerving to leſſen the humours, not to carry them off.

MINOS, in *Mythology*, one of the three judges of hell, of a rank ſuperior to the other two, viz. Æacus and Rhadamanthus. Homer repreſents him as ſitting with a ſceptre in his hand, in the midſt of the ghoſts of departed mortals, who plead their reſpective cauſes in his preſence. Virg. *Æn.* 6. v. 432. places an urn by him, containing the ſeveral lots of mankind. The particular diſtrict of Ades, over which he was ſuppoſed to preſide, was EREBUS: and it was his office to determine the character and final condition of the ſpirits cited to his tribunal. *Minos*, it is ſaid, was the firſt king of Crete, and conſidered as the wiſeſt legiſlator of antiquity; on which account he obtained the honour of being judge in the inviſible world. This *Minos*, whoſe inſtitutes are ſaid to have ſerved as a model for thoſe of Lycurgus, flouriſhed, according to Selden, one thouſand four hundred and ſixty-two years, but, according to the abbé Banier, only one thouſand three hundred and twenty years before Chriſt.

MINOTAUR, MINOTAURUS, in *Antiquity*, a fabulous monſter, much talked of by the poets; feigned to be half man, and half bull.

The *Minotaur* was brought forth by Paſiphae, wife of Minos II. king of Crete. It was ſhut up in the labyrinth of that iſland; and at laſt was killed by Theſeus.

Servius gives us the explication of this fable. He ſays that a ſecretary of king Minos, named Taurus, *bull*, had an intrigue with the queen Paſiphae, in the chamber of Dædalus; and that ſhe was at length delivered of twins, one of which reſembled Minos, and the other Taurus. This occaſioned the production to be reputed monſtrous.

MINOVERY, formed of the French *main-auvre*, q. d. *handy-work*, a treſpaſs committed in the FOREST, by ſomething that is a man's handy-work; as an engine to catch deer, &c.

MINOW, or MINIM, in *Ichthyology*, a name given by the Engliſh to the ſmall fiſh, called by authors the phoxinus. According to the new Artedian ſyſtem, this is a ſpecies of the CYPRINUS; and the *cyprinus phoxinus* of Linnæus, with the dorſal fin, conſiſting of eight rays, a brown ſpot on the tail, and a pellucid body. The lateral line of this fiſh is of a golden colour; the back flat, and of a deep olive; the ſides and belly vary much in different fiſh; in a few they are of a rich crimſon, in others bluiſh, and in others white; the body is ſlender and ſmooth, the ſcales being extremely ſmall; the tail is forked, and marked near the baſe with a duſky ſpot; the whole length ſeldom exceeds three inches. The *minow* is found in ſhoals in many of our ſmall gravelly ſtreams. Pennant.

MINSTER, Saxon, *mynſter*, or *myndſter*, anciently ſignified the church of a monaſtery, or convent.

MINSTREL, an ancient term for a fidler, or player on any other kind of muſical inſtrument.

Borel derives the word from *manus* and *hiſtrio*, one who diverts with the hand; or from *minor hiſtrio*, *little buffoon*: Du Cange from *miniſtellus*, a diminutive of *miniſter*, becauſe the *minſtrels* were anciently ranked among the lower officers, miniſters, or ſervants.

According to Dr. Percy in his Eſſay on the Ancient Engliſh *Minſtrels*, the word is derived from the French *menestrier*; and was not in uſe here before the Norman conqueſt: and it is remarkable, that our old monkiſh hiſtorians do not uſe the word *citharœdus*, *cantator*, or the like, to expreſs a *minſtrel* in Latin; but either *mimus*, *hiſtrio*, *joculator*, or ſome other word that implies geſture. Hence it ſhould ſeem that the *minſtrels* ſet off their ſinging by mimickry or action; or according to Dr. Brown's hypotheſis, united the powers of melody, poem, and dance. Theſe *minſtrels* were probably the genuine ſucceſſors of the ancient bards, who joined the arts of poetry and muſic, and ſung verſes to the harp of their own compoſing. After the converſion of the Saxons to Chriſtianity, the poets and *minſtrels* became two ſeparate profeſſions: and the latter continued to be a diſtinct order of men, and got their livelihood by ſinging verſes to the harp, at the houſes of the great: where they were hoſpitably and reſpectfully received, retaining many of the honours ſhewn to their predeceſſors the Bards and Scalds. And though ſome of them only recited the compoſitions of others, many of them ſtill compoſed ſongs themſelves, and all of them could probably invent a few ſtanzas on occaſion. There are two remarkable facts in hiſtory, which prove that the profeſſion of a *minſtrel* was held in great reverence among the Saxon tribes, as well as among their Daniſh brethren. In the year 878, when king Alfred wiſhed to learn the true ſituation of the Daniſh army, which had invaded his realm, he aſſumed the dreſs and character of a *minſtrel*, *fingens ſe joculatorem*, *aſſumpta citharâ*, &c. and under this character, though he could not but be known to be a Saxon, obtained an honourable reception. About ſixty years after, a Daniſh king made uſe of the ſame diſguiſe to explore the camp of our king Athelſtan. The *minſtrel* was, therefore, a privileged character with both theſe people: and ſo late as the reign of Edw. II. the *minſtrels* were eaſily admitted into the royal preſence; an inſtance of which is mentioned by Stow, Survey of Lond. 1703, p. 469. In the fourth year of Richard II. John of Gaunt erected at Tutbury, in Staffordſhire, a court of *minſtrels*, with full power to receive ſuit and ſervice from the men of this profeſſion within five neighbouring counties, to enact laws and determine their controverſies, &c. for which they had a charter. See Plot's Hiſt. Staff. p. 435, &c. The *minſtrels* continued down to the reign of Elizabeth; in whoſe time, however, they had loſt much of their dignity, and were ſinking into contempt and neglect; yet ſtill they ſuſtained a character far ſuperior to any thing we can conceive at preſent of old ballads. Towards the end of the ſixteenth century this claſs of men loſt all credit, and were ſunk ſo low in the public opinion, that in the thirty-ninth year of Elizabeth, a ſtatute was paſſed, by which *minſtrels*, wandering abroad, were included among rogues, vagabonds, and ſturdy beggars, and were adjudged to be puniſhed as ſuch. This act ſeems to have put an end to the profeſſion, for after this time they are no longer mentioned. Judge Blackſtone obſerves, that in ſome manors, the copyholders were bound to perform many ſervile offices for the lord, who found them meat and drink, and ſometimes, (as is ſtill the uſe in the highlands of Scotland) a *minſtrel* or piper for their diverſion. Comm. b. ii. p. 96.

MINT, the place where the king's money is coined.

Anciently there were *mints* in moſt cities of England. The chief *mint*, at preſent, is the Tower of London.

MINT, *officers of the*, are, 1. The *warden*, who is the chief, and is to receive the the bullion, and overſee all the other officers. This officer has, for himſelf and a clerk, 450*l.* a year. 2. The *maſter-worker*, with an annual ſalary for himſelf and three clerks, of 650*l.* who receives the bullion from the warden, cauſes it to be melted, and delivered to the moniers; and takes it from them [illegible]

when coined. 3. *Comptroller*, with a falary, for himſelf and clerk, of 350*l.* a year, who is to ſee, that the money be made to the juſt aſſize, and to overſee the officers. 4. The *aſſay-maſter*, who weighs the ſilver and gold, and ſees whether it be STANDARD. See REMEDY. This officer has, for himſelf and clerk, 225*l.* a-year. 5. The two *auditors*, who take all the accounts. 6. The *ſurveyor of the melting*, who is to ſee the ſilver caſt out, and that it be not altered after it is delivered to the melter, i. e. after the aſſay-maſter has made a trial of it. 7. The *clerk of the irons*, who is to ſee that the irons be clean, and fit to work with. Theſe two offices are united in one perſon, who has, for himſelf and clerk, 132*l.* 10*s.* a year, and alſo a deputy. 8. The *chief engraver*, who engraves the dies and ſtamps, for the coinage of money, who has a ſalary of 200*l.* a year: there is alſo a *ſecond engraver*, with 80*l.* a year, and aſſiſtant. 9. The *melters*, who melt the bullion before it comes to coining. 10. The *blanchers*, who anneal, or boil and cleanſe the money. 11. The *porter* and *aſſiſtkeeper*, who keep the gate, &c. of the *mint*. 12. The *provoſt* of the *mint*, at 100*l.* a-year, who provides for all the moniers, and overſees them. And, laſtly, the *company of moniers*, each of whom has 40*l.* a-year; ſome of which ſhear the money, ſome forge it, ſome ſtamp or coin it, and ſome round and mill it. To this office, there are alſo the *weigher* and *teller*, who, for himſelf and clerk, has a ſalary of 142*l.* 10*s.* a year; his deputy; king's clerk and clerk of the paper, with 100*l.* a year, and his deputy; *ſurveyor of the money-preſſes*, at 40*l.* a year; *ſolicitor*, at 60*l.* a year; warden's deputy, maſter's deputy, comptroller's deputy, and ſubordinate clerks. See COINAGE.

MINT was alſo a pretended place of privilege, in Southwark, near the King's Bench, put down by ſtatute. If any perſons, within the limits of the *Mint*, ſhall obſtruct any officer in the ſerving of any writ or proceſs, &c. or aſſault any perſon therein, ſo as he receive any bodily hurt, the offender ſhall be guilty of felony, and be tranſported to the plantations &c. Stat. 9 Geo. I.

MINT, *mentha*, in *Botany*, a genus of the *didynamia gymnoſpermia* claſs. Its characters are theſe: it has a lip-flower of one petal; the mouth is cut into four almoſt equal ſegments, the upper being a little larger and indented; it has four erect ſtamina, the two neareſt being the longeſt; in the bottom of the tube is ſituated a four-pointed germen, which turns to four naked ſeeds, ſitting in the empalement. Miller enumerates eighteen and Linnæus ſixteen ſpecies.

All the ſorts of *mint*, of which we have ſeveral propagated in gardens for medicinal uſe, are to be propagated by parting the roots in ſpring, or planting cuttings in any of the ſummer months, but they muſt have a moiſt ſoil; and if the weather proves dry, they will require very frequent waterings, after they are firſt planted. They ſhould be planted in beds of four feet width, with walks two feet wide between them, and ſhould be ſet at five inches diſtance. And they ſpread ſo faſt at the roots that the beds ſhould never ſtand above three years before they are taken up and tranſplanted; for the roots after this time will mat and clog together, ſo as to choak one another.

Many people are fond of *mint*-ſallad early in the ſpring; the way to propagate this, is to take up ſome roots of *mint* before Chriſtmas, and plant them pretty cloſe upon a moderate hot bed, covering them an inch deep with freſh earth; the beds muſt then be covered either with mats, or frames and glaſſes, and in a month's time the *mint* will come up and will ſoon be fit for uſe.

When *mint* is cut for drying, it ſhould be done juſt when it is in flower, and muſt always be done in a dry day; for if cut in wet weather, the leaves will change black. It ſhould then be tied in ſmall bunches, and hung in a ſhady place upon lines.

If the ſoil be good, *mint* will afford three crops every ſpring; but after July, they ſeldom are ſo good, ſo that the ſhoots made after that time ſhould be ſuffered to remain till the end of September, to be cut for drying. After this cutting there ſhould be about an inch of freſh earth ſifted over them, which will make them ſhoot much better the following ſpring. Miller.

No plant grows ſo vigorouſly and readily in water as *mint*; and therefore none is ſo proper for trying experiments in vegetation.

Spear-mint is a name commonly given to the narrow-leaved ſpiked *mint*; this herb has a ſtrong, agreeable, aromatic ſmell, and a bitteriſh, roughiſh, moderately warm taſte. It is in general uſe as a reſtringent, ſtomachic, and carminative; in vomitings and weakneſs of the ſtomach, there are, perhaps, few ſimples of equal efficacy. The leaves are ſometimes taken in ſubſtance, beaten with thrice their weight of fine ſugar into a conferve. By diſtillation, a pound and a half of the dry leaves communicate a ſtrong impregnation to a gallon of water, yielding the common ſimple *mint*-water of the ſhops; which is occaſionally made ſtill richer in the virtue of the *mint*, by ſteeping in it, for three or four hours, in a warm place, a freſh quantity of the herb, as half an ounce to a pint: the diſtilled water proves rather more elegant if drawn from the freſh than from the dry plant. Along with the aqueous fluid an eſſential oil diſtils, called the eſſential oil of *mint*, of a pale yellowiſh colour, changing by age to a reddiſh, and at length to a dark red; in quantity near an ounce from ten pounds of the freſh herb in flower, ſmelling and taſting ſtrongly of the *mint*, but ſomewhat leſs agreeable than the herb itſelf. The officinal ſpirituous water of *mint* is prepared by drawing off a gallon of proof ſpirit from a pound and a half of the dried leaves, which will be ſtrongly impregnated with *mint*.

The *water-mint*, with leaves ſomewhat oval ſet on pedicles and long ſtamina ſtanding out from the flowers, and the *hairy water-mint*, with long hairy leaves, having no pedicles, and broad ſpikes of flowers, grow wild in moiſt meadows, marſhes, and on the brinks of rivers, and flower towards the end of ſummer. Theſe are leſs agreeable in ſmell than the *ſpear-mint*, and in taſte bitterer and more pungent. They yield a much ſmaller proportion of eſſential oil; but partake of the virtues of *ſpear-mint*, in an inferior degree. The *hairy water-mint* is ſuppoſed to be the *auricularia* or ear-wort, celebrated by Marloe for the cure of deafneſs; though probably not more effectual againſt that complaint than the other *water-mint* againſt nephritic ones, in which it is ſaid to have been formerly an empirical ſecret.

Pepper-mint is a ſpecies of *mint* with acuminated leaves, on very ſhort pedicles, and the flowers ſet in ſhort thick ſpikes or heads. It is a native of this kingdom, and raiſed plentifully in gardens, for medicinal purpoſes.—This ſpecies has a more penetrating ſmell than any of the other *mints*; and a much ſtronger and warmer taſte. It is a medicine of great importance in ſtubborn colics, hyſteric depreſſions, and other ſimilar complaints. In diſtillation with water, it yields a conſiderable quantity of eſſential oil, of a pale greeniſh yellow colour, which becomes darker coloured by age, very light, ſubtile, and poſſeſſing in a high degree the ſpecific ſmell and penetrating pungency of the *pepper-mint*. A ſimple and a ſpirituous diſtilled water, drawn in the ſame proportions as thoſe of *ſpear-mint*, and the eſſential oil, are kept in the ſhops. Lewis's Mat. Med.

MINT, *corymbiferous*, in *Botany*, a name given by ſome to a ſpecies of TANSY.

MINT, *cat's*, the Engliſh name of a genus of plants, called by botanical writers *cataria*. See CATMINT.

MINTERS, or MONIERS. See MONEYERS and MINT.

MINTING is ſometimes uſed for the COINING of money.

MINUARTIA, in *Botany*, a genus of the *triandria trigynia* claſs. Its characters are, that it has a five-leaved calyx, no corolla, and the fruit is a ſingle-celled three-valved capſule containing ſeeds. There are three ſpecies.

MINUET, or MENUET, in *Muſic*, a compoſition anſwering to a kind of dance of the ſame name, ſaid to be invented in Poictou; the motion whereof is triple, with three crotchets in a bar $\frac{3}{4}$, though it is commonly perſormed in the time $\frac{3}{2}$. It has commonly two ſtrains, each played twice over; the firſt has four or eight bars; the laſt note of which ſhould be either the *dominant* or *mediant* of the mode, never the final; and the ſecond has eight bars, it uſually ends on the final of the mode, with a pointed minim or whole bar.

The word is ſaid to be derived from the French *menu*, *little*, and ſignifying a ſmall pace.

MINUS, in *Algebra*. See CHARACTERS in *Arithmetic*.

MINUS, *quo*, in *Law*. See QUO *minus*.

MINUSCULÆ, in *Printing*, denote the ſmall or running letters; as contradiſtinguiſhed from *majuſculæ*, or capitals.

MINUTE, from the Latin *minutus*, *ſmall*, in *Geography* and *Aſtronomy*, is the ſixtieth part of a degree.

In which ſenſe *minute* is alſo called *prime*, or *prime-minute*.

The diviſions of degrees are fractions, whoſe denominators increaſe in a ſexageſcuple ratio; that is, a *minute* or prime is $= \frac{1}{60}$; a ſecond, or ſecond *minute*, $= \frac{1}{3600}$, &c.

In aſtronomical tables, &c. *minutes* are expreſſed by acute accents, thus, '; the ſeconds by two, ''; the thirds by three, '''.

MINUTE, in *Computation of Time*, is uſed for the ſixtieth part of an hour.

MINUTE, in *Architecture*, uſually denotes the ſixtieth, ſometimes only the thirtieth part, or diviſion, of a MODULE.

MINUTE

MINUTE is alſo uſed to ſignify a ſhort memoir, or ſketch of any thing haſtily taken in writing.

In this ſenſe we ſay the *minutes* of the proceedings of the houſe of lords, &c.

MINUTES *of emerſion*. See EMERSION.

MINUTES, *meridional*. See MERIDIONAL.

MINUTE *tithes*, *minores decimæ*, ſmall tithes of wool, lambs, pigs, butter, cheeſe, &c. See TITHE.

MINX, in *Zoology*, is the name of an animal in North America, very much reſembling the OTTER.

MIPARTY, *chamber of*. See CHAMBER.

MIQUELETS, a kind of foot-ſoldiers, inhabiting the Pyrenean mountains; armed with piſtols under their belts, a carbine, and a dagger. The *miquelets* are dangerous people for travellers to meet.

MIRABILE, *rete*. See RETE.

MIRABILIS, in *Botany*. See MARVEL *of Peru*.

MIRABILIS *aqua*. See WATER.

MIRABOLANS, or MYROBALANS, in *Pharmacy*. See MYROBALANS.

MIRACLE, in a popular ſenſe, is a *prodigy*, or an extraordinary event, that ſurpriſes us by its novelty.

MIRACLE, in a more accurate and philoſophical ſenſe, is an effect that does not follow from any of the regular laws of nature; or which is inconſiſtent with ſome known law thereof; or contrary to the ſettled conſtitution and courſe of things: accordingly all *miracles* preſuppoſe an eſtabliſhed ſyſtem of nature, within the limits of which they operate, and with the order of which they diſagree.

Spinoza denies, that any power can ſuperſede that of nature; or that any thing can diſturb, or interrupt, the order of things: and accordingly defines a *miracle* to be a rare event, happening in conſequence of ſome laws that are unknown to us.

Divines define a *miracle*, an extraordinary and wonderful effect, above the power of nature, wrought by God, to manifeſt his power or providence; or to give credit to ſome meſſenger ſent from himſelf. Thus Jeſus Chriſt evinced the truth of his miſſion, and his doctrine, by *miracles*; and thus alſo did Moſes. But there are ſcarce any theological writers, that preciſely agree in their definition of a *miracle*. Mr. Locke defines it to be a ſenſible operation, which, being above the comprehenſion of the ſpectator, is, in his opinion, contrary to the courſe of nature, and taken by him to be divine. Dr. Clarke's definition of a *miracle*, in the theological ſenſe of the word, is this: that it is a work effected in a manner unuſual, or different from the common and regular method of Providence, by the interpoſition either of God himſelf or of ſome intelligent agent ſuperior to man, for the proof or evidence of ſome particular doctrine, or in atteſtation to the authority of ſome particular perſon. According to Dr. Sykes, a *miracle* is a deſigned effect, ſenſible, unuſual in itſelf, beyond the art and power of man to do. Dr. Chandler ſays, that a *miracle* is an action done, or an operation viſibly performed by any being, which is really and truly above the reach, natural power, and capacity of that being who does it, of himſelf, and without the aſſiſtance of ſome ſuperior agent to perform. With this Dr. Hutcheſon's definition nearly coincides, viz. that it is a work far exceeding human power, yet performed by the command, or upon the volition of a man. And the ſame writer farther obſerves, that, though *miracles* may prove the ſuperintendency of a voluntary agent, and that the univerſe is not guided by neceſſity or fate; yet that mind muſt be weak and inadvertent, who needs them to confirm the belief of a wiſe and good Deity; ſince the deviation from general laws, unleſs upon very extraordinary occaſions, muſt be a preſumption of inconſtancy and weakneſs rather than of a ſteady wiſdom and power; and muſt weaken the beſt arguments we have for the ſagacity and power of the univerſal mind. Inquiry into the original of the ideas of beauty, &c.

A late ingenious and learned writer objects to all thoſe definitions of *miracles*, which repreſent them as effects unuſual, above human power, and manifeſting the interpoſition of ſuperior power: becauſe, he ſays, the term unuſual does not diſtinguiſh real *miracles* from many things which are not miraculous ſuch as the rare and uncommon appearances of nature: nor does the calling a *miracle* and effect above human power diſtinguiſh it from all other effects equally above human power, produced by ſuperior beings, when acting within their uſual ſphere, which for that reaſon, cannot be miraculous. Beſides, as this definition comprehends many things, which are not miraculous, and to which no perſons apply the term; ſo it excludes many things which are allowed by all to be proper *miracles*. For there ſeems to be a difference between effects above human power, or which argue a higher degree of power; and effects which argue a power barely different from human, and in no manner ſuperior to it. According to this definition, beaſts and birds may work *miracles*; for they do many things that are above the power of man. Moreover, this definition, inſtead of deſcribing *miracles* by the nature of the works themſelves, deſcribes them by their author, and the degree of power neceſſary to their performance. To which it may be added, that works, which argue only a power more than human, can be no abſolute proofs of a divine interpoſition: and farther, the laſt part of the definition, manifeſting the interpoſition of ſuperior power, is ſuperfluous; becauſe it is only ſaying effects above human power muſt be produced by a power above it.

This writer conſiders the contrariety or conformity of the event itſelf to thoſe laws by which the world is governed in the courſe of God's general providence, as the only circumſtance which denominates and conſtitutes it a proper *miracle* or not: and, therefore, before we can pronounce with certainty any effect to be a true *miracle*, it is neceſſary, (and nothing more is neceſſary than) that the common courſe of nature be in ſome degree firſt underſtood. *Miracles*, in this view, are not impoſſible to the power of God, nor neceſſarily repugnant to our ideas of his wiſdom and immutability. Neither do they imply any inconſiſtency in the divine conduct, or a defect or diſturbance of the laws of nature: ſo that in the general idea of *miracles*, conſidered as variations from the common courſe of nature, there is nothing that can furniſh a certain univerſal proof againſt their exiſtence; and there is a power ſuperior to nature, which is ever able, and which in certain circumſtances may reaſonably over-rule what was at firſt eſtabliſhed. The writer, now cited, farther maintains, that *miracles* are neither the effects of natural cauſes, nor of ſuperior created intelligences, acting from themſelves alone; but that they are always to be aſcribed to a divine interpoſition; i.e. that they are never wrought, but either immediately by God himſelf, or by ſuch other beings as he commiſſions and empowers to perform them. In proof of this propoſition, he alledges, that the ſame arguments which prove the exiſtence of ſuperior created intelligences, do much more ſtrongly conclude againſt their acting out of their proper ſphere. Farther, the ſuppoſition of the power of any created agents to work *miracles* of themſelves, in this lower world, is contradicted by the obſervation and experience of all ages: there being, in *fact*, no proper evidence of the truth of any *miracles*, but ſuch as may be fitly aſcribed to the deity. Moreover, the laws of nature being ordained by God and eſſential to the order and happineſs of the world, it is impoſſible God ſhould delegate to any of his creatures a power of working *miracles*, by which thoſe divine eſtabliſhments may be ſuperſeded and controlled. Beſides, the aſcribing to any ſuperior beings, God excepted, and thoſe immediately commiſſioned by him, the power of working *miracles*, ſubverts the foundation of natural piety, and is a fruitful ſource of idolatry and ſuperſtition. It is farther urged, that if *miracles* were performed in favour of falſe doctrines, mankind would be expoſed to frequent and unavoidable deluſion: and, if they may be performed without a divine permiſſion, and in ſupport of falſhood, they cannot be credentials of a divine miſſion, and criterions of truth. So that, upon the whole, if ſuperior beings really poſſeſs the miraculous powers which ſome writers have aſcribed to them, the exerciſe of thoſe powers, by good and evil agents, would either expoſe mankind to neceſſary and invincible error, or entirely deſtroy the credit and uſe of *miracles*, under the idea of criterions of truth and authentic credentials of a divine miſſion. If we appeal to the evidence of revelation, on this ſubject, we ſhall find, that the view which the ſcripture gives us of good angels, of the devil and his angels, as alſo of the ſouls of departed men, is inconſiſtent with their liberty of working *miracles*: and the view which the ſacred writers give us of the gods of paganiſm is alſo abſolutely inconſiſtent with their poſſeſſing a power of working *miracles*. Nevertheleſs, it has been much diſputed, how far it may be in the power of the devil to work *miracles*? or wherein the ſpecific difference lies between the *miracles* of Moſes, and thoſe of Pharaoh's magicians? thoſe of Jeſus Chriſt and the apoſtles, and thoſe of Simon Magus and Apollonius Tyaneus? Whether the latter were any more than mere deluſions of the ſenſes; or whether any ſupernatural and diabolical power concurred with them? See MAGICIAN: under which article it is ſhewn, that the magicians, diviners, and ſorcerers of antiquity, who pretended, by the aſſiſtance of the heathen deities, &c. to foretel future events, or to work *miracles*, are branded in ſcripture as mere impoſtors, incapable of ſupporting their pretenſions by any works or predictions beyond human

human power or skill. The ſcripture likewiſe reproaches the pretences to inſpiration and *miracles*, made by falſe prophets, in ſupport of error and idolatry, as the foſe effects of human craft and impoſture. And, therefore, ſince angels, whether good or evil, the ſpirits of departed men, the heathen deities, magicians, and falſe prophets, are the only agents, who have ever been conceived as capable of working *miracles*, either in oppoſition to God, or without an immediate commiſſion from him; and the ſcripture denies to all theſe the power of performing any *miracles*, it does in effect deny, that any ſingle *miracle* has ever been performed without the immediate interpoſition of God. It is likewiſe alledged, that the ſcriptures repreſent the one true God, as the ſole creator and ſovereign of the world, which he governs by fixed and invariable laws; that to him they appropriate all *miracles*, and that they urge them as demonſtrations of his divinity and ſole dominion over nature, in oppoſition to the claims of all other ſuperior beings. The ſcriptures alſo uniformly repreſent all *miracles*, as being, in themſelves, an abſolute demonſtration of the miſſion and doctrine of the prophets, at whoſe inſtance they are performed; and never directs us to regard their doctrines as a teſt of the *miracles* being the effect of a divine interpoſition. Accordingly, the *miracles* of Chriſt, in particular, were a demonſtration (not a partial and conditional, but a complete and abſolute demonſtration) of his miſſion from God: and they were farther deſigned to evince his peculiar character as the Meſſiah or anointed; i. e. his regal commiſſion and power, or his right by divine deſignation to dominion and judicature over mankind. And it may be obſerved, with reſpect to all the *miracles* of the New Teſtament, that their divinity, conſidered in themſelves, is always either expreſſly aſſerted, or manifeſtly implied; and they are accordingly urged as a deciſive and abſolute proof of the divinity of the doctrine and teſtimony of their performers, without ever taking into conſideration the nature of the doctrine, or of the teſtimony to be confirmed. It is alſo ſhewn, that the ſcriptures have not recorded any influences of real *miracles* performed by the devil; in anſwer to the objections drawn from the caſe of the magicians in Egypt, from the appearance of Samuel, after his decaſe, to Saul, which was either the work of human impoſture or a divine *miracle*, and from our Saviour's temptation in the wilderneſs, which the writer, to whom we now refer, conſiders as a divine viſion. *Miracles* conſidered as the peculiar works of God, afford a divine teſtimony to the perſon on whoſe account they are wrought, and to that doctrine or meſſage, which he delivers in the name of God. And this proof from *miracles* of the divine commiſſion, and doctrine of a prophet, is in itſelf deciſive and abſolute. It is alſo the moſt natural and agreeable to the common ſenſe of mankind in all ages. It is the moſt eaſy and compendious proof of a new revelation. *Miracles* are farther a very powerful method of conviction, making a ſtrong impreſſion upon the heart, at the ſame time that they carry light to the underſtanding. Nor is the neceſſity of *miracles* leſs evident than their propriety and advantage, in atteſting a divine commiſſion and propagating a new revelation. They alſo ſerve to revive and confirm the principles of natural religion, and to recover men from thoſe two oppoite extremes of atheiſm and idolatry. Finally, the evidence of *miracles*, whether of power or knowledge, is the fitteſt to accompany a ſtanding revelation; becauſe it is not confined to one age or nation, but may be extended over the whole globe, and conveyed to the moſt diſtant generations. On the nature and deſign of *miracles*, already illuſtrated in this article, ſee Farmer's Diſſertation on *Miracles*, &c. 8vo. 1771. paſſim.

On the other hand, Dr. Clarke, who allows that *miracles* may be wrought by other agents beſides the Deity, obſerves, that it cannot certainly be diſtinguiſhed, by the *miracle* itſelf, whether any extraordinary interpoſition of ſome power ſuperior to men be the immediate interpoſition of God himſelf, or of ſome good angel, or of ſome evil angel. The only poſſible ways, ſays this learned writer, by which a ſpectator may certainly and infallibly diſtinguiſh whether *miracles* be indeed the works either immediately of God himſelf, or of ſome good angel employed by him; and conſequently the doctrine witneſſed by the *miracles* be infallibly true and divinely atteſted: or whether, on the contrary, the *miracles* be the works of evil ſpirits, and conſequently the doctrine a fraud and impoſition upon men, are theſe: if the doctrine atteſted by *miracles* be in itſelf impious, or manifeſtly tending to promote vice; then, without all queſtion, the *miracles*, how great ſoever they may appear to us, are neither wrought by God himſelf, nor by his commiſſion. If the doctrine, atteſted by *miracles*, be in itſelf indifferent, or ſuch as cannot, by the light of nature and right reaſon alone, be certainly known whether it be true or falſe; and, at the ſame time, in oppoſition to it, and in proof of the direct contrary doctrine, there be wrought other *miracles*, more and greater than the former, or at leaſt attended with ſuch circumſtances as evidently ſhew the power by which theſe latter are wrought to be ſuperior to the power that produced the former; then that doctrine, which is atteſted by the ſuperior power, muſt neceſſarily be believed to be divine. This, he apprehends, was the caſe of Moſes, and the Egyptian MAGICIANS. If, in the laſt place, the doctrine atteſted by *miracles* be ſuch as, in its own nature and conſequences, tends to promote the honour and glory of God, and the practice of univerſal righteouſneſs among men; and yet nevertheleſs be not in itſelf demonſtrable, nor could, without revelation, have been diſcovered to be actually true; and there is no pretence of more or greater *miracles*, on the oppoſite ſide to contradict it; which is the caſe of the doctrine and *miracles* of Chriſt; then the *miracles* are unqueſtionably divine, and the doctrine muſt, without all controverſy, be acknowledged as an immediate and infallible revelation from God. In order to elviate the objection, that we prove in a circle the doctrine by the *miracles*, and the *miracles* by the doctrine; he adds, that the *miracles*, in this way of reaſoning, are not at all proved by the doctrine; but only the poſſibility and the good tendency, or at leaſt the indifferency of the doctrine, are a neceſſary condition or circumſtance, without which the doctrine is not capable of being proved by any *miracles*. The doctrine muſt be in itſelf poſſible and capable of being proved, and then *miracles* will prove it to be actually true and certainly true. Boyle's Lecture, Sermons, &c. p. 226, &c.

The Romans attribute *miracles* to their emperors Adrian and Veſpaſian. The church of Rome abounds in *miracles*: if we believe their writers, ſome of their monks have wrought more *miracles* than all the apoſtles; and this without any viſible neceſſity for them.

As full as that church pretends to be of ſaints, it is a rule with them, that none are ever canonized till there be good proof of his having wrought *miracles*. So that were all thoſe allowed good *miracles*, and to have happened out of the common order of nature, they are ſo numerous, one would be tempted to think there was no order or law of nature at all.

Some proteſtant writers have maintained, that the power of working *miracles* was exerciſed in the Chriſtian church, during the three or four firſt centuries; in proof of which they alledge that of the THUNDERING *legion*, &c. But Dr. Middleton, in his Free Inquiry into the miraculous Powers, which are ſaid to have ſubſiſted in the Chriſtian Church, &c. has maintained a very different opinion. And it muſt be acknowledged, that the evidence of the facts is, to ſay the leaſt of it, very doubtful.

The many and ſtupendous *miracles*, which are ſaid to have been wrought by the Chriſtian miſſionaries, who were ſent to convert the barbarous nations, in the eighth century, have loſt, in our times, the credit they obtained in former ages.

St. Auguſtine is a ſtrong advocate for *miracles*. He mentions ſeveral, whereof he was an eye-witneſs; and others, whereof he was informed by thoſe that were. In the ſingle city of Hippo, he tells us there were ſeventy *miracles* wrought in the ſpace of two years, on the building a chapel in honour of St. Stephen. There are thoſe, however, who ſet aſide the authority of all *miracles*; thinking it unbecoming the wiſdom of God to eſtabliſh ſuch laws, as that he ſhould find it frequently neceſſary to ſuperſede. And as the former, from the avowed authority of ſome *miracles*, fetch an argument for the truth of all, pleading thoſe which are allowed as well as thoſe which are queſtioned; ſo theſe alledge the falſe ones, very unfairly, as concluſions againſt all.

MIRACLE, *chemical*. See MAGNESIA.

MIRALETUS, in *Ichthyology*, a name given by Bellonius, and ſome other writers, to the ſpecies of ray, commonly called by others *raja oculata*. This is accurately diſtinguiſhed, by Artedi, by the name of the ray with a ſmooth back and belly, and with a row of ſpines round the eyes, and three other rows of them on the tail.

MIRE *drum*, or MIRE *ſnipe*. See BITTERN, and HERON.

MIRROR, a *ſpeculum*, or body, which exhibits the images of objects preſented to it by reflection.

The uſe of *mirrors* is very ancient. Mention is made of brazen *mirrors*, or looking-glaſſes, in Exodus xxxviii. 8. where Moſes is ſaid to have made a *brazen laver*, or baſon, *of the looking-glaſſes of the women continually aſſembled at the door of the tabernacle*. It is true ſome modern

commentators will not allow the *mirrors* themſelves to have been braſs; but of glaſs, only ſet or framed in braſs. But the moſt learned among the rabbins do all allow, that in thoſe times the *mirrors* made uſe of by the Hebrew women in dreſſing their heads were of metal; and that the devout women, mentioned in this paſſage, made preſents to Moſes of all their *mirrors*, to make the brazen laver. See the Jeſuit Bonfrerius's comment on this text. See GLASS.

It might likewiſe be proved, that the ancient Greeks made uſe of brazen *mirrors*, from divers paſſages among the ancient poets.

MIRROR, in the more confined ſenſe of the word, is peculiarly uſed to ſignify a ſmooth ſurface of glaſs, tinned and quickſilvered on the back-ſide; which exhibits the images of objects oppoſed thereto. See LOOKING-GLASS.

MIRROR, in *Catoptics*, denotes any poliſhed body impervious to the rays of light, and which of conſequence reflects them equally.

Thus water in a deep well or river, and ſmooth poliſhed metals, are ranked among the number of *mirrors*.

In this ſenſe, the doctrine of *mirrors* makes the ſubject of CATOPTRICS.

The doctrine of MIRRORS *is founded on the following general principles.* 1. Light reflected from any *mirror*, or ſpeculum, makes the angle of incidence equal to that of reflection; which ſee demonſtrated under the word REFLECTION.

Hence, a ray of light, as H B, *(Tab.* II. *Optics, fig.* 26. N° 2.) falling perpendicularly on the ſurface of a ſpeculum D E, will be reflected back upon itſelf: as we find by experience it actually is.

From the ſame point of a *mirror*, therefore, B, there cannot be ſeveral rays reflected on the ſame point; ſince, in that caſe, all the angles of incidence muſt be equal to the ſame angle of reflection C B G, and therefore to each other; which is abſurd. Nor can the ray A B be reflected to two or more points; ſince, in that caſe, all the angles of reflection would be equal to the ſame angle of incidence A B F: which is likewiſe abſurd.

2. From every point of a *mirror*, are reflected rays thrown on it from every point of a radiant object. Since then rays coming from different parts of the ſame object, and ſtriking on the ſame point of the *mirror*, cannot be reflected back to the ſame point; the rays which flow from different points of the ſame radiating object are again ſeparated after reflection: ſo that each point ſhews whence it came.

Hence it is, that the rays reflected from *mirrors* exhibit the objects to view. Hence alſo, it appears, that rough uneven bodies muſt reflect the light in ſuch manner as that rays coming from different points will be blended or thrown confuſedly together.

Mirrors may be divided into *plane*, *concave*, *convex*, *cylindrical*, *conical*, *parabolical*, and *elliptical*.

MIRRORS, *plane*, are thoſe which have a plane or flat ſurface.

Theſe, by a popular name, we call *looking-gloſſes*.

For the manner of making plane *mirrors*, or ſpecula, ſee LOOKING-GLASS.

MIRRORS, *laws and phenomena of plane.* 1. In a plane *mirror*, every point of an object, as A, *(Tab* IV. *Optics, fig.* 65.) is ſeen in the interſection B, of the cathetus of incidence A B, with the reflected ray C B.

Let C D and F E be two reflected rays, correſponding to the incident rays A D, A E: then, ſince the vertical angle C D G = E D B; and the angle of reflection C D H = A D G the angle of incidence, A D H will be = C D G = E D B. And H E F = D E B, and H E F = A E G, therefore D E B = A E G. But A E G + A D E, as well as B E D + B D E, are leſs than two right angles; conſequently the reflected rays F E and C D meet in B, and in the equiangular triangles A D E and D E B, having D E common, D B = D A. Wherefore, ſince the angle B D G = C D H = A D G, the angles at G will be equal, and conſequently A B perpendicular to H G; i. e. A B is the cathetus of incidence: and, therefore, the reflected rays F E and C D meet with the cathetus of incidence A B in the ſame point B: and the radiant point A is ſeen in B.

Hence, 1. as all the reflected rays meet with the cathetus of incidence in B; by whatever reflected ray the radiant point A be ſeen, it will ſtill appear in the ſame place. Conſequently, any number of perſons, viewing the ſame object in the ſame *mirror*, will all ſee it in the ſame place behind the *mirror*. And hence it is, that the ſame object has only one image, and that we do not ſee it double with both eyes.

Hence, alſo, the diſtance of the image B, from the eye C, is compounded of the ray of incidence A D, and the reflected ray C D: and the object A radiates reflectedly in the ſame manner as it would do directly, were it removed into the place of the image.

2. The image of a radiant point, B, appears juſt ſo far behind a plane *mirror*, as the radiant point is before it: becauſe A G = B G.

Hence, if the *mirror* H G be placed horizontally, the point A will ſeem ſo much below the horizon, as it is really elevated above it: conſequently, erect objects will appear as if inverted; and therefore men ſtanding on their feet, as if on their heads. Or, if the *mirror* be faſtened to the ceiling of a room, parallel to the horizon, objects on the floor will appear above the ceiling as much as they really are below it, and inverted.

3. In a plane *mirror*, the images are perfectly ſimilar, and equal to the objects; for every point of the object is ſeen in the catheti of incidence, and the *mirror* biſects that part of it which is intercepted between the radiant point and its image. And hence the uſe of *mirrors* as looking-glaſſes.

4. In a plane *mirror*, things on the right hand appear as on the left; and *vice verſa*.

Hence, alſo, we have a method of meaſuring any inacceſſible altitude, by means of a plane *mirror*. Thus, the *mirror* being placed horizontally in C, *(fig.* 66.) retire from it till ſuch time as the top of the tree be ſeen therein. Meaſure the height of the eye D E, the diſtance of the ſtation from the point of reflection E C, and the diſtance of the foot of the tree from the ſame: then to E C, C B, and E D, find a fourth proportional A B. This is the altitude ſought.

5. If a plane *mirror* A E *(fig.* 67.) be inclined to the horizon E H, in an angle of 45 degrees, an object C B perpendicular to it will appear parallel I K, and the horizontal object I B perpendicular in M K.

For produce B C till it meets the *mirror* in A: then as H is a right angle, and E = 45°, A will be = 45°: therefore, if from B be drawn B G perpendicular to the *mirror* A E, A B G will be = 45°; and A G = G B. Let G K be = G B, and the image of B will be in K: draw K A, and becauſe K G = G A and G a right angle, K will be = 45°, and therefore K A parallel to E H. In the ſame manner it may be ſhewn, that the point C would appear in I, and conſequently the image I K will be parallel to the horizon E H; and *vice verſa*. Hence, the eye being placed beneath the *mirror*, the earth will appear perpendicularly over it; or if placed over it, the earth will appear perpendicularly under it. Hence, alſo, a globe, deſcending down a plane a little inclined, may, by means of a *mirror*, be exhibited as mounting up a vertical plane, to the great ſurprize of ſuch as are unacquainted with catoptrics. And hence we have a method of repreſenting ourſelves as if flying: for a *mirror* inclined to the horizon under an angle of 45°, we have obſerved, will repreſent vertical objects as if horizontal; conſequently, a large *mirror* being ſo diſpoſed, as you advance towards it, you will ſeem to move horizontally; and nothing will be wanting to the appearance of flying, but to ſtrike out the arms and legs. It muſt be added, however, that as the floor is elevated along with you, your feet will ſtill be ſeen to walk as along a vertical plane. To deceive the eye entirely, therefore, it muſt be kept from the feet.

6. If the object A B *(fig.* 68.) be parallel to the ſpeculum C D, and equally diſtant from it, with the eye; the reflecting line C D will be half the length of the object A B.

Let the eye O be in the object A B, or let the ſpectator view himſelf in a glaſs. Since A B is parallel to C D, the image G H will be parallel to it likewiſe.—From O let fall O L perpendicular to C D, which, continued to I, will be alſo perpendicular to G H; therefore, O L and O I will be the reſpective altitudes of the triangles O C D and O G H, which triangles, having the angles $n = o$ and $u = y$ are ſimilar: conſequently, C D : G H :: O L : O I: and as O L = ½ O I by art. 2 above, C D will be = ½ G H = ½ A B.

And hence, to be able to ſee the whole body in a plane *mirror*, its height and breadth muſt be half your height and breadth. Conſequently, the height and breadth of any object to be ſeen in a *mirror* being given, we have alſo the height and breadth of the *mirror* wherein the whole object will appear, at the ſame diſtance with the eye.

Hence alſo, as the length and breadth of the reflecting part of the ſpeculum are ſubduple of thoſe of the object to be reflected; the reflecting part of the *mirror* is to the ſurface reflected in a ſubquadruple ratio. Conſequently, the reflecting portion being a conſtant quantity, if in any place you ſee the whole body in a *mirror*, you will ſee it in every other place, whether you approach nearer or recede farther from it.

7. If an object A B *(fig.* 69. N° 2.) be parallel to the *mirror*

EF; the length of the reflected line AB is to the reflecting part of the ſpeculum CD as the ſum of the incident and reflected rays BD + DO to the reflected ray OD; or, as the ſum of the diſtances of the eye and of the object from the ſpeculum, viz. OI + BF to the diſtance of the eye OI. For GE : CD :: OE : OD; i. e. becauſe GE = AB, and DE = DB, AB : CD :: OD + DB : OD. Moreover, OE : OD :: OK : OI, therefore GE : CD :: OK : OI; conſequently, ſince IK = FE = BF, and GE = AB, we ſhall have AB : CD :: OI + BF : OI.

8. A ſpectator will ſee his own image as far beyond the ſpeculum as he is before it; and as he moves to or from the ſpeculum, his image will, at the ſame time, move towards or from him on the other ſide, but apparently with a double velocity, becauſe the two motions are equal and contrary. In like manner, if while the ſpectator is at reſt, an object be in motion, its image behind the ſpeculum will be ſeen to move at the ſame rate. And if the ſpectator moves, the images of objects that are at reſt will appear to approach or recede from him, after the ſame manner as when he moves towards real objects.

9. If ſeveral *mirrors*, or ſeveral fragments or pieces of a *mirror*, be all diſpoſed in the ſame place, they will only exhibit an object once.

10. If two plane *mirrors*, or ſpecula, meet in any angle, the eye, placed within that angle, will ſee the image of an object placed within the ſame, as often repeated as there may be catheti drawn determining the places of the images, and terminated without the angle.

Hence, as the more catheti, terminated without the angle, may be drawn as the angle is more acute; the acuter the angle, the more numerous the images. Thus Z. Traber found, at an angle of one third of a circle, the image was repreſented twice, at ½ thrice, at ⅓ five times, and at ⅙ eleven times.

Farther, if the *mirrors* be placed upright, and ſo contracted; or if you retire from them, or approach to them, till the images reflected by them coaleſce, or run into one, they will appear monſtrouſly diſtorted: thus, if they be at an angle ſomewhat greater than a right one, the image of your face will appear with only one eye; if the angle be leſs than a right one, you will ſee three eyes, two noſes, two mouths, &c. At an angle ſtill leſs, the body will have two heads. At an angle ſomewhat greater than a right one, at the diſtance of four feet, the body will be headleſs, &c. Again, if the *mirrors* be placed, the one parallel to the horizon, the other inclined to it, or declined from it, it is eaſy to perceive, that the images will be ſtill more romantic. Thus, one being declined from the horizon to an angle of 144 degrees, and the other inclined to it, a man ſees himſelf ſtanding with his head to another's feet.

Hence it appears, how *mirrors* may be managed in gardens, &c. ſo as to convert the images of thoſe near them into monſters of various kinds; and ſince glaſs *mirrors* will reflect the image of a lucid object twice or thrice, if a candle, &c. be placed in the angle between two *mirrors*, it will be multiplied an infinite number of times.

On theſe principles are founded various catoptric machines, ſome of which repreſent objects infinitely multiplied and diſtorted; others infinitely magnified, and ſet at vaſt diſtances.

MIRRORS, *burning*. See BURNING-*glaſs*.

MIRRORS, *convex*, are thoſe whoſe ſurface is convex.

Note, by *convex* ſurfaces, authors generally mean ſuch as are ſpherically convex.

Manner of preparing or making convex ſpecula, or MIRRORS. There are various methods uſed by divers artiſts; particularly as to the matter or compoſition for the ſilvering. One of the beſt that is known, is given us by Wolfius thus:

Melt one part of tin, another of biſmuth, together; and to the melted maſs add two parts of mercury: as ſoon as the mercury begins to evaporate into ſmoke (which it preſently does), the whole compoſt is to be thrown into cold water, and when well cooled, the water decanted off. The mixture is then to be ſtrained through a linen cloth two or three-fold; and what is thus ſeparated, poured into the cavity of a glaſs ſphere: this ſphere is to be turned gently round its axis till the whole ſurface is covered, the reſt being reſerved for future uſe.

If the ſpheres were of coloured glaſs, the *mirror* will be ſo too. And in the ſame manner may conic, elliptic, cylindric, and other *mirrors*, be made.

How they may be made of metal, ſee under *concave* MIRROR. See alſo SPECULUM.

MIRRORS, *laws or phænomena of convex*. 1. In a ſpherical convex *mirror*, HCI (*fig.* 70.) the reflected ray EM concurs with the cathetus of incidence DL, and the incident ray DN with the cathetus of reflection EL, between the tangent AB, and the center L. For the perpendiculars, or catheti of incidence, obliquation, and reflection, are in the plane of reflection, and, therefore, in the plane which touches the ſpeculum in the point of incidence C; the tangent AC makes a right angle with the cathetus of obliquation FC; but the reflected ray EC or CM, makes with it an acute angle *x*, and, therefore, falls between the tangent AC, and the cathetus of obliquation CL. Wherefore, ſince CL and DL meet in the center L, the reflected ray EM ought to interſect the cathetus of incidence DL between the tangent and the center. In the ſame manner it is ſhewn, that the incident ray DN ought to meet with the cathetus of reflection between the tangent and the center. Hence, the image of a radiant point appears between the center and the tangent, becauſe it appears in the concourſe of the reflected ray and catheti of incidence.

2. In a ſpherical convex *mirror*, the cathetus of incidence DL (*fig.* 70.) is to DP, the diſtance of the object from the tangent at the point of reflection C, as LM, the diſtance of the image from the center, is to MP, the diſtance of the image from the tangent. Since $a = x$, and $x = m$, q will be equal to m, and, therefore, the right line CP biſecting the angle DCM, cuts the baſe DM into two parts, which are in the ſame proportion with the ſides; conſequently, DP : PM :: DC : CM; and if DF be drawn parallel to CM, a will be $= p$, and, as $a = q$, $p = q$, and DF = DC. Therefore, ſince DF (DC) : MC :: DL : ML, DL will be to ML :: DP : PM; and, therefore, DL : DP :: ML : PM. Hence, becauſe DL > DP, and ML > PM; and, therefore, ML much greater than RM, the diſtance of the image from the center is greater, but from the tangent leſs than half the ſemidiameter; and the image is nearer to the tangent than the center.

Hence, alſo, the diſtance of the object from the tangent is greater than that of the image; and, conſequently, the object is farther diſtant from the ſpeculum than the image.

3. If the arch BD (*fig.* 71.) intercepted between the point of incidence D, and the cathetus AB; or the angle C, formed in the center of the *mirror* by the cathetus of incidence AC, and that of obliquation FC, be double the angle of incidence, the image E will appear on the ſurface of the ſpeculum.

4. If the arch intercepted between the point of incidence, and the cathetus; or the angle C, formed in the center of the *mirror* by the catheti of incidence, and the cathetus of obliquation be more than double the angle of incidence, the image will be without the *mirror*.

5. If the arch intercepted between the point of incidence, and the cathetus; or the angle, formed in the center of the *mirror* by the catheti of incidence, and that of obliquation, be leſs than double the angle of incidence, the image will appear within the ſpeculum.

6. In a convex *mirror*, a remoter point A (*fig.* 72.) is reflected from a point F, nearer the eye O, than any nearer point B in the ſame cathetus of incidence.

Hence, if the point of the object A be reflected from the point of the *mirror* F, and the point of the object B, from the point of the *mirror* E; all the intermediate points between A and B will be reflected from the intermediate points of the ſpeculum between F and E; and, conſequently, FE will be the line that reflects AB.

Hence, alſo, a point of the cathetus B ſeems at a greater diſtance CB from the center C, than a more remote one, A.

7. A nearer point B (*fig.* 73.) not in the ſame cathetus with a remoter H, is reflected to the eye O, from a nearer point of the ſpeculum, than the remoter H.

Hence, if the point of an object A be reflected from the point of a *mirror* C, and the point of the object B, from the point of the ſpeculum D, all upon the ſame point O; all the intermediate points between A and B will be reflected from all the intermediate points between C and D. Conſequently, the image FG of the object BA is contained between the cathetus BE and AE.

8. In a ſpherical convex *mirror*, the image is leſs than the object.

And hence the uſe of ſuch *mirrors*, in the art of painting, where objects are to be repreſented leſs than the life.

9. In a convex *mirror*, the more remote the object, the leſs its image; and, again, the ſmaller the *mirror*, the leſs the image.

10. In a convex *mirror*, the right hand is turned to the left, and the left to the right; and magnitudes perpendicular to the *mirror* appear inverted.

11. The image of a right line, perpendicular to the *mirror*, is a right line; but that of a right line either oblique to the *mirror*, or parallel thereto, is convex.

12. Rays reflected from a convex *mirror* diverge more than if reflected from a plane *mirror*.

Hence light, by being reflected from a ſpherical *mirror*,

is weakened; and, consequently, the effects of reflected light are weaker than those of direct. Hence also, myopes see remote objects more distinctly in a convex *mirror*, than they do directly.

Rays reflected from a convex *mirror* of a smaller sphere diverge more than those reflected from a larger. Consequently, the light is more weakened, and its effects are less considerable in the former case than the latter.

MIRRORS, *concave*, are those whose surface is concave. These are generally made of a mixed metal.

Note, by *concave*, authors commonly mean *spherically concave*.

MIRRORS, *manner of preparing or making concave*. First, a mould is to be provided for casting them. In order to this, take clay well dried, pulverize and sift it, mix it up with water, and then strain or filtre it; with this, work up horse-dung, and hair shred small, till the mass be sufficiently tough; to which, on occasion, may be added charcoal-dust, or brick-dust, well sifted.

Two coarse moulds are then prepared of a gritty stone, the one concave, the other convex; which are to be ground by one another with wet sand between, till such times as the one perfectly fits the other. By this means a perfect spherical figure is acquired.

The mass, prepared before, is now to be extended on a table, by means of a wooden roller, till it be of a thickness proper for the *mirror*; and then being strewed with brick-dust to prevent its sticking, it is laid over the convex mould, and so gets the figure of the *mirror*. When this is dry, it is covered with another lay of the same mass; which once dried, both the covers, or segments of the clay, are taken off. The innermost of the two being laid aside, the stone mould is anointed with a pigment prepared of chalk and milk, and the outer cover again put over it.

Lastly, the joining being covered over with the same clay wherein the cover is formed, the whole mould is bound together with iron wire, and two holes are cut through the cover, the one for the melted matter of the *mirror* to be poured through, the other for the air to escape at, to prevent the *mirror's* being spoiled with bubbles.

The mould being thus prepared, eight parts of copper, one of English tin, and five of bismuth, are melted together; a little of the mixture is taken out with a ladle, and, if it be too red, when cold, more tin is put in; if too white, more copper: the mass in then poured into the mould before prepared, and so assumes the figure of a *mirror*.

Some with ten parts of copper mix four of English tin, and a little antimony and sal ammoniac, stirring the mass about as long as any fumes arise in it: others have other compositions, many of which are described by Schottus and Zahnius.

The *mirror*, being thus cast, is cemented to a wooden frame, and thus worked to and fro over the convex stone mould, first with water and sand, and, lastly, without sand, till it be fit for polishing; the stone mould is then covered with paper, and that is smeared over with tripoli dust, and cake of tin, over which the *mirror* is worked to and fro till it has got a perfect polish. And in the same manner are glass *mirrors* polished, excepting that the convex surface is there worked in the concave mould.

When the *mirrors* are very large, they are fixed on a table, and first ground with a gritty stone, then with pumice, then with fine sand, by means of a glass cemented to a wooden frame; and, lastly, they are rubbed with cake of tin, and tripoli dust, on a wet leather.

For concave *mirrors* of glass, the mould is usually made of alabaster; the rest is as in metal *mirrors*. See SPECULUM, GRINDING, and POLISHING.

MIRRORS, *laws and phenomena of concave*. 1. If a ray, as KI (*fig.* 74.) fall on a concave *mirror* EI, under an inclination of 60 degrees, and parallel to the axis AB, the reflected ray IB will concur with the axis AB in the pole of the glass B. Since $m=60°$, n also will be $=60°$, and because KI is parallel to the axis AB, $i=60°$, and $s=60°$; therefore CB=CI, the radius. Consequently the point B, in which the reflected ray IB concurs with the axis, is in the surface of the speculum. If the inclination of the incident ray be less than 60 degrees, as that of EI, the reflected ray EF will concur with the axis at the distance BF, which is less than a fourth part of the diameter. Since $i=s$, and, on account of the parallels HE and AB, $s=y$, we shall have $x=y$, and, therefore, FE=FC; but CF+EF>EC, and CE=CB; therefore CF+EF>CB; consequently CF>FB; i. e. FB is less than half the radius CB, or a fourth part of the diameter. And, universally, the distance of the point F, wherein the ray HE concurs with the axis, from the center C, is to half the radius CD in the ratio of the whole sine, to the cosine of inclination. For by the last demonstration it appears, that FE is $=$ FC; therefore if from F a perpendicular FD be let fall on EC, DC will be $=\frac{1}{2}$CE; but if CF be taken for the whole sine, CD will be the sine of the angle DFC, or the cosine of the angle DCF, i. e. of the inclination DEH; and, therefore, CF is to CD as the whole sine is to the cosine of the inclination.

Hence it is inferred, by calculation, that in a concave spherical *mirror*, whose breadth subtends an angle of six degrees, parallel rays meet, after reflection, in a part of the axis less than the one thousand four hundred fifty-seventh part of the radius: if the breadth of the concave *mirror* be 12, 18, 24, 30, 36 degrees; the part of the axis wherein the parallel rays meet, after reflection, is less than $\frac{1}{232}$, $\frac{1}{104}$, $\frac{1}{57}$, $\frac{1}{36}$, the radius.

And on this principle it is, that BURNING-*glasses* are formed.

For since the rays diffused through the whole surface of the concave *mirror*, after reflection, are contracted into a very small compass, the light and heat of the parallel rays must be prodigiously increased thereby; viz. in a duplicate ratio of the breadth of the *mirror*, and the diameter of the circle wherein all the rays are collected; and since the sun's rays are, as to any purposes on earth, parallel, it is no wonder that concave *mirrors* should burn with so much violence.

From this same principle is likewise deduced a method of representing the images of objects in a dark room; which see under CAMERA *obscura*.

2. A lucid body being placed in the focus F, of a concave *mirror* EI (*fig.* 74.) the rays, after reflection, become parallel. For parallel rays are by reflection united in a focus; but if the luminous body be in the focus F, that which was before the reflected ray EF will be now the incident ray, and *vice versâ*, therefore the reflected ray EH will now become parallel to the axis AB, and all the reflected rays parallel to one another.

Hence an intense light may be projected to a vast distance, by a lighted candle, &c. placed in the focus of a concave *mirror*.

Hence, also, if the parallel rays be received by another concave *mirror*, they will again concur in its focus, and burn.

Zahnius mentions an experiment of this kind made at Vienna, where two concave *mirrors*, the one six, the other three feet diameter, being placed about twenty-four feet apart, with a live coal in the focus of the one, and a match and tinder in the other, the rays of the coal lighted the tinder.

3. If a lucid body be placed between the focus F (*fig.* 75.) and the *mirror* HBC, the rays, after reflection, will diverge from the axis BA. If the lucid body were in F, the reflected ray CE would be parallel to the axis AB, and therefore it would constantly preserve the same distance from the axis. But since DCG>FCG, KCG will be > ECG; and, therefore, CK will fall beyond CE, and cannot be parallel to the axis, but must continually diverge from the axis, the distance from it increasing: whence it follows, that light is weakened by reflection.

4. If a lucid body be placed between the focus F, and the center G, as in I, the rays, after reflection, will meet in the axis beyond the center. In this case IHG < FHG, and, therefore, GHA < GHI; consequently, the reflected ray HA recedes from the parallel towards the axis, and its distance from the axis will be continually diminished, till at length it concurs with the axis. But if the lucid body be placed in A, that which was before the reflected ray AH will now become the incident ray, and *vice versâ*. If, therefore, the lucid body be placed beyond the center G, the rays after reflection will concur with the axis between the focus F and center G.

Hence, if a candle be placed in I, the image will appear in A; if it be placed in A, its image will be in I; in the intermediate points between I and A, the section of light will be a circle; and that so much the greater, as it is nearer the point of concourse.

5. If a luminous body be placed in the center of the *mirror*, all the rays will be reflected back upon themselves; for as they fall perpendicularly on the speculum, they will be reflected into themselves.

Hence, if the eye be placed in the center of a concave *mirror*, it will see nothing but itself, and that confusedly through the whole *mirror*.

6. If a ray falling from the point of the cathetus *h* (*fig.* 76.) on the convex *mirror* EF, be, together with its reflex IF, continued within the concavity of the *mirror*, FH will be the incident ray from the point of the cathetus H, and FO its reflex. For $\angle$FE=IFM; but $\angle$E=MFO, and IFM=EFH; therefore MFO=EFH; and, consequently, if HF be taken for the incident ray from the point H, FO will be the reflected rays.

Hence, since the point of the cathetus H is the image of

the point *b* in the convex *mirror*, but the point *b* the image of H in the concave; if the image of an object, reflected by a convex ſpeculum, be ſeen by a reflection made in its concavity, it will appear like the object itſelf.

And ſince the image of an infinite cathetus is leſs in a convex glaſs than one fourth of its diameter, a portion of the cathetus, leſs than a fourth part of the diameter, may appear of any magnitude required in a concave one. A point, therefore, diſtant from a concave ſpeculum leſs than one fourth of the diameter, muſt appear behind the *mirror* at any diſtance, how great ſoever.

Since then the image of any object, how broad ſoever, is contained in a convex ſpeculum, between the two lines of incidence of its extreme points; if an object be placed between the two lines, at a diſtance leſs than one fourth of its diameter, the breadth of the image, how great ſoever, may all appear.

Since then the image of an object included between two lines, at a diſtance leſs than one fourth of the diameter, may exceed the juſt height and breadth of the object; any, may be made of any magnitude, how big ſoever: objects placed between the focus and *mirror* muſt appear of enormous magnitudes in concave *mirrors*; the image being ſo much the greater in the concave *mirror*, as it is leſs in the convex.

In a convex *mirror*, the image of a remote object appears nearer the center than that of a nearer object: therefore, in a concave *mirror*, the image of an object remote from the *mirror* appears at a greater diſtance than that of a nearer object, provided the diſtance of the object from the center be leſs than a fourth part of the diameter.

In a convex ſpeculum, the image of a remote object is leſs than that of a near one: therefore, in a concave one, the image of an object placed between the focus and the *mirror*, is nearer the focus than the ſpeculum.

The image, therefore, of an object receding continually from a concave ſpeculum, becomes continually greater, provided it do not recede beyond the focus, where it becomes confuſed; and as it approaches, it grows continually leſs.

In a convex ſpeculum, if the ſphere, whereof it is a ſegment, be ſmaller, the image is ſmaller than in another of a larger ſphere: therefore in a concave, if the ſphere, whereof it is a ſegment, be ſmaller, the image will be larger than in another whoſe ſphere is larger: whence concave *mirrors*, if they be ſegments of very ſmall ſpheres, will do the office of microſcopes.

7. If an object AB (*fig.* 77.) be placed between a concave *mirror* and its focus, its image will appear behind the *mirror*, in an inverted ſituation. Let AB be the length of the object: ſince the point A is ſeen in the cathetus C*a*, and the point B in the cathetus C*b*, the higher point is ſeen in the higher place *a*, and the lower in the lower *b*; or the object appears behind the *mirror* in an erect ſituation. But if AB repreſent the breadth of the object, it appears in the ſame manner that the part to the right correſponds with the right and the left to the left, both of the object and image. However, in direct viſion the right hand part of an object correſponds to the left of the ſpectator, and the left to the right; and, therefore, in a concave ſpeculum, the parts to the left hand of an object between the focus and ſpeculum appear to the right, and the right to the left.

8. If an object AB (*fig.* 78.) be placed between the focus and the center, its image EF will appear inverted, and in the open air, beyond the center, the eye being placed beyond the center. For the rays, by which the point A is reflected, concur in the cathetus GF, beyond the center C in F, and thoſe by which the point B is reflected, concur in the cathetus DE, beyond the center C in E: therefore the point B radiates on the eye placed beyond EF as from E, and the point A as from F; conſequently B is ſeen in E, and A in F, and the image of the object is ſeen beyond the center in an inverted poſition.

9. If an object EF be placed beyond the center C, and the eye likewiſe beyond the center, the image will appear inverted in the open air, between the center and the focus.

Hence, the inverted images of objects placed beyond the center, are reflected by a concave *mirror*, erect; and may be received on a paper applied between the center and the focus, eſpecially if the room be dark: if the object EF be farther diſtant from the center than the focus, the image will be leſs than the object; becauſe AC is leſs than EC, and, therefore, AB ∠ EF.

On this principle, concave *mirrors*, eſpecially thoſe which are ſegments of large ſpheres, and are capable of reflecting entire objects, exhibit many pleaſing phænomena. Thus, if a man flouriſh his ſword againſt the *mirror*, neither comes out thereof, and meets him with the ſame motions; and the image of his head coming out of the *mirror*, if he ſtrike it with his real ſword, the imaginary ſword will ſtrike his real head. If he ſtretch out his hand, another hand will be ſtretched out of the *mirror*, and meet it at a great diſtance in the open air, &c. And on the ſame principle are conſtructed catoptric ciſtulæ, which, when looked into, exhibit images much bigger than the cheſt. See CATOPTRIC *ciſtula*.

10. The image of a right line, perpendicular to a concave *mirror*, is a right line; but all oblique or parallel lines are concave. For ſince every point of a line perpendicular to the ſpeculum is in the cathetus of incidence, its image will of courſe be a right line. But if AB (*fig.* 77.) be parallel, or oblique to the ſpeculum, and CF be drawn from the center C perpendicular to AB, CA will be greater than CD; and, therefore, as CF = CE. FD ∠ AE; conſequently the point D will appear farther behind the ſpeculum than A. Therefore ſince *c* is farther diſtant from D, than *a* from A, and *b* from B, the image *a c b* will appear concave.

MIRRORS, *cylindrical*, *conical*, *parabolical*, and *elliptical*, or ſpecula, are thoſe terminated by a ſurface reſpectively cylindrical, conical, parabolical, and ſpheroidical.

To prepare, or make, cylindrical, *conical*, *parabolical*, *elliptical*, and *hyperbolical* MIRRORS. For the *cylindrical* and *conical* ſort, if they are to be of glaſs, the method of preparing them is the ſame as that already laid down for convex *mirrors*.

If of metal, they are to be made after the manner of concave *mirrors*, only that the clay moulds there deſcribed, require other wooden ones of the figure of the *mirror*.

For *elliptical*, *parabolical*, and *hyperbolical mirrors*, the mould is to be thus prepared. On a wooden or brazen plane or table, deſcribe the figure of an elliplis, AB (*fig.* 79.) a parabola, or an hyperbola, CD (*fig.* 80.) after the manner taught under thoſe heads; which done, cut out the figure from the plane with all the accuracy imaginable.

To the elliptic figure fit an axis, as EF, with two fulcra to ſuſtain it, &c. and a handle to move it; lay a quantity of the clay, above deſcribed, under it; and turn about the axis by the handle, till the plane AB hath turned, or impreſſed the elliptical figure exactly upon it.

The axis of the parabolical or hyperbolical figure CD, is to be fixed at the vertex E in ſuch a manner as that it may always remain erect; this is to be turned about as above, till it hath given its own figure to the clay applied about it.

The part of the mould, thus formed, is to be dried, and either ſmeared over with fat, or ſprinkled with brick-duſt; then a convex mould is to be made, by putting a quantity of the ſame clay into the cavity thus formed. This latter is called the *male*, as the former the *female* mould.

The male mould, being well dried, is to be applied within the female, in ſuch manner, as only to leave the intended thickneſs of the *mirror* between them. The reſt as for concave *mirrors*.

Theſe *mirrors* are not made without the utmoſt difficulty; becauſe, if the moulds be ever ſo juſt, the figure of the *mirror* is apt to be damaged in the GRINDING. See SPECULUM.

MIRRORS, *phænomena, or properties of cylindrical*. 1. The dimenſions of objects correſponding lengthwiſe to the *mirror* are not much changed; but thoſe correſponding breadthwiſe have their figures altered, and their dimenſions leſſened ſo much the more, as they are farther from the *mirror*; whence ariſes a very great diſtortion.

2. If the plane of reflection cut the cylindric *mirror* through the axis, the reflection is performed in the ſame manner as in a plane *mirror*; if it cut it parallel to the baſe, the reflection happens in the ſame manner as in a ſpherical *mirror*; if, laſtly, it cut it obliquely, or be oblique to its baſe, the reflection is the ſame as in an elliptical *mirror*.

Hence, as the plane of reflection never paſſes through the axis of the *mirror*, except when the eye and objective line are in the ſame plane; nor parallel to the baſe, except when the radiant point and the eye are at the ſame height, the reflection, in a cylindrical *mirror*, is uſually the ſame as in an elliptical one.

3. If a hollow cylindrical *mirror* be oppoſed directly to the ſun, inſtead of a focus of a point, the rays will be reflected into a lucid line, parallel to its axis, at a diſtance ſomewhat leſs than a fourth part of its diameter. Hence ariſes a method of drawing anamorphoſes, i. e. wild, deformed figures, on a plane, which appear beautiful and well proportioned, when viewed in a cylindrical *mirror*.

MIRRORS, *for elliptic*, *parabolic*, *conic*, and *pyramidal*, we are not much acquainted with their properties: only that, in the firſt, if a ray ſtrike on it from one of its foci, it

it is reflected into the other; so that a lighted candle being placed in one, its light will be collected in the other. That the second, inasmuch as all the rays they reflect meet in one point, make the best burning-glasses of all others.

And, lastly, that wild, irregular figures, may be so drawn on a plane, as that, the eye being placed over the axis of the two last, they shall appear beautiful, and well proportioned. See ANAMORPHOSIS.

MIROUETTE, in the *Manege*, is used for a DAPPLE-*bay*.

MIS, a particle prefixed to divers words, particularly law-terms; denoting some default or defect. As, in *misprision*; *misdemeanor*, *to misdemean*; *misdoers*, *to teach omnis*, &c.

MISANTHROPY, *misanthropia*, formed of *μισεω*, *hatred*, and *ανθρωπος*, *a man*, a general dislike or aversion to man, and mankind. In which sense it stands opposed to *philanthropy*, or the love of mankind.

MISAVENTURE, or MISADVENTURE, *homicide by*, in *Law*, is where a man, doing a lawful act, without any intention of hurt, unfortunately kills another: as where a man is at work with a hatchet, and the head of it flies off and kills a standerby; or, where a person qualified to keep a gun, is shooting at a mark, and undesignedly kills a man; for the act is lawful, and the effect is merely accidental.

In the case of *misadventure*, the law presumes negligence, or at least a want of sufficient caution in him who was so unfortunate as to commit it; who, therefore, is not altogether faultless. The penalty inflicted by our laws is said by Sir Edward Coke to have been anciently no less than death; though others affirm, with greater reason, that it consisted in a forfeiture, as some say, of all the goods and chattels; according to others, of only part of them, by way of fine or weregild; which was probably disposed of, as in France, for pious uses, or for the benefit of the soul of the deceased. However the delinquent has now, and has had as early as our records will reach, a pardon, and writ of restitution of his goods as a matter of course and right, only paying for suing out the same; and, to prevent this expence, in cases where the death has notoriously happened by *misadventure*, or in self-defence, the judges will usually permit, if not direct, a general verdict of acquittal. See HOMICIDE.

Staundford distinguishes between *misadventure* and *misfortune*. The first he makes to be mere chance: as if a man, being upon or near the water, be taken with some sudden sickness, and so fall in, and be drowned; or into the fire, and be burnt.

Misfortune, according to him, is when a man comes to his death by some outward violence; as the fall of a tree, the running of a cart-wheel, the stroke of a horse, or the like.

MISCARRIAGE. See ABORTION; and for the method of preventing, see PREGNANCY.

MISCHIEF, *malicious*, or *damage*, in *Law*, is a species of injury to private property, which the law considers as a public crime. This is such as is done, not *animo furandi*, or with an intent of gaining by another's loss; but either out of a spirit of wanton cruelty, or diabolical revenge. Any damage arising from this mischievous disposition, though only a trespass at common law, is now by a multitude of statutes made penal in the highest degree. 22 Hen. VIII. c. 11. 43 *Eliz.* c. 13. 22 & 23 Car. II. c. 7. 1 Ann. stat. 2. c. 9. & 4 Geo. I. c. 12. 12 Ann. c. 18. 1 Geo. I. c. 48. 6 Geo. I. c. 23. 9 Geo. I. c. 22. See BLACK *act*. 6 Geo. II. c. 37. 10 Geo. II. c. 32. 28 Geo. II. c. 19. 6 Geo. III. c. 36 & 48. See FELONY.

MISCHNA, or MISNA, from שנה, *iteravit*, a part of the Jewish TALMUD.

The *Mischna* contains the text; and the gemara, which is the second part of the Talmud, contains the commentaries; so that the Gemara is, as it were, a glossary on the *Mischna*.

The *Mischna* consists of various traditions of the Jews, and of explanations of several passages of scripture: these traditions, serving as an explication of the written law, and supplement to it, are said to have been delivered to Moses during the time of his abode on the Mount; which he afterwards communicated to Aaron, Eleazer, and his servant Joshua. By these they were transmitted to the seventy elders, by them to the prophets, who communicated them to the men of the great sanhedrim, from whom the wise men of Jerusalem and Babylon received them. According to Prideaux's account, they passed from Jeremiah to Baruch, from him to Ezra, and from Ezra to the men of the great synagogue, the last of whom was Simon the Just; who delivered them to Antigonus of Socho; and from him they came down in regular succession to Simeon, who took our Saviour in his arms; Gamaliel, at whose feet Paul was educated, and last of all to Rabbi Judah the Holy, who committed them to writing in the *Mischna*. But Dr. Prideaux rejecting this Jewish fiction, observes, that after the death of Simon the Just, about two hundred and ninety-two years before Christ, the *Misphetical* doctors arose, who, by their comments and conclusions, added to the number of those traditions, which had been received and allowed by Ezra, and the men of the great synagogue; so that towards the middle of the second century, after Christ, under the empire of Antoninus Pius, it was found necessary to commit these traditions to writing; more especially as their country had considerably suffered under Adrian, and many of their schools had been dissolved, and their learned men cut off; and, therefore, the usual method of preserving their traditions had failed. Rabbi Judah, on this occasion, being rector of the school at Tiberias, and president of the sanhedrim in that place, undertook the work, and compiled it in six books, each consisting of several tracts, which altogether make up the number of sixty-three. Prid. Connect. vol. ii. p. 408, &c. ed. 9. This learned author computes that the *Mischna* was composed about the 150th year of our Lord; but Dr. Lightfoot says, that Rabbi Judah compiled the *Mischna* about the year of Christ 190, in the latter end of the reign of Commodus; or, as some compute, in the year of Christ 220. Dr. Lardner is of opinion that this work could not have been finished before the year 190, or later. Collect. of Jewish and Heathen Testimonies, &c. vol. i. p. 178. Thus the book called the *Mischna* was formed; a book which the Jews have generally received with the greatest veneration. The original has been published, with a Latin translation, by Surenhusius, with notes of his own, and others from the learned Maimonides, &c. in 6 vols. fol. Amstelod. A. D. 1698—1703. See TALMUD.

It is written in a much purer style, and is not near so full of dreams and visions as the GEMARA.

MISCONTINUANCE, in *Law*, the same with DISCONTINUANCE.

MISDEMEANOUR, an offence, or fault, particularly when in the execution of an office.

A crime, or *misdemeanour*, says judge Blackstone, is an act committed, or omitted, in violation of a public law, either forbidding or commanding it. This general definition comprehends both CRIMES and *misdemeanours*; which, properly speaking, are mere synonymous terms: though, in common usage, the word *crimes* is made to denote such offences as are of a deeper and more atrocious dye; while smaller faults, and omissions of less consequence, are comprized under the gentler name of *misdemeanours* only.

High crimes and misdemeanours denote offences of a heinous nature, next to high treason.

MISE, a French term, literally denoting expence, or disbursement: it is used in our law-books in divers acceptions. Sometimes for the profits of lands; sometimes for taxes, or tallages; and sometimes for expences, or costs: as, *pro misis & custagiis*, for costs and charges in the entries of judgments, &c.

MISE more peculiarly denotes an honorary gift, or customary present, where with the people of Wales used to salute every new king and prince of Wales, at their entrance upon the principality.

Anciently, the *mise* was given in cattle, wine, corn, &c. for the support of the prince's family; but when that dominion was annexed to the English crown, the gift was changed into money. The county of Flint paid two thousand marks, &c. for their *mise*.

The county of Chester also a *mise* or tribute of five thousand marks at the change of every owner of the said earldom, for enjoying the privileges of that palatinate. At Chester they have a *mise*-book, wherein every town and village in the county is rated what to pay towards the *mise*.

MISE is also used in speaking of a writ of right. What in other actions is called an *issue*, in a writ of right is called a *mise* or *mese*. So that *to join the mise upon the mere*, is as much as to say, to join issue on the meer right; i. e. to join upon this point, whether has the more right, the tenant or demandant.

Yet even in a writ of right, if a collateral point be tried, it is there called an *issue*, not a *mise*.

MISE is also sometimes used corruptly for *mease*, a messuage or tenement.

In some manors, a *mise* or *mease* place is taken for such a messuage or tenement as yields the lord an heriot at the death of the tenant.

MISEN, MIZEN, or MIZEN, in a *Ship*, denotes either the mast, or sail of that name; but at sea, they always mean the sail when the word *mizen* is used.

This is the hindmost of the fixed sails of a ship, extended sometimes by a gaff, and sometimes by a yard, which crosses the mast obliquely; the fore-end reaching almost

down to the deck, and the after-end being peeked up as high above the middle of the yard, where it is attached to the mast. The figure of the *mizen* is a trapezium, or parallelogram, one of whose corners is cut off by a diagonal, extended from one of its sides to the opposite corner, which becomes the peek of the *mizen*. Some great ships require two *mizens*; in which case that next the main-mast is called the *main-mizen*, and that next the poop the *bonaventure-mizen*.

The use of the *mizen* is, to keep the ship close to a wind; wherefore if a ship is apt too gripe too much, they use no *mizen*. But it is often used when a ship rides at anchor, to back her a-stern; so that she may not foul her anchor, on the turning of the tide; and sometimes a ship lies a-try with her *mizen* only.

MIZEN-*mast* is the mast upon which the *mizen* and its top-sail and slay-sails are supported, besides other sails, which are set occasionally, as the driver, ring-tail, &c. See *Talk. Ship. fig.* 1. *n.* 1. 13. 19. and MAST.

MIZEN, *change the*, is an order to bring the *mizen-yard* over to the other side of the mast. *Peak the mizen*, i. e. put the *mizen* right up and down the mast.

MIZEN, *sit to*, at Sea, the word of command to fit the *mizen-sail* right as it should stand. *Spell the mizen*, i. e. let go the sheet, and peek it up.

MIZEN-*sloop*, in a *Ship*. See STAY.

MIZEN-*yard*, in a *Ship*. See YARD.

MISERERE, *have mercy*, the name, and first word, of one of the penitential psalms; being that commonly given by the ordinary to such condemned malefactors as are allowed the benefit of the clergy: whence it is also called the *psalm of mercy*.

MISERERE *mei*, denotes a kind of COLIC, or disorder of the intestines, wherein the excrements, instead of passing off the common way, are often thrown up by the mouth. The *miserere mei* is the same with what we otherwise call *volvulus*, and ILIAC *passion*.

MISERICORDIA, *mercy*, in *Law*, an arbitrary amerciament, or punishment imposed on any person for an offence.

Where the plaintiff or defendant in any action is amerced, the entry is always *eat in misericordia*.

It is thus called, according to Fitzherbert, because it ought to be but small, and less than the offence, according to the tenor of Magna Charta.

Mulcta levior sit dicta, quæ levissima imponitur misericordia; gravissima enim mulctas hinc trahunt, miserissimas, redemptiones. See FINE, and REDEMPTION.

Hence, if a man be unreasonably amerced in a court not of record, as a court-baron, &c. there is a writ called *monstravit misericordia*, directed to the lord, or his bailiff, commanding them to take moderate amerciaments.

MISERICORDIA *communis*, is when a fine is set on the whole county, or hundred.

MISERICORDIA *in ebis & potu*, in our *Old Writers*, is used for any gratuitous portion of meat and drink, given to the religious in convents beyond their ordinary allowance. Matt. Paris. And in some convents they had a stated allowance of these over-commons upon extraordinary days, which were called *misericordiæ regulares*.

MISFEASANCE, in *Law*, a misdeed or trespass. Whence also *misfeasor*, a trespasser.

MISGUM, in *Ichthyology*, the name of a fish of the anguilliform kind, but broader and flatter than the eel, and of much the same size from the head to the tail; it has five black lines, one on the back, two, which are somewhat broader, in the middle of the sides, and two others, which are narrower lower down; these are all extended from the head to the tail; the intermediate spaces, and the belly, are of a somewhat bluish white, dotted with black spots; the fins are also spotted in the same manner; the mouth is small and round, like that of the lamprey, and is surrounded with beards, six on the upper jaw, and four on the under; and there are two other very slender ones near the nostrils; the eyes are small; the gills four on a side; and beside the back-fin there are four, two near the gills, and two lower on the body. This is a common fish about the German shores, and is esteemed a very delicate one at the table; it lays its spawn in March, and is in best season for eating in January and February. It is caught principally in standing and muddy waters; and it is said, that when out of water, it makes a sort of hissing noise.

MISKERING, *misberving*. See ARISHERING.

MISLETOE. See MISTLETOE.

MISNA. See MISCHNA.

MISNOMER, compounded of *mis*, which in composition signifies *amiss*, and *nomer*, *to name*, in *Law*, a wrong name, or the using of one name for another.

A *misnomer* sometimes one of the principal pleas in ABATEMENT.

MISPRISION, derived from the old French *mespris*, a *neglect* or *contempt*, in *Law*, signifies a neglect or overlight, and is generally used to denote all such high offences as are under the degree of capital, but nearly bordering upon them.

Misprisions are generally divided into two sorts; negative, which consist in the concealment of something which ought to be revealed; and positive, which consist in the commission of something which ought not to be done.

MISPRISION *of clerks*, is a neglect of clerks, in writing, or keeping records.

By the *misprision of clerks*, no process shall be annulled, or discontinued. And justices of assize shall amend the defaults of clerks mis-spelling of a syllable, or letter, in writing.

MISPRISION *of felony*, which is the concealment of a felony which a man knows, but never assented to, is punishable, in a public officer, by fine at. Westm. 1. 3 Ed. I. c. 9 with imprisonment for a year and a day; in a common person, with imprisonment for a less discretionary time; and in both with fine and ransom at the king's pleasure, declared by the judges in his courts of justice. Justices of the common pleas have a power to assess any amerciaments upon persons offending by *misprisions*, contempts, or neglects, for not doing, or misdoing, any thing, in or concerning fines.

MISPRISION *of treason*, is a negligence, in not revealing treason, where a person knows it to be committed.

It is enacted by stat. 1 & 2 Ph. & Mar. c. 10. that a bare concealment of treason shall be only held a *misprision*; which concealment becomes criminal, if the party apprised of the treason does not, as soon as conveniently may be, reveal it to some judge of assize, or justice of the peace. Besides, the statute 13 Eliz. c. 2. enacts, that those who forge foreign coin, not current in this kingdom, their aiders, abettors, and procurers, shall all be guilty of *misprision* of treason. The punishment of *misprision* of treason is loss of the profits of lands, during life, forfeiture of goods, and imprisonment during life.

MISSA. See MASS.

MISSAL, *missale*, a mass-book, containing the several masses to be used on the several days, feasts, &c.

The Roman *missal* was first compiled by pope Gelasius, and afterwards reduced into better order by pope Gregory the Great; who called it the *book of sacraments*. Each diocese, and each order of religious, have their particular *missals*, accommodated to the festivals of the province, or of the order.

MISSELTOE. See MISTLETOE.

MISSEL-*bird*, in *Ornithology*, the common English name of the larger species of thrush, called also the *throstle*, and by authors the *turdus viscivorus major*. It is much larger than any other of the thrush-kind: its legs and feet are yellow; its head of a brownish lead colour; and its back, tail, and rump, of the same colour, with an admixture of yellow; but in the summer months it a little changes its colour, and becomes more grey, or of the colour of unripe pickled olives; its throat, breast, and belly, are all variegated with black spots; the middle of its belly whitish, and the upper part of its breast, and part of its sides, and the under-feathers of its tail, yellowish; its bill is shorter and thicker than that of other thrushes, and of a dusky colour, except the base of the lower mandible, which is yellow. It usually is seen on the top branches of tall oaks, elms, and other high trees, and sings very sweetly, and is the largest bird that has any melody in its note. It begins its song, sitting on the summit of a high tree, very early in the spring; often with the new year, in blowing showery weather, whence it is called in Hampshire the storm-cock; the note of anger or fear is very harsh, between a chatter and shriek. It remains the whole year with us, flies singly, except with its female, and drives all the lesser species of thrushes from it. It is the best of all the kind for the table.

MISSEN-*mast*, or MIZEN-*mast*. See MIZEN.

MISSEN-*sail*. See MIZEN.

MISSILIA, among the Romans, a name given to largesses, thrown among the people on occasion of games and shews, such as small gold or silver coins, sweetmeats, and sometimes animals, as sheep, oxen, deer, &c. which were let loose to be carried off by the people.

The word comes from *mittere*, *to throw or let loose*.

MISSING-*wood*, a phrase used among *Bowlers*. See BOWLING.

MISSION, *missio*, among the Romans, a term used to signify the emperor's sending to rescue a wounded gladiator from his antagonist. The *munerarii*, or persons who exhibited the games, and likewise the people, used to rescue a favourite gladiator. The manner of their signifying this favour, was *pollice premsa*, or with the thumb hid in the palm of the hand. However the gladiator was only saved for that time; whereas by the RUDIS he had a free discharge.

MISSION. See EMISSION, MANUMISSION, REMISSION, and TRANSMISSION.

MISSION, in *Theology*, denotes a power or commission to preach the Gospel. Jesus Christ gave his disciples their *mission* in these words, *Go and teach all nations*, &c.

The Romanists reproach the Protestants, that their ministers have no *mission*; as not being authorised in the exercise of their ministry, either by an uninterrupted succession from the apostles, or by miracles, or by any extraordinary proof of a vocation.

Many among us deny any other *mission* necessary for the ministry, than the talents necessary to discharge it.

MISSION is also used for an establishment of people zealous for the glory of God, and the salvation of souls; who go and preach the gospel in remote countries and among infidels.

There are *missions* in the East, as well as in the West Indies. Among the Romanists, the religious orders of St. Dominic, St. Francis, St. Augustine, and the Jesuits, have *missions* in the Levant, America, &c.

The Jesuits have also *missions* in China, and all other parts of the globe, where they have been able to penetrate. The Mendicants abound in *missions*.

There have been also several protestant *missions* for diffusing the light of Christianity through the benighted regions of Asia and America. Of this kind has been the Danish *mission*, planned by Frederic IV. in 1706. And the liberality of private benefactors in our own country has been also extended to the support of *missionaries* among the Indians in America, &c.

MISSION is also the name of a congregation of priests and laymen, instituted by Vincent de Paul, and confirmed in 1632, by pope Urban VIII. under the title of *Priests of the congregation of the Mission*.

These profess to make it their whole business to assist the poor people in the country; and to this purpose they oblige themselves never to preach, or administer any of the sacraments, in any town where there is an archbishop, bishop, or provincial, residing.

The priests of the *Mission* were also intrusted with the direction and government of a female order, called *Virgins of Love*, or *Daughters of* CHARITY, whose office it was to administer assistance and relief to indigent persons, who were confined to their beds by sickness and infirmity. This order was founded by a noble virgin, whose name was Louise le Gras, and received, in the year 1660, the approbation of pope Clement IX.

They are settled in most provinces of France, Italy, Germany, and in Poland. At Paris they have a seminary which they call the *Foreign Mission*, where youth are bred up and qualified for *missions* abroad.

MISSIONARY, an ecclesiastic who devotes himself and his labours to some *mission*, either for the instruction of the orthodox, the conviction of heretics, or the conversion of infidels. See JESUITS.

MISSIVE, something sent to another. From the Latin *mitto*, *I send*.

We say *missive* letters, or letters *missive*, meaning letters sent from one to another.

In propriety, *letters missive* are letters of business, but not business of great concern; in contradistinction from letters of gallantry, letters on points of learning, dispatches, &c. See LETTERS.

MIST, a meteor, called also FOG.

The bluish *mist* which we sometimes see on our fields and pastures in a morning, though often innocent, yet has been in some places found to be the actual cause of murrain, and other fatal diseases among the horned cattle. Dr. Winklar gives, in the Philosophical Transactions, an account of a murrain affecting the cattle in Italy and other places, which was evidently seen to spread itself over the countries in form of a blue *mist*. Wherever this was perceived, the cattle were sure to come home sick; they appeared dull and heavy, and refused their food; and many of them would die in four and twenty hours. Upon dissection there were found large and corrupted spleens, sphacelous and corroded tongues; and in some places those people who were not careful of themselves in their management of their cattle, were infected and died as fast themselves. The principal cause of this disease seems to be the exhalation of some unwholesome steams from the earth; and it was observable, that there had been three earthquakes in Italy the year before it happened.

The method of cure which succeeded best, was this: as soon as any beast appeared to be sick, they examined the tongue, and if aphthæ or little blisters were found on it, they scraped it with a silver instrument made with sharp teeth at the sides, till it bled in all those parts where the aphthæ were; the blood was then wiped away with a cloth, and the whole tongue washed several times with vinegar and salt. After this the following medicine was given internally: take of soot, brimstone, gunpowder, and salt, of each equal parts: mix these in as much water as will make a mixture thin enough to be swallowed, and let a spoonful be given for a dose three or four times a day. The cattle which were in health had this medicine given them, as well as the sick; and the consequence was, that very few died in Switzerland, while almost all died in other places.

It was very remarkable that this contagion, on this occasion, seemed to travel slowly and regularly on: it came at the rate of about two German miles in twenty-four hours: this it kept regularly to during the whole time of its raging, and never appeared in very distant places at the same time.

The whole surface of the earth emitting these effluvia, no cattle escaped them in the course of their way, but those which were kept within doors at rack and manger fell ill at the same time, and in the same manner with those in the open fields.

Dr. Slare was of opinion, that it was owing to certain insects, which could not fly faster than at the rate of two German miles a day; and that they travelled regularly, and spread the mischief where they passed; but there wanted some judicious persons, versed in these observations, to have examined both the state of the air, and the beasts, on this occasion. Phil. Trans. N° 145.

MISTLETOE, MISLETOE, or MISSELTOE, *viscum*, in *Botany*, a genus of the *dioecia triandria* class: it has male and female flowers upon separate plants; the male flowers have an empalement composed of four oblong leaves, and no petals, but have four summits, which are oblong and acute pointed, fastened to the leaves of the empalement; the female flowers have an empalement of four small oval leaves sitting upon the germen, but have no petals or stamina; with an oblong three cornered germen, situated under the flower, having no style, but crowned by an obtuse stigma; the germen afterwards turns to a globular smooth berry with one cell, including a fleshy heart-shaped seed. Linnæus enumerates six species. We have but one species of this genus in Europe, which is the *mistletoe* with white berries, a plant of the parasite kind, growing, not on the ground, but on other trees, as the oak, apple-tree, pear-tree, white-thorn, ash, lime, willow, elm, &c. Miller's Gard. Dict.

Mistletoe grows to the height of about two feet. It consists of several stems, which are usually covered with a greenish, sometimes a yellowish bark, and are about the thickness of the finger, hard, woody, and divided by knots; from which spring the leaves, which grow by two and two, opposite to each other; they are oblong, thick, of a greenish or yellowish colour, veined their whole length, and rounded at the end. Its flowers grow by three and three, trefoil-wise, at the extremes of the branches: each flower is a sort of yellow calyx, one third of an inch in diameter, divided into four parts.

The fruit likewise grows by three and three, at the extremes of the branches; they are a kind of white, roundish berries, not unlike pearls, containing a flattish seed, in form of an heart, covered with a fine silvered membrane, and environed with a viscid, glutinous humour, of a whitish colour, wherein the seed naturally buds or germinates, and puts forth two eyes. From this juice it is, that the Latins denominate the plant *viscum*. The fruit grows on different branches from the flowers. The uncommon sort whereon the *mistletoe* grows has occasioned abundance of fabulous notions, both as to its production and virtues.

Pliny, and most naturalists, relate, that thrushes, being exceeding fond of the berries of the *mistletoe*, swallow them, and cast them out again on the branches of trees where they use to perch; and, by this means, give occasion to a new production of *mistletoe*. Hence that proverb, *Turdus sibi cacat malum*; the *viscum* being sometimes used as bird-lime. By cracking the berries, also, with their bills, or claws, they are supposed to let out the viscous juice, which facilitates their sticking.

It has been formerly supposed that the *mistletoe* was produced as a sort of excrescence from the tree on which it is found; but time and experiments have shewn, that it is raised like other plants from seeds. Its berries are of a viscous nature, and sticking to the beaks of birds that eat them, they may be rubbed off against the branches of other trees, and there take root and grow; but this is not necessary for their propagation, for the great numbers of plants of it, usually found on the same trees, seem to prove very plainly, that it is produced by the falling of its seeds, like all other plants, but that the matrix for these is not earth, but the branches of a living tree.

The trees on which *mistletoe* is principally found, are the apple, the ash, and other smooth rinded ones, such as the white thorn, the crab, the hazle, and maple. It is very rarely found upon the oak; and though it may easily be propagated by its seeds on other trees, yet it has not been found to take readily upon the oak. However the

mistletoe,

miſſletoe of the laſt has been always accounted the beſt, which opinion, as Mr. Ray obſerves, may be owing to the ſuperſtitious honour paid by the ancient Druids to the oak.

When a berry of *miſſletoe* is cruſhed and broken againſt the bark of a tree, the viſcous matter which ſurrounds the ſeed ſoon dries away into a thick and tough ſkin, which ſurrounds the ſeed, and keeps it faſt down to the bark; but the rains frequently waſh theſe off afterwards, eſpecially when they have fallen upon the ſmoother part or the bark, or upon ſuch parts of a tree as are clean and free from moſs. And hence it is, that moſt of the *miſſletoe* we find, is either found upon the under part of the branch of a tree from whence the rain could not ſo eaſily diſlodge it, or on ſuch as have a rough bark, or are in part covered with the common tree-moſſes.

Mr. Du Hamel, determined to inveſtigate the nature of this odd plant, put ſeveral of the ſeeds of it into ſmall ſlits, which he cut in the barks of different trees, by that means to defend them from being waſhed away by rains, and theſe all ſucceeded well and ſhot, except thoſe he planted on the fig, on which he made ſeveral unſucceſsful attempts; the miſchief done to the ſeeds by the milky juice of this tree was probably the cauſe of this. It is no wonder that *miſſletoe* grows equally on all ſorts of trees, ſince there requires no more to make it grow than the effect of the rains and night dews; and this author found the ſeeds ſhooting on earthen pots and ſtones, which he kept ſhaded from the heat of the ſun; and from parallel experiments it ſhould ſeem alſo, that the tranſpiration of trees helps greatly the germination of theſe ſeeds.

The ſeeds of *miſſletoe* town, if we may ſo call it, on the bark of trees in February, begin to ſhoot in June, and at that time there are ſeen two little round bodies iſſuing out at the two angles of the triangular ſeeds; but as theſe ſeeds are ſubject to ſome irregularities in their figure, ſo they alſo are in their germination, for from the oval ſeeds there is only one ſhoot, and from thoſe which are irregularly angular, there are ſometimes four or five.

Each of theſe round bodies is faſtened to a pedicle, which has its inſertion in the fleſhy part of the ſeed, in which there is a ſort of grooves, which make it ſeem as if theſe pedicles came out of a ſort of caſe.

This ſort of germination is peculiar to *miſſletoe*, no other ſeed ſhooting out ſo many radicles.

The length of theſe radicles is in a great meaſure owing to the poſition of the ſeed on the branch of the tree, for they always grow in length till they reach the bark.

It is to be obſerved alſo, in regard to the germination of theſe ſeeds, that they are the only ones in which the radicle takes indifferently any direction, in all other ſeeds it points ever downwards only. The ſeeds of *miſſletoe* will ſhoot equally well on the upper and under ſides of a branch of a tree, and thoſe on the upper will bend their radicles downward, while thoſe on the under will ſtrike theirs directly upward with the ſame eaſe.

The radicles of *miſſletoe* are, as has been already obſerved, compoſed of a little round body, ſuſtained by a pedicle. When this pedicle has grown to ſuch a length that the round body touches the bark, it opens before into the ſhape of the trunks of flies, and other inſects, and by this means touching cloſely at all its edges, it becomes faſtened extremely firm to the tree. From this reſemblance in ſhape to the trunks of ſmall animals, M. Du Hamel calls theſe radicles the trunks of the ſeed of *miſſletoe*. The ends of theſe trunks of the radicles are alſo faſtened to the bark of the tree by a viſcous matter, which, when the trunk is gently raiſed, is drawn out into ſtrings an all ſides to ſome length.

In the inner part of this trunk, or open button, there are two ſubſtances to be diſtinguiſhed; in the centre there is a white granulated matter, and round that a greenith one; both theſe are juicy, but the outer leſs ſo than the central white part; the outer one is plainly the ſame with the outer rind of the root of the *miſſletoe*, or the ſecond bark of its trunk. Theſe both very quickly adhere to the tree, ſtriking their ſeveral granuhe into it, and theſe furniſh afterwards the roots of the *miſſletoe*. The outward bark of *miſſletoe* is thin, of a deep green, and ſomewhat rough; it is ſtronger than that which it covers; and this is not extended to the roots of the plant, but ſpreads over the bark of the tree at the bottom of the ſtalk, juſt as the feet of the corals and other ſea plants do over ſtones. The viſcous matter, by which the trunk adheres to the tree, is furniſhed from all parts of the radicle, but principally from its outer bark, and is not at all owing to the juices of the tree, ſince it is found as abundantly on thoſe radicles which have been made to adhere to ſtones, as on thoſe which have been on trees. A little time fixes theſe trunks very firmly; but it is obſervable, that though the outer bark or edge of theſe open balls adheres equally all round to the bark of the tree, the granulæ of the inner ſubſtance always direct themſelves to and inſinuate in the little cleſts or cracks of the rind of the tree. While the ſeeds of *miſſletoe* are in this ſtate, they may be tranſplanted to other places, and ſet on other trees, and ſeldom fail to thrive.

Seeds of this plant may be made to ſhoot on ſtones, and will fix their trunks to them, but here they naturally ſoon periſh; they may however be removed from theſe ſtones to the branches of trees, as ſoon as they have affixed themſelves, and being then in a ſtate of drawing nouriſhment, they will affix themſelves to the tree, and from its juices begin to thrive immediately.

It has been very naturally ſuppoſed by thoſe who thought the *miſſletoe* no perfect plant, that it had no roots, nay even thoſe who allowed it to be a perfect plant, and producible from ſeeds, yet have ſuppoſed it had no root. Malpighi, however, affirms that he plainly ſaw the root. And Tournefort countenances the ſame opinion; but neither of theſe authors hath perfectly deſcribed them.

In that part of the branch of a tree where the *miſſletoe* grows, there is always obſerved a thickneſs, and the bark is always chopped in ſeveral places; but the roots of the *miſſletoe* are by no means to be ſeen externally, being hid both by the bark of the tree, and by the expanſion of the bark of the plant itſelf at its bottom. It is neceſſary, therefore, for the diſcovery of the roots, to raiſe very nicely both the bark of the plant, and that of the tree; but the hardneſs of theſe barks, and their ſtrict attachment to the roots, make this difficult; and there is indeed no way of ſucceeding well in the attempt, but by boiling the part in water, and making nice diſſections of it before it is cold.

It has been ſuppoſed by many, that the roots of the *miſſletoe* penetrated the woody ſubſtance of the tree; but though appearances make greatly for this ſyſtem, it is by no means true in fact. The roots of the young plants, when they have penetrated through all the laminæ of the bark, and reach the wood, turn off, as the roots of plants do which meet with ſtones, &c. in their paſſage, and ſpread horizontally between the inner bark and wood, or elſe re-aſcend the bark, the looſe and juicy nature of which is much fitter for affording them nouriſhment than the hard ſubſtance of the wood.

There are alſo found always a multitude of woody excreſcenſes, like warts and wens, about the place where the *miſſletoe* grows; theſe are formed like the woody galls produced on trees by the punctures of inſects, by an extravaſation of the woody juices. Theſe make the ſwelling about that part of the branch where the *miſſletoe* grows, and, as they become woody, and ſwell about the roots, ſerve to cover them with hard wood, which they never penetrated. Theſe make it probable enough that the roots of *miſſletoe* never penetrate hard wood; but what proves it much more evidently, is, that if the branches of trees full of *miſſletoe* plants be cut and ſplit in different directions, juſt at the place of the inſertion of the plant, the ſeveral annular circles of the wood within are found perfect, regular, and in their natural ſtate, ſo far as the branch was formed at the time the *miſſletoe* took root upon it; theſe ſhew the age of the branch at that time, but above theſe there are always ſeveral other laminæ, which are what have been formed ſince the time of the *miſſletoe*'s growing there; and thoſe which have been formed out of the inner laminæ of the bark, in which the roots of *miſſletoe* had made many wounds and great extravaſations of the juices, are found, though woody, full of the roots of the plant, and are very irregular, and full of the tubera which thoſe extravaſions occaſion, by no means appearing like the annular circles of the wood formed before. The ligneous fibres in the outer, or ſince formed wood, are laid in very irregular directions, and the roots of the *miſſletoe* may be eaſily diſtinguiſhed among them by their colour.

The *miſſletoe*, as the bark in which its roots were ſpread, hardened into wood, would be in the ſtate of a tree, planted in an earth which, by degrees, petrified about it, and muſt periſh; but nature has provided for it in this caſe; for as theſe roots are impriſoned in wood, and a new bark is formed by the ſap of the tree, the trunk of the *miſſletoe* ſends out a new ſeries of roots, which ſpread through this in like manner; ſo that though a plant of *miſſletoe* has ever ſo many ſeries of its roots embodied in the hard wood, from which it can have no nouriſhment, it has alſo ſome, ſufficient for its ſupport, ſpread in its new-formed bark.

Another thing very remarkable in thoſe plants of *miſſletoe*, many of the roots of which are lodged in the hard wood, is, that the roots diffuſed through the bark have often a large tubercle at their ends, which probably is furniſhed with numerous openings for receiving the juices by which the plant is to be nouriſhed, and ſerves in the place of many roots.

There are sometimes indeed found plants of *mistletoe* which live wholly by the nourishment they receive from the wood; these are in the state of grafts of common fruit-trees; but they are rare, and it very seldom succeeds when the *mistletoe* is attempted to be propagated by the common method of grafting, though the plants of *mistletoe* may very easily be grafted, by approach, into one another.

Though this plant is evidently propagated by its seeds, yet it also propagates itself very often by suckers, and it is not uncommon to find young shoots at a finger's breadth or two from the old one. The gardeners, who value their trees, are very careful to destroy the *mistletoe* from them, and that very properly, since it is extremely obvious from what has been observed, that it robs the tree it grows on of a great deal of its nutritious juice. The common method of cutting off the plants to this purpose, is, however, by no means sufficient; for the old stock frequently pushes out new shoots, and the roots afford suckers, so that the case becomes worse than before. There is indeed no way of destroying it, but by the cutting away with it a part of the tubercle it forms on the branch where it grows.

The roots of *mistletoe*, while young, are green, very tender, and granulated, as is also the bark of the older ones; but these have a woody filament within. They are not regularly round, but are often flat, and usually adapted in their shape to the place where they are lodged; and about their insertions it is not unfrequent to see a sort of elongation of their bark, which blends itself with the bark of the tree on which they grow.

The progress of the branches of *mistletoe* is much slower than that of the roots. The first year, and often the second, is spent wholly on their part, in raising themselves into an erect posture, and very often this operation proves fatal to them.

It is a very singular circumstance in this plant, that its seeds produce singly several young plants. No other vegetable has this property. It is true, indeed, that two young barrels have been seen to rise from the same nut; but then we know very well, that nuts have frequently double kernels in the same shell; but here the seed is contained singly in a berry, and, to all examination, appears of a simple uniform structure, though it doubtless is composed according to the number of young plants it will produce, of three, four, or more perfect seeds.

When the young plant of the *mistletoe* seed has freed itself from the husk at its end, and raised itself upright, it is found terminated at the end by a sort of button, like that of other young shoots, which contain the leaves. This button stands, however unaltered all the first year, and sometimes all the second; in the spring following there appear from the button two leaves, and in the axe of these leaves there are seen two other buttons; and afterwards there issue from these buttons branches, terminated usually by two, but sometimes by three leaves. These are the produce of the third or fourth year; all the succeeding years there are new buttons formed in the axe of the leaves, and the branches from these expand themselves so regularly, that very frequently the whole shrub is of a regularly round figure.

The old leaves become yellow, and fall off, and there come no new ones in their places, so that the old stalk, and consequently the whole inner part of the plant, is naked, and the leaves are only found on the circumference growing out the young branches.

It is a remarkable observation, that every button of the *mistletoe* contains the rudiments of three young branches, and hence every knot ought to be furnished with six branches; and this would ever be the case, but that several of the young branches die either before or soon after their emerging from the button.

Mistletoe will grow on all kinds of trees; but it does not grow on all with the same strength and vigour. The pear, the apple, the white thorn, and the lime, are trees it grows on very successfully. The oak, the hazel, and the juniper, are very starving for it. Mr. Du Hamel could never make it succeed by sowing on the bark of these trees; but it has sometimes been found naturally propagated on it, though in a starving condition. It will also grow on annual plants, but on these it never can come to any height, as their stalks perishing at the approach of winter, the *mistletoe* perishes with them. Mr. Du Hamel took great pains to sow and try to raise it on the ground, and succeeded so well as to make the seeds shoot, and their radicles grow to some length; but finding no proper hold to fix themselves upon, they all perished; whence it seems that this is absolutely a parasitical shrub, and can grow no where but on some other tree. Mem. Acad. Par. 1749.

As for the virtues of *mistletoe*, it seems of the most efficacy in the epilepsy; against which some will have it a specific. Dr. Colbatch has wrote expressly to prove it such. It has been also prescribed in apoplexies, lethargies, and vertigoes; and worn about the necks of children, to prevent convulsions, and ease the cutting of their teeth. However the leaves and branches of *mistletoe*, though formerly recommended as specifics in convulsive and other nervous disorders, are now fallen into general neglect, and do not appear to have any considerable medicinal power. Half a dram or a dram of the wood or leaves in substance, or an infusion of half an ounce, the doses commonly prescribed, have no sensible effect.

The virtues ascribed to the *mistletoe* may, perhaps, be the remains of the religious honours paid it by the ancient Gauls; among whom the Druids assembled constantly on the first day of the year, went in quest thereof with hymns and other ceremonies and rejoicings, distributing it again among the people, as a thing sacred; after having first consecrated it, crying *Au gui l'an neuf*, to proclaim the new year.

This cry is still kept up at Picardy, where they add *planten*, to wish a plentiful new year.

M. Perrault observes, that the *mistletoe* is full of a disagreeable juice, which weakens the tree whereon it grows; and that the fruit has always a disagreeable taste while it sticks on it.

MISUSER, in our *Old Writers*, an abuse of any liberty or benefit: as he shall make fine for his *misuser*. Old Nat. Br. 149.

By misuser, a charter of a corporation may be forfeited; so also an office, &c.

MISY, in *Natural History*, the name of a fossile substance, used very frequently by the ancients in medicine, and supposed to be one of their now lost medicines, but erroneously; it being still very common in the Turkish dominions, and not unfrequently found in the mines at Cremnitz in Hungary. It is a considerably firm substance, though of an irregular and seemingly not compact texture, and much resembles some of our gaudy marcasites; but that it wants their hardness and their weight, and is not inflammable.

It is at present no where put to any use. The ancients esteemed it of the same nature with the CHALCITIS, but that it possessed those virtues in a more remiss degree; they had it from Ægypt and Cyprus, and used it externally in hemorrhages, and some cutaneous eruptions.

MISY, in *History*, a name given by Theophrastus, and all the old Greek writers, to a kind of truffle or subterraneum mushroom, of a very delicate flavour. The truffles of Numidia, and some other parts of Africa, were always esteemed superior to those of any other part of the world. They are called *terfes*, *cumbi*, or *lomæ*, by some later writers, and were brought to Rome, and so greatly esteemed, that no dish was ranked above them. These were called Lybian truffles by the Romans, and they seem to have been the same with the Cyrenean *misy* of the Greeks. It is to be observed, that the Greeks in general, in early times, were very little acquainted with the affairs of Africa; and all that they had from this part of the world, was said to come from Cyrene, some old cities of their forefathers being there, and keeping up a friendship and trassic with them. The *thyon*, a tree growing plentifully in almost all parts of Africa, and which is the same with the citrus of the Romans, was in this manner attributed to Cyrene, by the same Theophrastus. And thus, when speaking of truffles, he adds, that the Cyrenean *misy* surpassed all the other kinds in flavour; his words haud at large in Athenæus; and thence Pliny has taken his account, which he closes in this manner: "The thing which they call *misy*, in the province of "Cyrene, is of this kind; but it is more fleshy and of "a finer taste and smell." This is the sense of Pliny, as the text stands in our copies; but it is probable that he translated Theophrastus better than they, as least as we know that what he says is not his own, but taken from that author, we have a right to understand it in his way, and that is, that the roots of this Cyrenean *misy* have a delicate smell resembling that of meat, or fish newly cut. Pliny, lib. xix. cap. 3.

It is very certain, that this Cyrenean *misy* of the old Greeks is the same thing with the delicate African truffle or terfez of Leo Africanus, and the moderns; and Pliny had read some of the ancients who were sensible of this, and had taken from them an account that the African truffles are the finest in the world; and yet did not perceive, that these African truffles were the same with the Cyrenean *misy*, which he immediately after mentions from Theophrastus.

MITCHELLA, in *Botany*, a genus of the *tetrandria monogynia* class: with a single-petaled flower, four stigmas, and a bifid four-seeded berry. There is only one species.

MITCHELS, among *Builders*, are purbeck stones, from

fifteen inches square to two feet, squared and hewed ready for paving.

MITE, in *Natural History*, the name of a small animal, very well known and found in old cheese, and in many other bodies, both recent and petrified.

To the naked eye the *mites* in cheese appear like moving particles of duft, but the microscope discovers them to be perfect animals, having as regular a figure and performing all the functions of life as perfectly as creatures that exceed them many times in bulk. See *Tab. of Microscopical Objects, Plate* 1.

They are crustaceous animals, and are usually transparent; the principal parts of them are the head, the neck, and the body; the head is small in proportion to the body, and has a sharp snout, and a mouth that opens and shuts like a snake's: they have two small eyes, and are extremely quick-sighted; and when you have once touched them with a pin, you will easily perceive how cunningly they avoid a second touch.

They are of different sorts; for some of them have six legs, and others have eight; each leg has six joints surrounded with hairs, and two little claws at the extremity, with which it very nicely takes hold of any thing; the hinder part of the body is plump and bulky, and ends in an oval form, from which there issue out a few exceeding long hairs; other parts of the body and head are also beset with thin and long hairs.

The males and females are easily distinguished in these little animals. The females are oviparous, as the louse and spider, and from their eggs the young ones are hatched in their proper form, without having any change to undergo afterwards. They are however, when first hatched, extremely minute; and, in their growing to their full size, they cast their skins several times.

These little creatures may be kept alive many months between two concave glasses, and applied to the microscope at pleasure. They are thus often seen *in coitu*, conjoined tail to tail; and this is performed by an incredible swift motion.

Their eggs, in warm weather, hatch in twelve or fourteen days; but, in winter, they are much longer: these eggs are so small, that a regular computation shews, that ninety millions of them are not so large as a common pigeon's egg. Baker's Microscope, p. 18.

Mites are very voracious animals; they not only prey upon cheese, but on all sorts of dried flesh, fish, fruits, and seeds; and almost on all things which have some degree of moisture, without ever being wet; and they have often been seen to eat one another. Their manner of eating is by thrusting alternately one jaw forward and the other backward; and in this manner grinding their food; and after they have done feeding, they seem to chew the cud.

There are several other distinctions observable in the *mites*, which are found among different substances. Those in malt-dust and oat-meal are much smaller than the cheese-*mites*, and have more and longer hairs. The *mites* among figs resemble beetles, and have two feelers at the snout, and two very long horns over them; these have only six legs, and are more sluggish than those in malt-dust. Those found among figs have also very long hairs, and those beset at certain distances with other smaller hairs; whence Mr. Leeuwenhoek conjectures, that these longer and larger hairs are jointed at those places where the short ones are found.

There is a sort of wandering *mites*, found wherever there is any thing they can feed on; these are often found in form of a white dust, and are not suspected to be living creatures.

The *mite* is an animal very tenacious of life; it will live months without food; and Mr. Leeuwenhoek had one which lived eleven weeks on the point of a pin, on which he had fixed it for examining it by his microscope. Leeuwenhoek's Arcan. Nat. tom. ii. p. 368.

MITE, a small coin, formerly current; equal to about one third part of a farthing.

MITE also denotes a small weight used by the monicrs. It is equal to the twentieth part of a grain, and is divided into twenty-four droits.

MITELLA, in *Botany*. See SANICLE.

MITELLA, in *Surgery*, a name given to the scarf for suspending the arm when injured.

MITHRA, *feasts of*, in *Antiquity*, were feasts celebrated among the Romans in honour of *Mithra*, or the sun. The most ancient instance of this *Mithra*, among the Romans, occurs in an inscription dated in the third consulate of Trajan, or about the year of Christ, 101. This is the dedication of an altar to the sun, under the name of *Mithra, deo Soli Mithræ*. But the worship of *Mithra* was not known in Egypt and Syria in the time of Origen, who died about the year of Christ 263: though it was common at Rome for more than a century before this time. The worship of *Mithra* was proscribed at Rome in the year 378, by order of Gracchus, prefect of the prætorium. According to M. Freret, the feasts of *Mithra* were derived from Chaldea, where they had been instituted for celebrating the entrance of the sun into the sign Taurus.

MITHRAX, in *Natural History*, the name given by Pliny and the ancients, to a gem found in Persia, which when held up to the sun shewed many colours. It was probably no other than the OPAL. Hence the barbarous writers of the middle ages seem to have taken their account of the *mithridates*.

MITHRIDATE, MITHRIDATIUM, in *Pharmacy*, an antidote, or composition, in form of an ELECTUARY; serving either as a remedy, or a preservative against poisons.

Mithridate is one of the capital medicines in the apothecaries shops, being compounded of a vast number of drugs; among which are, *opium, myrrh, agaric, saffron, ginger, cinnamon, spikenard, frankincense, castor, pepper, gentian*, &c.

It is accounted a cordial, opiate, sudorific, and alexipharmic. Matthiolus says, it is more effectual against poison than Venice treacle, and much easier to be made.

It takes its name from its inventor, Mithridates, king of Pontus, who is reported to have so fortified his body against poisons, with antidotes and preservatives, that when he had a mind to dispatch himself, he could not find any poison that would take effect.

The receipt of it was found in his cabinet, written with his own hand, and was carried to Rome by Pompey. It was translated into verse by Damocrates, a famous physician, and hence called *confectio Damocratis*; and was afterwards translated by Galen, from whom we have it. It has undergone considerable alterations since the time of its royal prescriber.

MITHRIDATE *mustard*. See TREACLE *Mustard*.

MITHRIDATE, *mustard bastard*, is a species of IBERIS.

MITHRIDATES, in *Natural History*, the name of a stone found in some parts of Persia, seeming to be the same as the mithridax or mithrax.

MITHRIDAX, in *Natural History*, the name of a gem described by Solinus, to which he ascribes qualities the same with those given by Pliny to the MITHRAX; and therefore probably the same stone with it.

MITRALES *valvulæ*, MITRAL *valves*, in *Anatomy*, two valves in the HEART; thus called from their resembling the figure of a mitre.

They are placed at the orifice of the pulmonary vein, in the left ventricle of the heart. Their office is to close the orifice thereof, and to prevent the return of the blood through the pulmonary vein into the lungs again.

MITRE, MITRA, from Μιτρα, which signifies the same; a pontifical ornament, worn on the head by bishops, and certain abbots, on solemn occasions.

The *mitre* is a round cap, pointed, and cleft at top, with two pendants hanging down on the shoulders, and fringed at both ends. The bishop's is only surrounded with a fillet of gold, set with precious stones: the archbishop's issues out of a ducal CORONET. See *Tab.* III. *Heraldry, fig.* 121. These are never used otherwise than on their coats of arms. Abbots wear the *mitre* turned in profile, and bear the crosier inwards, to shew that they have no spiritual jurisdiction without their own cloisters.

The pope has also granted to some canons of cathedrals the privilege of wearing the *mitre*. The counts of Lyons are also said to have assisted at church in *mitres*.

In Germany, several great families bear the *mitre* for their crest; to shew that they are advocates, or feudatories, of ancient abbeys, or officers of bishops, &c.

The pope has four *mitres*, which are more or less rich, according to the solemnity of the feast-days they are to be worn on. The *mitre* was originally the women's headdress, as the hat was that of the men. This appears from Remulus in Virgil, who reproaches the Trojans, that they were dressed like women, and wore *mitres*.

Et tunicæ manicas, & habent redimicula mitræ.

The cardinals anciently wore *mitres*, before the hat, which was first granted them by the council of Lyons, in 1243. Authors make no mention of the *mitre* as an episcopal ornament, before the year 1000.

MITRE, in *Architecture*, is the workmen's term for an angle that is just 45 degrees, or half a right one.

If the angle be a quarter of a right angle, they call it a *half-mitre*.

To describe such angles, they have an instrument called the *mitre-square*; with this they strike *mitre-lines* on their quarters, or battens; and, for dispatch, they have a *mitre-box*, as they call it, which is made of two pieces of wood, each about an inch thick, one nailed upright on the edge of the other; the upper piece hath the *mitre-lines* struck upon it, on both sides, and a keel, to direct the saw in cutting the *mitre-joints* readily, by only applying the piece into this box.

MITRE is used by the writers of the Jewish history for a sort

of base money, which was very common there about the year 1280, and for many years before, and as many after. There were beside the *mites*, several other pieces called according to the figures impressed upon them, rotaries, hoodies, eagles, and by the like names. They were imported from France, and other countries, and were so much below the proper currency of the kingdom, that they were not worth so much as a half-penny each. They were at length decryed in the year 1300, and good coins struck in their place. These were the first Irish coins in which the sceptre was left out. They were struck in the reign of Edward, the son of our Henry the Third, and are still found among the other antiquities of that country. They have the king's head in a triangle full-faced. The penny, when well preserved, weighs twenty-two grains; the half-penny ten grains and a half.

MITRED *abbots*. See ABBOT.

MITTA, in our *Old Writers*, is an ancient Saxon measure. Its quantity is not certainly known; but it is said to be *mensura decem modiorum*, a measure of ten bushels. Domesday.

Mista or *mischa*, being besides a measure for salt and corn, is used for the place where the chaldrons were put to boil salt. *Chaldrones quoque ad sal conficiendum cum propriis fedibus mischæ vocantur.*

MITTENDARII, among the Romans, commissioners sent into the provinces by order of the *præfectus prætorii*, or captain of the guards, upon some public account, as to inspect the behaviour and management of provincial governors, and observe whatever was amiss; all which they were to lay before the prefect, who had authority to remedy such abuses.

MITTENDIS *recordo & processu*. See RECORDO.

MITTENDO *manuscriptum pedes finis*, in *Law*, a writ judicial, directed to the treasurer and chamberlains of the exchequer, to search for and transmit the foot of a fine, acknowledged before justices in eyre, into the commonpleas, &c.

MITTER *l'estate*, and *mitter le droit*. See RELEASE.

MITTIMUS, in Law, a writ by which records are ordered to be transferred from one court to another; sometimes immediately, as out of the king's bench into the exchequer; and sometimes by a certiorari into the chancery; and from thence, by a *mittimus*, into another court.

MITTIMUS is also used for a precept in writing, directed by a justice of peace to a gaoler, for the receiving and safe-keeping a felon, or other offender, by him committed to the gaol.

This is a warrant under the hand and seal of the justice, containing the cause of the commitment of the offender.

MITU, or MITU-PORANGU, in *Ornithology*, the name of a Brasilian bird of the pheasant-kind, according to Marggrave, and the generality of those who speak of it; but supposed by Mr. Ray rather to approach to the nature of the peacock or turkey-cock.

It is larger than the common English cock, and is all over the back, wings, &c. of a fine deep black; but on the belly of a partridge-brown; and has a series of fine glossy black feathers on its head, which it occasionally raises up in a sort of creft; its beak is very beautiful, broad at the base and narrow at the point, and of a fine bright red; its tail is very long, and it can at pleasure raise and expand it like the turkey. It is very easily tamed, and loves to roost on trees. Its flesh is very fine and delicate. See *Tab.* III. *of Birds*, N° 34.

MIXING *of mortar*. See MORTAR.

MIXT, or MIXT *body*, in *Philosophy*, is that which is compounded of divers elements or principles.

By which, *mixt* stands contradistinguished from *simple*, or *elementary*, which is applied to bodies consisting of one principle only; as the chemists take sulphur, salt, &c. to be.

The schoolmen define a *mixt body* to be a whole, resulting from several ingredients, altered or new-modified, by the mixture. On which principle the several ingredients do not actually exist in the *mixt*; but they are all changed, so as to conspire to a new body, of a different form from the form of any of the ingredients. But the modern philosophers rarely conceive the term in so much strictness.

The business of chemistry, we say, is to resolve *mixt bodies* into their principles, or component parts.

The school-philosophers distinguish *mixt bodies* into perfect and imperfect.

MIXT, *perfect*, are the class of organized and animated bodies, where the elements, or ingredients of which they are composed, are changed, or transformed, by a perfect mixture. Such are plants, beasts, and men.

MIXT, *imperfect*, are unorganized and inanimate bodies, the forms whereof remain still the same as of the ingredients that constitute them. Such are meteors, minerals, metals, &c.

MIXT, in *Chemistry*. See AGGREGATE.

MIXT, or *mixed action*, in *Law*. See ACTION.

MIXT *angle, cloth, fable*. See ANGLE, CLOTH, and FABLE.

MIXT *figure*, in *Geometry*, is that which consists partly of right lines, and partly of curve lines.

MIXT *force, history, mathematics*. See FORCE, HISTORY, and MATHEMATICS.

MIXT or *mixed larceny*. See LARCENY.

MIXT *mode*. See MODE.

MIXT *number*, in *Arithmetic*, that which is partly an integer, and partly a fraction; as $4\frac{1}{4}$.

MIXT *obligation*. See OBLIGATION.

MIXT *ratio*, or *proportion*, is when the sum of the antecedent and consequent is compared with the difference between the antecedent and consequent—as if $3 : 4 :: 12 : 16$

$a : b :: c : d$

then $7 : 1 \ldots :: 28 : 4$

$a + b : a - b :: c + d : c - d$.

MIXT *salts, stairs, service*. See SALTS, STAIRS, and SERVICE.

MIXT *tythes*, are those of cheese, milk, &c. and of the young of beasts. See TITHE.

MIXTILINEAR *angle*. See ANGLE.

MIXTION, MIXTIO, or MISTIO, the act of *mixing*; or the union and coalition of divers corpuscles into one body. The Peripatetics, who hold an alteration essential to *mixtion*, define it the union of several altered ingredients, or miscibles.

Mixtion makes a considerable operation in the chemical and Galenical pharmacy; where divers powders, species, and other simples, are said to be *mixed*, *misceri*, though without any communication, or transition of the virtues of one into those of another. See COMBINATION and COMPOSITION.

MIXTURE, MIXTURA, or MISTURA, in a philosophical sense, is an assemblage, or union, of several bodies of different properties, in the same mass.

To determine the ratio of the ingredients of a *mixture*, is that celebrated problem proposed by Hiero, king of Syracuse, to Archimedes, on occasion of a crown of gold, wherein the workman had fraudulently mixed silver; the solution whereof was matter of so much transport to that divine mechanic. See HIERO's *Crown*.

MIXTURE, in *Matters of Drapery*, denotes the union or blending of several wools of different colours, not yet spun. Hence a *mixture*, or mixed stuff, is that whose woof and warp are of wools of different colours, dyed and mixed before they were spun. See CLOTH.

MIXTURE, in *Pharmacy*, differs from a JULEP in this respect, that it receives into its composition not only salts, extracts, and other substances dissoluble in water, but also earths, powders, and such substances as cannot be dissolved.

The principal *mixtures* are the following:

Astringent mixture is made by mixing simple cinnamon-water and common water, of each three ounces; spirituous cinnamon-water, an ounce and a half; and half an ounce of japonic confection. A spoonful or two of this *mixture* may be taken every four hours, in recent dysenteries, after the necessary evacuations, interposing every second or third day a dose of rhubarb.

Diuretic mixture is prepared by mixing five ounces of mint-water, six drams of vinegar of squills, half an ounce of sweet spirit of nitre, and an ounce and a half of syrup of ginger. Two spoonfuls of this *mixture* may be taken twice or thrice a day, in obstructions of the urinary passages.

Laxative absorbent mixture is formed by rubbing one dram of magnesia alba, in a mortar, with ten or twelve grains of the best Turkey rhubarb, and adding three ounces of common water, and simple cinnamon-water and syrup of sugar, of each one ounce. In the diseases of children, arising from acidities, a table-spoonful of this *mixture* may be repeated three times a-day: when it is intended to purge, the dose may be increased; or, for very young children, diminished.

Saline mixture is made by dissolving a dram of the salt of tartar in four ounces of boiling water, and, when cold, dropping into it spirit of vitriol, till the effervescence ceases; and then adding of pepper-mint-water, two ounces, and of simple syrup, one ounce. This *mixture* may occasionally supply the place of the *saline* JULEP.

Simple mixture, the name of a form of medicine used in the prescriptions of some modern physicians. It is made by mixing ten ounces of the spiritus theriacalis camphoratus of Bates, six ounces of spirit of tartar, and two ounces of spirit of vitriol; these are to be set in a glass, hermetically sealed, for three weeks, that they may be perfectly mixed; the dose is a dram or thereabouts. Its virtues are, that it resists putrefaction, promotes sweat, and is of great service in malignant fevers.

Squill mixture is made by mixing of ſimple cinnamon-water, five ounces; vinegar of ſquills, one ounce; ſyrup of marſh-mallows, an ounce and a half. This *mixture*, by promoting expectoration, and the ſecretion of urine, proves ſerviceable in aſthmatic and dropſical caſes. A table ſpoonful of it may be taken frequently. Buchan.

MIZEN. See MIZEN.

MIZNEPHETH, in the *Jewiſh Antiquities*, a kind of mitre worn by the high-prieſt. See CIDARIS.

MIZQUITL, in *Botany*, a name uſed by ſome authors for that ſpecies of the acacia, or Egyptian thorn, whoſe unripe fruit affords the inſpiſſated juice, which is the true ſuccus acaciæ of the ſhops, and whoſe gum naturally flowing from the trunk and branches is the true gum arabic.

MNEME-CEPHALICUM *balſamum*, the name of a famous compound balſam, ſaid to have been purchaſed from a certain Engliſh phyſician by Charles duke of Burgundy, at the price of ten thouſand florins. Some who have been very lavith in its praiſes have affirmed, that it has a power of preſerving in the mind the remembrance of all things that are paſt; but this ſeems ſtretching the praiſe of it a little too far. It is prepared in the following manner: take of the juices of the leaves of baum, and baſil-juices, of the flowers of tamariſk, lilies, primroſes, roſemary, lavender, borrage, and broom, of each two ounces; of lilies of the valley, roſes, and violets, each one ounce; of cubebs, cardamoms, grains of paradiſe, and yellow ſaunders, carpobalſamum, florentine iris, ſaffron, ſavory, piony flowers, and thyme, of each half an ounce; of liquid ſtorax, ſtorax calamita, opopanax, bdellium, galbanum, gum-ivy, and labdannm, of each ſix drams; roots of long birth-wort and piony, and oil of turpentine, ſpikenard, coſtus, bays, maſtich, ben, and ſpike, of each five drams. The dry ingredients are to be beaten to powder, then mixed with the reſt, and a ſufficient quantity of water being added, the whole is to be diſtilled by an alembic, and the oil carefully ſeparated from the water. The method of uſing it is this: the firſt two months the paſſages of the ears and noſtrils are to be anointed with the ſignels of a pea of it every day; then for two months longer, the ſame is to be repeated every third day; after this it is to be uſed once a week, then once a fortnight, till a year is expired; and after this it is to be uſed once in two months for the ſucceeding years. This is the account of Sennertus. Senner. Pract. lib. i. cap. 5.

MNEMONIC *tables*. Among the artifices to aſſiſt the memory, this is one of great uſe.

Mnemonic tables exhibit in a regular manner, what is to be remembered of the ſame ſubject. And although the ſciences ought to be taught in a ſcientifical manner, as much as poſſible, and that every thing ſhould be ſo placed as to be intelligible and demonſtrable from what has preceded it; yet tables ought not to be rejected, as they are helps to retain the doctrines of which the mind has had ſufficient evidence. In ſuch tables the properties of things are to be expreſſed concicely; illuſtrations and demonſtrations ſhould be left out, as the propoſition ought to have been made ſufficiently clear and certain, before it is regiſtered in the table. Hence the contents of ſuch tables ought only to be the definitions, and the propoſitions relative to the ſubject. If a ſubject require a long table, this may be ſubdivided into ſmaller; by making firſt a table of the moſt general heads, and referring from each of theſe heads to a ſeparate tables by this means the order and connexion of the whole will be preſerved. Such tables would produce a local and *artificial* MEMORY, of great uſe to the retention and recollection of things. They would greatly facilitate a diſtinct view of the properties of their ſubjects, and facilitate recapitulation. Beſides, as the expreſſions uſed in ſuch tables ought to be very conciſe, ſo as juſt to be ſufficient to excite the idea of the object to be remembered, ſoon after that idea has been acquired; after ſome time a certain obſcurity will be found in peruſing the tables, which will give us timely warning that our ideas begin to fade, and that they ought to be renewed. And this may be done without much trouble, if not too long delayed.

MNEVIS, in *Mythology*, the name of a ſacred bull worſhipped by the Egyptians, at Heliopolis. This *Mnevis* was, according to Bryant, a compound of *Men-nevas*, the lunar god Nevas, the ſame as Noas, or Noah. The name relates to the ſame perſon who, in Crete, was called Minos; and the ſame alſo who was repreſented under the emblem of the Men-taur, or Mino-taurus. Ant. Myth. vol. ii. p. 416, &c.

MNEMOSYNE, in *Mythology*, the goddeſs of memory; which, according to Diodorus, was the daughter of Cœlum and Terra, and the ſiſter of Saturn and Rhea. Jupiter, according to the poets, fell in love with *Mnemoſyne*, and ſhe became the mother of the nine Muſes.

MNIUM, in *Natural Hiſtory*, the name of a genus of moſſes of the *cryptogamia* claſs of plants; the characters of which are theſe: it has heads of two different kinds, the one ſort naked and duſty, having no calyptra or other covering; the others are regular capſules, like thoſe of the hypnum and bryum, containing a fine powder, and covered with a calyptra or hood. This diverſity in the fructification diſtinguiſhes the *mnia* from all the other moſſes; but theſe diverſly conſtructed heads are in ſome ſpecies found on the ſame plants; in others, on different ones of the ſame ſpecies, as the male and female flowers are in hemp, mercury, and many other of the larger plants. The ſtalks which ſupport the membranaceous heads are long, and naked; thoſe which ſupport the naked heads, are in ſome naked, in others covered with leaves; but they are in all ſhorter than the others. See *Tab. of Moſſes*, N° 7.

It is the general opinion, that the fine powder, incloſed in the capſules of the hypnum and bryum, is of the nature of the farina fœcundans of the flowers of plants, and ſerves to impregnate the buds or young ſhoots in the axe of the leaves, which are the female part of the fructification in this claſs of plants; and in this ſenſe the membranaceous heads of the *mnia* contain a like farina, which impregnates the globules in theſe naked heads, and qualifies them for acting as ſeeds or young plants; but all this is rather hypotheſis and conjecture than obſervation; though Dillenius does ſuppoſe he has ſeen the germination from the globules of the duſty heads in one ſpecies of the *mnium*. Haller ſays, that theſe duſty heads are only ſo many congeries of young plants when viewed with good glaſſes, and that therefore the *mnium* is not properly a genus of plants, but ſhould be referred to the bryums, to which it belongs. All this, however, is yet but lightly founded, and the more natural opinion ſeems to be that of ſuppoſing the powder in the capſules of all the moſſes a true ſeed, not a farina. See MOSS.

There are properly two orders of the *mnium*. Thoſe of the firſt order are erect; thoſe of the latter procumbent, or creeping. Of the firſt order there are four known ſpecies: of the creeping or procumbent *mnium*, there are only three known ſpecies. Linnæus enumerates twenty-three different ſpecies.

MOAR-*burn*, in *Huſbandry*, a term uſed to expreſs a peculiar diſtemperature of corn, generally comprehended under the common term of a blight. In this caſe the earth ſinks away from the roots of the corn, and leaves the plant ſtanding in great part above ground with naked roots: theſe being too weak to ſupport the ſtalks, the plants fall and the ears become light. This is a diſtemperature peculiar to corn growing on light and looſe lands.

The remedy is this: turn a ſhallow furrow againſt the rows, when they are ſtrong enough to bear it, and the mold is fine and dry, the motion of the ſtalks with the wind will draw in this looſe powder, and it will ſpread itſelf equally among all the plants of the row, though it be triple or quadruple. It is eaſy to ſee that this remedy is only practicable in the method of the horſehoeing huſbandry; for in the common way of ſowing, there is no means of relief in this caſe: and, in general, the horſehoeing huſbandry prevents the falling of the wheat, the ſtalks never drooping ſo abſolutely in the drilled wheat as they do in that ſown in the common way.

MOAT, in *Fortification*, a deep trench dug round a town or fortreſs to be defended, on the outſide of the wall, or rampart. See *Tab. II. Fortif. fig. 21. bt. b b b*, &c.

The depth and breadth of a *moat* often depend on the nature of the ſoil; according as it is marſhy, rocky, or the like. The brink of the *moat* next the rampart in any fortification is called the *ſcarp*, and the oppoſite one the *counterſcarp*. See DITCH.

MOAT, *dry*, is that which is deſtitute of water: this ought to be deeper than one which is full of water.

MOAT, *filled*, is that whoſe ſcarp and counterſcarp are caſed with a wall of maſon's work lying aſlope.

MOAT, *flat-bottomed*, is that which hath no ſloping, its corners being ſomewhat rounded.

MOAT, *angle of the*. See ANGLE.

MOATAZALITES, MOTAZALITES, or *ſeparatiſts*, a religious ſect among the Turks, who deny all forms and qualities in the divine Being; or who diveſt God of his attributes.

There are two opinions among the Turkiſh divines concerning God. The firſt admits metaphyſical forms, or attributes; as, that God has wiſdom, by which he *is* wiſe; power, by which he is powerful; eternity, by which he is eternal, &c.

The ſecond allows God to be wiſe, powerful, eternal; but will not allow any form or quality in God, for fear of admitting a multiplicity.

Thoſe who follow this latter opinion are called *Moatazalites*: they who follow the former, *Sephalites*.

The *Mutazalites* alſo believed that the word of God was created *in ſubjecto*, as the ſchoolmen term it, and to conſiſt of letters and ſounds; copies thereof being written in books to expreſs or imitate the original; they denied abſolute predeſtination, and affirmed that man is a free agent. This ſect is ſaid to have firſt invented the ſcholaſtic divinity, and is ſubdivided into no leſs than twenty inferior ſects, which mutually brand one another with infidelity. Sale's Prelim. Diſc. p. 159, &c.

MOBILE, *movable*, any thing ſuſceptible of motion, or that is diſpoſed to be moved either by itſelf, or by ſome other prior *mobile*, or mover.

MOBILE, *primum*, in the *Ancient Aſtronomy*, was a ninth heaven, or ſphere, imagined above thoſe of the planets, and fixed ſtars.

This was ſuppoſed to be the firſt mover, and to carry all the lower ſpheres round along with it; by its rapidity communicating to them a motion whereby they revolved in twenty-four hours. But the diurnal revolution of the planets is now accounted for, without the aſſiſtance of any ſuch *primum mobile*.

MOBILE, *perpetuum*. See *Perpetual* MOTION.

MOBILES, in the *Ancient Muſic*, was an appellation given to the two intermediate chords of a tetrachord; becauſe their variations produced the different genera and ſpecies of muſic. They were called by the Greeks κινούμεναι, or κινούμενοι.

MOBILIA *bona*, in the *Civil Law*, are what in common law, &c. we call *moveables*, or *moveable goods*.

MOBILITY, in the *Schools*, &c. an aptitude or facility to be moved.

The *mobility* of mercury is owing to the ſmallneſs and ſphericity of its particles; and it is this which alſo renders its fixation ſo difficult.

The hypotheſis of the *mobility* of the earth is the moſt plauſible; and is that univerſally admitted by the later aſtronomers.

Pope Paul V. appointed commiſſioners to examine the opinion of Copernicus touching the *mobility* of the earth. The reſult of their inquiry was, a prohibition to aſſert, not that the *mobility* was poſſible, but that it was actually true; that is, they allowed the *mobility* of the earth to be held as an hypotheſis, which gives an eaſy and ſenſible ſolution of the phænomena of the heavenly motions; but forbad the *mobility* of the earth to be maintained as a theſis, or real effective thing; becauſe they conceived it contrary to ſcripture. See COPERNICAN *ſyſtem*.

MOCHLICA, a term by which ſome authors call the violent or draſtic purges.

MOCHO or MOCOA *ſtones*. See AGAT and DENDRITIS.

MOCHUS, in *Botany*, a name uſed by ſome authors for the orobus, or bitter vetch. Dodonæus, beſide others, calls it by this name.

MOCK *bird*, the name of an American bird called, by Ray, *turdus Americanus minor canorus*, and very much approaching to the cœruleous or blauvogel. It is of the ſize of the common lark; its beak is ſhort and ſtrait; its tail very long; and its whole body of a very fine deep blue. It vies with the nightingale in melody and is called by the Indians *contototlli*, which is ſaid to ſignify four hundred tongues.

MOCK *lead*, in *Mineralogy*, a name given by the Engliſh writers to a ſort of foſſil, called alſo BLENDE and GALENA. It has very much the appearance of an ore of lead, being bright and glolſy, of a bluiſh black colour, and plated; but on trial it is found to yield very little or none at all of that metal.

MOCK *nightingale*. See BLACK-*cap*.

MOCK *orange*, in *Botany*. See PHILADELPHUS.

MOCK *privet*. See *Mock* PRIVET.

MOCK, or running a *muck*, is a practice that has prevailed time immemorial in Batavia. To *run a muck*, in the original ſenſe of the word, is to get intoxicated with *opium*, and then ruſh into the ſtreet, with a drawn weapon, and kill any one that comes in the way, till the party is himſelf either killed or taken priſoner. If the officer takes one of theſe *amucks*, or *mohawks*, (as they have been called by an eaſy corruption,) alive, he has a conſiderable reward, and the unhappy wretches are always broken alive on the wheel: but ſuch is the fury of their deſperation, that three out of four are neceſſarily deſtroyed, in attempting to ſecure them.

MODAL, in *Logic*, &c. a term applied to propoſitions which include certain conditions and reſtrictions.

MODE, or MOOD, *modus*, in *Philoſophy*, a *manner* of being; or a quality or attribute of a ſubſtance, or ſubject, which we conceive as neceſſarily depending on the ſubject, and incapable of ſubſiſting without it.

Mr. Locke defines *modes* to be thoſe ideas (he ſhould have ſaid *things*) which do not imply any ſuppoſition of ſubſiſting by themſelves, but are conſidered as mere dependences, and affections of ſubſtances.

Our ideas of things may be reduced to two kinds: the one of things, which we conceive ſeparately, and by themſelves, called *ſubſtances*; and the other of things which we conceive as exiſting in others, in ſuch manner as that we cannot allow them exiſting without them, and theſe we call *modes* or *accidents*.

It is the characteriſtic, then, of a true *mode*, to have ſuch a relation to ſome ſubject, as not to be clearly and diſtinctly conceivable without conceiving the ſubject, whereof it is a *mode*, at the ſame time: when, on the other hand, the conception of the ſubject does not at all infer or require that of the *mode*.

Thus, what gives us to know, that thought is not a *mode* of extended ſubſtance, or matter, is, that extenſion, and the other properties of matter, may be divided from thought, without ceaſing to conceive thought all the while.

We always conſider things as clothed with certain *modes*, except we reflect on them in the abſtract, or general: and it is the variety of *modes*, and the relations, that occaſions the great variety of denominations of the ſame thing. They are the various *modes* of matter, e. g. that make all the diverſity of bodies, or corporeal beings, in nature.

There are various diviſions and kinds of *modes*: as, 1. *eſſential* or *accidental*. An *eſſential mode*, or ATTRIBUTE, is that which belongs to the very nature or eſſence of the ſubject wherein it is; and the ſubject can never have the ſame nature without it, as roundneſs in a bowl, ſolidity in matter, thinking in a ſpirit, &c. and this is *primary*, when it is the firſt or chief thing, that conſtitutes any being in its particular eſſence or nature, and makes it to be that which it is, and diſtinguiſhes it from all other beings; as roundneſs in a bowl; or *ſecondary*, which is any other attribute of a thing, that is not of primary conſideration, called a PROPERTY; as volubility in a bowl. An *accidental mode*, or ACCIDENT, is ſuch a *mode*, as is not neceſſary to the being of a thing; for the ſubject may be without it, and yet remain of the ſame nature, which it had before; or it is that *mode*, which may be ſeparated from its ſubject; as blackneſs or whiteneſs in a bowl, learning in a man, &c.

2. *Modes* are *abſolute* and *relative*. An *abſolute mode* is that which belongs to its ſubject, without reſpect to any other beings whatſoever. A *relative mode* is derived from the regard which one being has to others: thus, roundneſs and ſmoothneſs are the *abſolute modes* of a bowl; but greatneſs and ſmallneſs are *relative*. See RELATION.

3. *Modes* are *intrinſical* or *extrinſical*. The former are conceived to be in the ſubject or ſubſtance; as when we ſay a globe is round, &c. The latter *mode* is a manner of being which ſome ſubſtances attain by reaſon of ſomething that is external or foreign to the ſubject, and is called external denomination; as this globe lies within two yards of the wall, &c.

4. *Modes* are alſo *inherent* or *adherent*, i. e. *proper* or *improper*. *Adherent modes* ariſe from the joining of ſome accidental ſubſtance to the chief ſubject, which yet may be ſeparated from it; as when a bowl is wet, &c. *Inherent modes* have a ſort of in-being in the ſubſtance itſelf; as the bowl is ſwift or round, &c.

5. *Action* and *paſſion*, uſing the terms in a philoſophical ſenſe, are *modes* which belong to ſubſtances; as when a ſmith with a hammer ſtrikes a piece of iron, the ſmith and hammer are agents or ſubjects of action, and the iron is the patient or ſubject of paſſion.

6. *Modes* may be divided into *natural*, *civil*, *moral*, and *ſupernatural*, all which pertain to the apoſtle Paul, who was a little man, a Roman by the privilege of his birth, a man of virtue or honeſty, and an inſpired apoſtle.

7. *Modes* belong either to *body*, or to *ſpirit*, or to both. *Modes* of *body* belong only to matter, or to corporeal beings; ſuch are FIGURE, REST, MOTION, &c. Theſe are *primary*, when they belong to bodies, conſidered in themſelves, whether there were any man to take notice of them or no, as ſhape, ſize, &c. or *ſecondary*, which are ſuch ideas as we aſcribe to bodies, on account of the various impreſſions that are made on the ſenſes of men, by them, called ſecondary qualities; ſuch are all colours, ſounds, taſtes, ſmells, and all tactile qualities. See QUALITY. *Modes* of *ſpirit* belong only to minds, ſuch are KNOWLEDGE, WILL, &c. *Modes* belonging to body and ſpirit are called mixt or human *modes*, becauſe they are found in human nature, ſuch are SENSATION, IMAGINATION, PASSION, &c. in which there is a concurrence of the operation of animal and intellectual nature.

8. There are alſo *modes* of other *modes*, which, though they ſubſiſt in and by the ſubſtance, as the original ſubject of them, are properly and directly attributed to ſome *mode* of that ſubſtance; thus ſwiftneſs and ſlowneſs are *modes* of motion, which is itſelf the *mode* of a body.—Watts's Logic. p. i. c. 2. § 3 and 4.

Mr.

Mr. Locke divides *modes* into *simple*, and *mixt* or *compound*.

MODES, *simple*, are combinations of simple ideas of the same kind, or even of the same simple ideas divers times repeated: as a dozen, a score, &c. which are only the ideas of so many distinct units put together.

The modifications of any simple idea, Mr. Locke observes, are as perfectly different and distinct ideas in the mind as those the most remote and inconsistent: thus, *two* is as distinct from *three*, as blindness is from heat. With this view that author examines the *simple modes* of space; which are found to be distance, capacity, extension, figure, place, and duration.

The mind has several distinct ideas of *sliding*, *rolling*, *twisting*, *creeping*, &c. which are all but the different modifications of motion. *Swift* and *slow* are two different ideas of motion, the measures whereof are made out of the distances of time and space put together.

The like variety we have in sounds; every articulate word is a different modification of sound, as are all notes of different length put together, which make that complex idea called *time*.

The *modes* of colours might be also very various: some of which we take notice of as the different degrees, or as they are termed, *shades of the same colour*. But since we seldom make assemblages of colours without taking in figure also, as in painting, &c. those which are taken notice of, do most commonly belong to mixed *modes*; as *brown*, *rainbow*, &c. All compounded tastes and smells are also *modes* made up of the simple ideas of those senses.

As to the *modes of thinking*; when the mind turns its view inward upon itself, *thinking* is the first idea that occurs, wherein it observes a great variety of modifications; and therefore frames to itself distinct ideas.

Thus the perception annexed to any impression on the body made by an external object, is called *sensation*. Where an idea recurs without the presence of the object, it is called *remembrance*. When sought after by the mind, and brought again in view, it is called *recollection*. When held there long under attentive consideration, it is called *contemplation*. When ideas float in the mind without regard or reflection, it is called, in French, a *reverie*. When the ideas are taken notice of, and, as it were registered in the memory, it is *attention*. When the mind fixes its view on any one idea, and considers it on all sides, it is *intention* and *study*.

Of these various *modes* of thinking, the mind forms as distinct ideas, as it does of white and red, or of a square, or a circle.

MODES, *mixt*, are combinations of simple ideas of several kinds; as in *beauty*, which consists in a certain composition of colour, figure, &c. *theft*, which is the concealed change of possession of any thing, without consent of the proprietor, &c.

There are three ways whereby we get ideas of *mixt modes*. 1. By experience and observation of things themselves: thus, by seeing two men wrestle, we get the idea of wrestling. 2. By invention, or voluntarily putting together of several simple ideas in our own minds: so he that first invented printing had an idea of it first in his mind before ever it existed. 3. By explaining the names of actions we never saw, or notions we cannot see; and by enumerating all those ideas, which go to the making them up: thus, the *mixt mode* which the word *lye* stands for is made up of the simple ideas, (1.) Articulate sounds. (2.) Certain ideas in the mind of the speaker. (3.) Words, the signs of those ideas. And, (4.) those signs put together by affirmation, or negation, otherwise than the ideas they stand for are in the mind of the speaker.

Mixt modes have their unity from an act of the mind, combining those several simple ideas together, and considering them as one complex one: the mark of this union is one name given to that combination.

This gives the reason, why there are words in every language, which cannot be rendered by any one single word of another. For the fashions and customs of one nation make several combinations of ideas familiar in one, which another had never any occasion to make. Such were ὀστρακισμὸς among the Greeks, and *proscriptio* among the Romans.

This also occasions the constant change of languages; because the change of custom and opinion brings with it new combinations of ideas, which, to avoid long descriptions, have new names annexed to them, and so they become new species of *mixt modes*.

Of all our simple ideas, those which have had most *mixt modes* made out of them, are thinking, and motion (which comprehend in them all action), and power, from whence these actions are conceived to flow.

Of this kind are the *modes* of actions distinguished by their causes, means, objects, ends, instruments, time, place, and other circumstances; as also of the powers fitted for those actions. Thus *boldness* is the power to do or speak what we intend, without fear or disorder; and this power of doing any thing, when it had been acquired by frequent doing the same thing, is that idea we call *habit*; and when forward and ready, upon every occasion, to break into action, we call it *disposition*: thus *testiness* is a disposition or aptness to be angry. Power being the source of all action, the substances, wherein those powers are, when they exert this power, are called *causes*: and the substances thereupon produced, or the simple ideas introduced into any subject, are called *effects*. The efficacy whereby the new substance or idea is produced, is called in the subject exerting that power, *action*; and, in the subject wherein any simple idea is changed, or produced, *passion*: which efficacy, in intellectual agents, we can conceive to be nothing else but *modes* of thinking and willing: in corporeal agents, nothing else but modifications of motion.

MODE, *division of a*. See DIVISION.

MODE, in *Grammar*. See MOOD.

MODE, in *Logic*. See MOOD.

MODE is also used, in logic, for the modification of a proposition; or that which renders it *modal* and *conditional*.

MODE, *indirect*. See INDIRECT.

MODE, or MOOD, in *Music*, a particular manner of beginning, continuing, and ending a song, whereby we are engaged to make use of certain notes, or chords, preferable to, or oftener than others.

MODE is defined by some authors, the particular manner of constituting the octave, or the melodious constitution of the octave, as it consists of seven essential or natural notes, besides the key, or fundamental.

A *mode*, then, is not any single note or sound; but the particular order of the conciunous degree of an octave: the fundamental note whereof may, in another sense, be called the *key*, as it signifies that principal note which regulates the rest.

The proper difference between a *mode* and a KEY, consists in this, that an octave, with all its natural and conciunous degrees, is called a *mode* with respect to the constitution, or the manner and way of dividing it; and with respect to the place of it in the scale of music, that is, the degree or pitch of tune, it is called a *key*: that is, an octave of sounds may be raised in the same order and kind of degrees which makes the same *mode*, and yet be begun higher or lower; that is, be taken at different degrees with respect to the whole, which makes different keys: and from the same definition it follows, that the same key may be found with different *modes*; that is, the extremes of two octaves may be in the same degree of tune, and the division of them different.

Now it may be farther observed, that of the natural notes of every *mode*, or octave, three go under the name of the essential notes in a peculiar manner, viz. the fundamental, the third, and fifth; their octaves being reckoned the same, and marked with the same letters in the scale: the rest are particularly called *dependents*. Again, the fundamental is also called the *final*; the fifth, the *dominante*; and the third, as being between the other two, the *mediante*.

The doctrine of the ancients, with regard to *modes*, which they sometimes also call *tones*, is somewhat obscure; there being an unaccountable difference among their authors as to the definitions, divisions, and names of their *modes*. They agree, indeed, that a *mode* is a certain system or constitution of sounds; and that an octave, with all its intermediate sounds, is such a constitution: but the specific differences of tones, or *modes*, some place in the manner of division, or order of their conciunous parts; and others merely in the different tension of the whole; i. e. as the whole series of notes are acuter or graver, or as they stand higher or lower in the scale of music.

Boethius is very obscure on this head, and defines a *mode* to be, as it were, an entire body of modulation, consisting of a conjunction of consonances; as the diapason.

Ptolemy makes the *modes* the same with the species of the diapason; but at the same time he speaks of their being at some distance from each other. Some contended for thirteen, some for fifteen *modes*, which they place at a semitone's distance from each other; but it is plain, these understood the differences to be only in their place, or distances from each other; and that there is one certain harmonious species of octave applied to them all; viz. that order which proceeds from the proslambanomenos of the systema immutatum, or the A of the modern system. Ptolemy argues, that if this be all, they may be infinite, though they must be limited for use and practice. But, indeed, much the greater part define them by the species of the DIAPASON; so that as there are in nature three different kinds of diatessaron, and four

different

different kinds of diapente; and the diapaſon is compoſed of theſe two ſyſtems: there are in nature ſeven ſpecies of diapaſon, and therefore only ſeven *modes*; but as to their uſe, we are left entirely in the dark.

If the *modes* be nothing but the ſeven ſpecies of octaves, the uſe of them can only be, that the proſlambanomenos of any *mode* being made the principal note of a ſong, there may be different ſpecies of melody anſwering to thoſe different conſtitutions. But then we are not to conceive, that the proſlambanomenos, or fundamental of any *mode*, is fixed to any particular chord of the ſyſtem, v. g. the Phrygian to g; ſo that we muſt always begin there, when we would have a piece of melody of that ſpecies. When we ſay, in general, that ſuch a *mode* begins in g, it is no more than to ſignify the ſpecies of octave as they appear in a certain fixed ſyſtem: but we may begin in any chord of the ſyſtem, and make it the proſlambanomenos of any *mode*, by adding new chords, or by altering the tuning of the old. If this were the true nature and uſe of the tones, muſt of theſe *modes* muſt have been imperfect, and incapable of good melody, as wanting ſome of thoſe which we reckon the eſſential and natural notes of a true *mode*. Again, if the eſſential difference of the *modes* conſiſt only in the gravity or acuteneſs of the whole octave, then we may ſuppoſe one ſpecies or concinnous diviſion of the octave, which, being applied to all the chords of the ſyſtem, makes them true fundamentals for a certain ſeries of ſucceſſive notes, by changing, as above, the tone of certain chords in ſome caſes, or by adding new chords to the ſyſtem. But that muſt have been a ſimple kind of melody, produced by admitting only one concinnous ſeries, and that too wanting ſome uſeful and neceſſary chords.

Sir Francis Haſkins Eyles Styles, in an elaborate eſſay on the *modes* of the ancients, Phil. Tranſ. vol. li. 695, &c. has undertaken to prove, that the two doctrines on this ſubject, which he diſtinguiſhes by the epithets of harmonic and muſical, and which have been advanced by different writers, are in reality the ſame. According to one of theſe, viz. the harmonic, the difference between one *mode* and another conſiſted in the tenſion or pitch of the ſyſtem; and, according to the other, or muſical, this difference conſiſted in the manner of dividing an octave, or in the different ſpecies of the diapaſon: but both theſe definitions of a muſical *mode* perfectly coincide. This author obſerves, that, according to the harmonic doctrine, the number of the *modes* had been augmented to fifteen; but Ptolemy, who appears to have favoured the muſical, reduces them to ſeven: of theſe ſeven, according to the direction furniſhed by Bacchius, p. 12. ed. Meibom. it appears, that the Mixolydian was the moſt acute; the Lydian graver by a ſemitone; the Phrygian graver than the Lydian by a tone; the Dorian graver than the Phrygian by a tone; the Hypolydian graver than the Dorian by a ſemitone; the Hypophrygian graver than the Hypolydian by a tone; and the Hypodorian graver than the Hypophrygian by a tone. Now as the Guidonian ſcale, in uſe among the moderns, anſwers to the ſyſtem of the ancients, in its natural ſituation, which was in the Dorian *mode*, and our A la mi re conſequently, anſwers to the pitch of the Dorian meſe: we have a plain direction for finding the abſolute pitch of the meſes, for all the ſeven in our modern notes, and they will be found to ſtand thus:

Mixolydian meſe in	*d*
Lydian in	*c ſharp.*
Phrygian in	*b*
Dorian in	*a*
Hypolydian in	*g ſharp*
Hypophrygian in	*f ſharp*
Hypodorian in	*e*

But to underſtand this doctrine as delivered by the ancients, it will be neceſſary alſo to examine, how the meſes of the ſeven *modes* were ſtationed upon the lyre. The lyre, after its laſt enlargements, conſiſted of fifteen ſtrings, which took in the compaſs of a diſ-diapaſon, or double octave. Theſe ſtrings were called by the ſame names as the fifteen ſounds of the ſyſtem; and, when tuned for the Dorian *mode*, correſponded exactly with them. In this *mode*, the meſe of the ſyſtem was placed in the meſe of the lyre; but in every one of the reſt, it was applied to a different ſtring, and every ſound of the ſyſtem tranſpoſed accordingly. Hence ariſe the diſtinction between a ſound in power, and a ſound in poſition; for when the ſyſtem was tranſpoſed from the Dorian to any other *mode*, e. g. to the Phrygian, the meſe of the lyre, though ſtill meſe in poſition, acquired in this caſe the power of the lichanos meſon; and the parameſe of the lyre, though ſtill parameſe in poſition, acquired the power of the meſe. In theſe tranſpoſitions, one or more of the ſtrings always required new tunings, to preſerve the relations of the ſyſtem; but, notwithſtanding this alteration of their pitch, they retained their old names, when ſpoken of, in reſpect to their poſitions only; for the name implied not any particular pitch of the ſtring, but only its place upon the lyre, in the numerical order, reckoning the proſlambanomenos for the firſt. The places of the meſe for theſe ſeven *modes* upon the lyre, are ſettled by Ptolemy as follow:

			ſtring.
Mixolydian		Parameſe diezeugmenon	11
Lydian		Triteſe diezeugmenon	10
Phrygian		Parameſe	9
Dorian	Meſe in	Meſe	8
Hypolydian		Lichanos Meſon	7
Hypophrygian		Parhypate Meſon	6
Hypodorian		Hypate Meſon	5

On the other hand, the muſical doctrine taught, that the difference between one *mode* and another conſiſted in the manner of dividing an octave, or in the different ſpecies of diapaſon. Theſe were, as we have already obſerved, ſeven in number; and had the denominations of Mixolydian, Lydian, Phrygian, Dorian, Hypolydian, Hypophrygian, and Hypodorian. See DIAPASON.

Theſe ſpecies, as they ſtand in the ſyſtem, are with reſpect to acuteneſs and gravity, in the inverted order of the ſeven *modes* as ſettled by the harmonic doctrine. According to the Guidonian ſcale, and preſerving the natural notes, they will ſtand in the manner repreſented under DIAPASON.

The order of the intervals of which each ſpecies is compoſed, proceeding in each from grave to acute, will be as follows:

Mixolydian. Semitone, tone, tone, ſemitone, tone, tone, tone.

Lydian. Tone, tone, ſemitone, tone, tone, tone, ſemitone.

Phrygian. Tone, ſemitone, tone, tone, tone, ſemitone, tone.

Dorian. Semitone, tone, tone, tone, ſemitone, tone, tone.

Hypolydian. Tone, tone, tone, ſemitone, tone, tone, ſemitone.

Hypophrygian. Tone, tone, ſemitone, tone, tone, ſemitone, tone.

Hypodorian. Tone, ſemitone, tone, tone, ſemitone, tone, tone.

The ancients had another method of explaining the ſpecies of diapaſon, by the poſition of the diazeuctic tone, or interval from meſe to parameſe. In the mixolydian ſpecies, the diazeuctic tone was the firſt interval, reckoning from acute to grave; in the Lydian, it was the ſecond; in the Phrygian, the third; in the Dorian, the fourth; in the Hypolydian, the fifth; in the Hypophrygian, the ſixth; and in the Hypodorian, the laſt.

In order to reconcile the two doctrines already illuſtrated, it is obſerved, by ſir Francis Styles, that the harmonic doctrine ſhews the pitch of the ſyſtem for each *mode*; and the muſical directs in what part of the ſyſtem to take the ſpecies of diapaſon; therefore, by combining theſe two directions, we obtain the following canon for obtaining any *mode* required: "firſt pitch the ſyſtem for the "*mode*, as directed by the harmonic doctrine; then ſelect "from it the diapaſon, directed by the muſical, and "we have the characteric ſpecies of the *mode* in its true "pitch." The annexed diagram of the ſeven ſpecies ſhews at what pitch of the Guidonian ſcale each ſound of the diapaſon is brought out by the canon for each of the ſeven *modes*. The reſult of the canon, ſeen in the conſtruction of the diagram, is, in all reſpects, conformable to the principles of both doctrines; e. g. in the Dorian, the meſe is placed in A la mi re, and the reſt of the ſounds exhibited, in that diapaſon, are placed at the proper diſtances, for preſerving the order of the ſyſtem, as required by the harmonic doctrine. It is alſo ſeen, that the diapaſon ſelected lies between the hypate meſon and nete diezeugmenon; that the ſemitones are the firſt interval in the grave, and the third in the acute; and that the diazeuctic tone is in the fourth interval, reckoning from the acute, &c. all which circumſtances were required by the muſical doctrine for this *mode*; and all the circumſtances required by each doctrine will be found to obtain in the reſt of the *modes*.

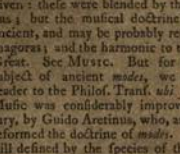
The same author has explained at large the eight harmonic *modes* rejected by Ptolemy, and his reasons for excluding them. He has also traced the origin of the two doctrines, of which a summary has been already given: these were blended by the followers of Aristoxenus; but the musical doctrine appears to be the most ancient, and may be probably referred to the age of Pythagoras; and the harmonic to the age of Alexander the Great. See MUSIC. But for a farther view of this subject of ancient *modes*, we must refer the curious reader to the Philos. Trans. *ubi supra*.

Music was considerably improved in the eleventh century, by Guido Aretinus, who, among other innovations, reformed the doctrine of *modes*. It is true, they were still defined by the species of the octave, in Ptolemy's manner; and their number was fixed to seven; but afterwards taking occasion to consider the harmonical and arithmetical divisions of the octave, whereby it resolves into a fourth above a fifth, or a fifth above a fourth, they hence constituted twelve *modes*, making of each octave two different *modes*, according to this different division: but because there are two of them that cannot be divided both ways, there are but twelve *modes*. Of these, such as were divided harmonically, that is, with the fifths lowest (which were fix), were called *authentic*; and the other fix, which had the fifths highest, were called *plagal modes*. See the scheme annexed.



To these *modes* they gave the names of the ancient Greek tones, as Dorian, Phrygian, and Lydian; but the several authors differ in the application and order of these names: so that we are still in great measure at a loss to know what they meant by those distinctions, and what their real use was. The best account we can give was this: they considered that an octave, which wants a fourth or fifth, is imperfect; these being the concords next to octave, the song ought to touch those chords most frequently and remarkably; and because their concord is different, which makes the melody different, they

eſtabliſhed by this two *modes* in every natural octave that had a true fourth and fifth: then, if the ſong was carried as far as this octave above, it was called a *perfect mode*; if leſs, as to the fourth or fifth, it was called *imperfect*; if it moved both above and below, it was called a *mixt mode*. Thus it is that ſome authors ſpeak about theſe *modes*. Others, conſidering how indiſpenſable a chord the fifth is in every *mode*, took for the final, or key-note, in the arithmetically divided octaves, not the loweſt chord of that octave, but that very fourth. The only difference then in this method between the authentic and plagal *modes* is, that the authentic goes above its final to the octave; the other aſcends a fifth, and deſcends a fourth; which will indeed be attended with different effects; but the *mode* is eſſentially the ſame, having the ſame final to which all the notes refer.

We are now to conſider wherein the *modes* of one ſpecies, as authentic or plagal, differ among themſelves: this muſt either be by their ſtanding higher or lower in the ſcale, i. e. by the different tenſion of the whole octave, or rather by the different ſubdiviſions of the octave into its concinnous degrees: there can be no other. We are to conſider then, whether theſe differences are ſufficient to produce ſuch very different effects as are aſcribed to the ſeveral *modes*; for inſtance, that the one produces mirth, another ſadneſs, that a third is proper for religion, a fourth for love, &c. That theſe effects are owing merely to the conſtitution of the octave, ſeaces any body will affirm. The differences in the conſtitution will, indeed, have ſome influence; but it will be ſo little, as by that the various combinations of other cauſes, one of theſe *modes* may be uſed to different purpoſes. The greateſt difference is that of thoſe octaves which have the third *b*, or third *♯*, making what on other occaſions we call the *ſharp* and *flat key*.

However, if the *modes* depend upon the ſpecies of octaves, how can they be more than ſeven? And as to the diſtinction between authentic and plagal, we have already obſerved, that it is imaginary with reſpect to any eſſential difference conſtituted thereby in the kind of the melody: for though the carrying the ſong above or below the final, may have different effects, yet this is to be aſcribed to other cauſes beſides the conſtitution of the octaves. It is particularly obſervable, that thoſe authors, who give us examples in actual compoſition of their twelve *modes*, frequently take in the artificial notes *♯* and *b*, to perfect the melody of their key; and by this means depart from the conſtitution of the octave, as it ſtands fixed in the natural ſyſtem. There is nothing certain or conſiſtent, therefore, in their way of ſpeaking; but the *modes* are all really reducible to two, viz. the ſharp and flat; the other differences reſpecting only the place of the ſcale where the fundamental is taken.

The ancient *modes*, beſides their general diviſion into authentic and plagal, had alſo their reſpective names from the ſeveral Greek provinces where they are ſuppoſed to have been invented. Originally indeed there were but three, viz. Doric, Lydian, and Phrygian; which were particularly called *tones*, becauſe at a tone's diſtance from one another. The reſt were added afterwards, aand were ſome of them named from the relations they bore to the former, particularly the *Hypo-doric*, as being below the Doric. See the preceding part of this article.

The *Doric* MODE was a mixture of gravity and mirth, invented by Thamyras of Thrace.

The *Phrygian* MODE was adapted to the kindling of rage; and was invented by Marſyas the Phrygian.

The *Lydian* MODE was proper for amorous or funeral ſongs; and was invented, according to Pliny, by Amphion.

The *Myxolydian* was invented by Sappho. The *Aolic*, *Ionic*, and *Hypo-doric* by Philoxenus. And the *Hypobaſtian* by Polymneſtes. See DORIC, &c.

Beſides theſe *modes of tune*, old authors have alſo introduced *modes of time*, or meaſures of notes. Theſe at firſt were diſtinguiſhed into greater and leſs, and each of theſe again into perfect and imperfect. But afterwards they reduced all into four *modes*, which included the whole buſineſs of time. As theſe *modes* are now diſuſed, they are hardly worth the reciting.

The common *mode* now in uſe is much more ſimple and natural than any of theſe: the proportion, which in theſe's varied, being in our's fixed; viz. 2: 1. A large equal to two longs; a long to two breves; a breve to two ſemibreves, &c. proceeding in the ſame proportion to the laſt or loweſt notes. And if on ſome occaſions the proportion of 3: 1 betwixt two ſucceſſive notes is required, it is eaſily expreſſed by annexing a point (.).

The ancients had likewiſe their *mode melicpoiae*, of which Ariſtides names theſe; *dithyrambic*, *nomic*, and *tragic*: which were called *modes*, from their expreſſing the ſeveral motions and affections of the mind.

MODEL, an original or pattern propoſed for any one to copy or imitate.

St. Paul's church is ſaid to be built after the *model* of St. Peter's at Rome.

MODEL is particularly uſed in building, for an artificial pattern, made of wood, ſtone, plaiſter, or other matter, with all its parts and proportions; in order for the better conducting and executing ſome great work, and to give an idea of the effect it will have in large.

In all great buildings it is much the ſureſt way to make a *model* in relievo; and not to truſt to a bare deſign, or draught. There are alſo *models* for the building of ſhips, &c. and for extraordinary ſtair-caſes, &c.

MODEL, in *Painting* and *Sculpture*, is any thing propoſed to be imitated. And

Hence, in the academies, they give the term *model* to a naked man, diſpoſed in ſeveral poſtures, to give an opportunity to the ſcholars to deſign him in various views and attitudes.

The ſculptors have little *models* of clay or wax to aſſiſt them in their deſigns of others that are larger, in marble, &c. and to judge of the attitude and correctneſs of a figure.

Statuaries likewiſe give the name *model* to certain figures of clay or wax, which are but juſt faſhioned, to ſerve by way of guide for the making of larger, whether of marble or other matter.

MODERATA *miſericordia*, in *Law*, a writ that lies for him who is amerced in a court baron or other court not of record, for any tranſgreſſion beyond the quality or quantity of the offence. It is directed to the lord of the court, or his bailiff, commanding them to take a *moderate amercement* of the party. This writ is founded upon *Magna Charta*.

If a man be amerced in a court-baron on preſentment by the jury, where he did not any treſpaſs, he ſhall not have this writ, unleſs the amercement be exceſſive and outrageous; and if the ſteward of the court, of his own head, will amerce any tenant or other perſon without cauſe, the party ought not to ſue for this writ of *moderata miſericordia* if he be diſtrained for that amercement; but he ſhall have action of treſpaſs. New. Nat. Br. 167.

When the amercement which is ſet on a perſon is aſſeered by his peers, this writ of *moderata miſericordia* doth not lie; for then it is according to the ſtatute 10 Edw. II.

MODERATION, in *Ethics*, is a virtue conſiſting in the proper government of our appetites, paſſions, and purſuits, with reſpect to honours, riches, and pleaſures; and in this ſenſe it is ſynonymous with TEMPERANCE: it is alſo often uſed to denote *candour*.

MODERATOR, in the *Schools*, the perſon who preſides at a diſpute, or in a public aſſembly.

Such a doctor was the *moderator*, that is, the preſident, at ſuch a diſputation, in ſuch an aſſembly, &c.

MODERATOR-*ring*, in *Anatomy*, is uſed by Valſalva for that ring which the muſcles of the eye make round the optic nerve, at the bottom of the orbit. He alleiges, that the exterior fibres of theſe muſcles which riſe from the nerve, muſt ſhorten it when they contract, and when the interior fibres act they muſt compreſs it; ſo that theſe different fibres of the muſcles affect the nervous fluid here very differently.

Valſalva alſo deſcribes ſuch another ring made round the motory nerves of the eye; but acknowledges, that it is neither ſo remarkable nor diſtinct as the former. Med. Eſſ. Edimb. Abr. vol. ii. p. 410.

MODERN, ſomething *new*, or of our *time*. In oppoſition to what is antique, or *ancient*.

Modern authors, according to Naude, are all thoſe who have written ſince Boethius: the *modern* philoſophy commences with Galileo: and the *modern* aſtronomy with Copernicus.

MODERN *medals* are reckoned all thoſe that have been ſtruck within theſe three hundred years. See MEDAL.

MODERN, in *Architecture*, is improperly applied to the preſent, or Italian manner of building; as being according to the rules of the antique. Nor is the term leſs abuſed when attributed to architecture purely Gothic.

Modern architecture, in propriety, is only applicable to that which partakes partly of the antique, retaining ſomewhat of its delicacy and ſolidity; and partly of the Gothic, whence it borrows members and ornaments, without proportion or judgment.

MODERN *muſic*, *muſica moderna*, may be divided into two parts: firſt, *antiqua-moderna*, which is generally a ſerious ſort of muſic, conſiſting of many parts; and which has been in uſe from Guido's time, to the beginning of the laſt century. Secondly, the *modern* which has been uſed in this and the laſt century; it is very different from the *antiqua-moderna*, being briſker, lighter, gayer, and more ſprightly.

MODESTY, in *Ethics*, is ſometimes uſed to denote HU-

MILITY.

MILITY; and sometimes to express chastity or purity of sentiment and manners.

MODIFICATION, in *Philosophy*, that which *modifies* a thing; that is, gives it this or that manner of being.

Quantity and quality are accidents which *modify* all bodies.

According to Spinoza's system, all the beings that compose the universe are only so many different *modifications* of one and the same substance. And the different arrangement and situation of their parts, make all the difference between them.

MODIFICATIVE, something that *modifies*, or gives a thing a certain manner of being.

Father Buffier establishes a new part of speech, which he calls *modificative*. Nouns and verbs, he observes, are susceptible of divers circumstances or *modifications*: in the phrase, *wise acts*, we have a noun and verb, without any *modification*; but in that, *wise without discretion acts rashly*, the noun and verb are each attended with a *modification* or circumstance.

The last kind of words, which serve to *modify* nouns and verbs, since they have no general name in the common grammars, he chooses to call *modificatives*: which include what grammarians commonly call *adverbs*, *conjunction*, and *prepositions*.

MODILLIONS, from the Italian *modiglione*, a little *measure*, in *Architecture*, ornaments in the cornice of the Ionic, Corinthian, and Composite columns. See *Tab. Archit. fig.* 20.

The *modillions* are little inverted consoles, or brackets, in form of an S, under the soffit of the cornice, seeming to support the projecture of the larmier: though in reality they are no more than ornaments.

The *modillion* is sometimes also called *mutule*; though custom has introduced a little difference between the idea of a *modillion*, and a mutule; the mutule being peculiar to the Doric order, and the *modillion* to the higher orders.

The *modillions* ought always to be placed over the middle of the column. They are particularly affected in the Corinthian order, where they are usually enriched with sculpture. Their proportions must be so adjusted, as to produce a regularity in the parts of the soffit.

The *intermodillions*, i. e. the distances between them, depend on the intercolumniations, which require the *modillions* to be made of a certain length and breadth, in order to render the intervals perfect squares, which are always found to have better effect than parallelograms. To this it must be added, that in adjusting the *modillions*, care should be taken, that they have such a proportion, as that when the orders are placed over one another, there be the same number in the upper order as in the lower, and that they fall perpendicularly over each other.

Modillions are also used under the cornices of pediments; though Vitruvius observes, that they were not allowed of in his time; in regard *modillions* were intended to represent the ends of rafters, which could not be supposed to be found in a pediment.

Some will have the *modillions* of a pediment to represent purlins; and those at the eaves to represent rafters. Daviler rather takes them for a kind of inverted consoles or corbels.

In the Corinthian order it is usual to have a leaf which takes up the whole breadth, and almost the whole length of the *modillions*; but Le Clerc is of opinion, that they would be more graceful if this leaf were less, both in length and breadth. The leaf ought likewise to be of the same kind with those which make the ornament of the capital.

MODIOLI, in *Natural History*, a name given by some authors to the trochitæ or single joints of the rays of the petrified magellanic star-fish, which, when connected in numbers together, form that fossil called ENTROCHUS. Others have also used this word *modiolus* to express the compound body, or entrochus itself. Though the general form of the trochitæ be thin and flat, yet they are sometimes found considerably thick; and though the entrochi or compound *modioli* are usually so many cylinders of equal diameter in all parts, yet there are sometimes found such as are thick in the middle, and thence gradually taper to each end; some also are composed of joints, each of this form; these differ very greatly from the common kind, and instead of consisting of a number of little wheels, are made up of a series of little barrels, joined, as it were, end to end.

MODIOLUS, a surgeon's instrument, the same with ANABAPTISTON, and TREPANUM.

MODIUS, in *Antiquity*, a kind of dry MEASURE in use among the Romans for several sorts of grain.

The *modius* contained thirty-two heminæ, or sixteen sextaries; or $\frac{1}{3}$ of the amphora; amounting to an English peck.

MODIRA *kaniram*, in *Botany*, a name given by some authors to the tree whose wood is the *lignum colubrinum*, or snake-wood of the shops.

MODO *& forma*, in *Law*, a phrase used in processes and pleadings, whereby the defendant absolutely denies the thing charged on him by the plaintiff, *modo & forma declaratis*, in the manner and form set forth.

The civilians in the like sense say, *negat allegata, probat allegantur, esse vera*.

MODULATION, in *Music*, is the art of keeping in, and, on occasion, changing, the mode or key; and returning to it again; without offence to the ear.

Under this term is comprehended the regular progression of the several parts through the sounds that are in the harmony of any particular key, as well as the proceeding naturally and regularly from one key to another.

The rules of *modulation* in the first sense belong to harmony and melody. We shall here only add a word with regard to the rules of *modulation* in the latter sense.

As every piece must have a principal key; and since the variety, so necessary in music to please and entertain, forbids the being confined to one key; and that therefore it is not only allowable, but necessary, to *modulate* into, and make cadences on several other keys, having a relation and connection with the principal key: it must be considered what it is that constitutes a connexion between the harmony of one key, and that of another, that it may be hence determined into what keys the harmony may be conducted with propriety.

As to the manner in which the *modulation* from one key to another is to be performed, so that the transition may be easy and natural; it is not easy to fix any precise rules: for though it is chiefly performed by the help of the seventh *g* of the key, into which the harmony is to be changed, whether it be flat or sharp; yet the manner of doing it is so various and extensive, that no rules can easily circumscribe it. A general notion of it may be conceived under the following terms.

The seventh *g* in either flat or sharp key is the third *g* to the fifth *f* of the key, by which the cadence in the key is chiefly performed; and by being only a semitone under the key, is thereby the most proper note to lead into it, which it does in the most natural manner imaginable: insomuch that the seventh *g* is never heard in any of the parts, but the ear expects the key should succeed it: for whether it be used as a third, or as a fifth, it always affects us with so imperfect a sensation, that we naturally expect something more perfect to follow, which cannot be more easily and smoothly accomplished than by the small interval of a semitone, to pass into the perfect harmony of the key. Hence it is, that the transition into one key is best effected by introducing its seventh *g*, which is naturally leads to it.

MODULE, in *Architecture*, a certain measure, taken at pleasure, for regulating the proportions of columns, and the symmetry or distribution of the whole building.

Architects usually choose the diameter or semidiameter of the bottom of the column for their *module*; and this they subdivide into parts, or minutes.

Vignola divides his *module*, which is a semidiameter, into twelve parts, for the Tuscan and Doric; and into eighteen, for the other orders.

The *module* of Palladio, Scamozzi, M. Cambray, Desgodetz, Le Clerc, &c. which is also the semidiameter, is divided into thirty parts, or minutes, in all the orders.

Some divide the whole height of the column into twenty parts for the Doric, twenty-two and a half for the Ionic, twenty-five for the Roman, &c. and one of these parts they make a *module*, to regulate the rest of the building by.

There are two ways of determining the measures or proportions of buildings; the first by a fixed standard measure, which is usually the diameter of the lower part of the column, called a *module*, subdivided into sixty parts, called *minutes*. In the second there are no minutes, but any certain and stated division of the *module*; but it is divided occasionally into as many parts as are judged necessary. Thus, the height of the Attic base, which is half the *module*, is divided either into three, to have the height of the plinth; or into four, for that of the greater torus; or into six, for that of the lesser.

Both these manners have been practised by the ancient as well as the modern architects; but the second, which was that chiefly used among the ancients, is in the opinion of Perrault preferable.

As Vitruvius, in the Doric order, has lessened his *module*, which in the other orders is the diameter of the lower part of the column, and has reduced that great *module* to a mean one, which is a semidiameter; M. Perrault reduces the *module* to a third part for the same reason, viz. to determine the several measures without a fraction. For in the Doric order, beside that the height of the base, as in the other orders, is determined by one of

those

theſe mean *modules*; the ſame *module* gives likewiſe the heights of the capital, architrave, triglyphs, and metopes. But our little *module*, taken from the third of the diameter of the lower part of the column, has uſes much more extenſive; for, by this, the heights of podeſtals, of columns, and entablatures, in all the orders, are determined without a fraction.

As then the great *module* or diameter of the column, has ſixty minutes; and the mean *module*, or half the diameter, thirty minutes; our little *module* has twenty. See COLUMN.

MODUS *decimandi* is when a parcel of land, a ſum of money, or a yearly penſion, belongs to the parſon, either by compoſition or cuſtom, time out of mind, in ſatisfaction for tithes in kind.

This is ſometimes a pecuniary compenſation, as two pence an acre for the tithe of land; ſometimes it is a compenſation in work and labour, as that the parſon ſhall have only the twelfth cock of hay, and not the tenth, in conſideration of the owner's making it for him: ſometimes in lieu of a large quantity of crude or imperfect tithe, the parſon ſhall have a leſs quantity, when arrived to greater maturity, as a couple of fowls inſtead of tithe eggs, &c. In ſhort, any means whereby the general law of tithing is altered, and a new method of taking tithes is introduced, is called a *modus decimandi*, or ſpecial manner of tithing. In order to make a good and ſufficient *modus*, the following rules muſt be obſerved:

1. It muſt be certain and invariable. 2. The thing, given in lieu of tithes, muſt be beneficial to the parſon, and not for the emolument of third perſons only. 3. It muſt be ſomething different from the thing compounded for. 4. One cannot be diſcharged from payment of one ſpecies of tithe, by paying a *modus* for another. 5. The recompence muſt be in its own nature as durable as the tithes diſcharged by it; i. e. an inheritance certain. 6. The *modus* muſt not be too large, which in law is called a rank *modus*. In theſe caſes of preſcriptive or cuſtomary *moduſes*, the law ſuppoſes an original real compoſition to have been regularly made, which being loſt by length of time, the immemorial uſage is admitted as evidence to ſhew that it did once exiſt, and that from thence ſuch uſage was derived. Now time of memory hath been long aſcertained by the law, to commence from the reign of Richard I. and any cuſtom may be deſtroyed by evidence of its non-exiſtence in any part of the long period from his days to the preſent. Blackſt. Com. b. ii. p. 30.

MOEDA. See MOIDORE.

MOEHRINGIA, *mountain chick-weed*, in *Botany*, the name of a genus of plants of the *octandria digynia* claſs, deſcribed by Linnæus; the characters of which are theſe: the perianthium ſtands expanded, and is compoſed of four leaves, of a lanceolated figure; the flower is compoſed of four petals of an oval figure not indented at the ends, and ſmaller than the ſegments of the cup; the ſtamina are eight capillary filaments; the antheræ are ſimple; the germen of the piſtil is globoſe; the ſtyles are two, they are erect and of the length of the ſtamina; the ſtigmata are ſimple; the fruit is a globoſe capſule, compoſed of four valves, but having only one cell in which are ſeveral ſeeds, convex on one ſide and angular on the other. There is only one ſpecies.

MOERDA. See MURDER.

MOGORIN, in *Botany*, a name given by the Portugueſe to an Indian or Chineſe flower, growing on a ſmall ſhrub. It is of a wonderful white colour, and not unlike the *yin-ſing*, only that it abounds more with leaves, and ſmells much ſweeter; one ſingle flower filling a whole houſe with its odoriferous effluvia. On this account the Chineſe put a high value upon it, and carefully defend the ſhrub it grows on from the inclemency of the winter, by covering it with vaſes provided on purpoſe.

MOHAIR, in *Commerce*, the hair of a kind of GOAT, frequent about Angora, in Turkey; the inhabitants of which city are all employed in the manufacture of camblets made of this hair.

Some give the name *mohair* to the camblets or ſtuffs made of this hair: of theſe there are two kinds; the one ſmooth and plain; the other watered like tabbies: the difference between the two only conſiſts in this, that the latter is calendered, the other not. There are alſo *mohairs* both plain and watered, whoſe woof is of wool, cotton, or thread.

MOHAIR, *unwatered*, pays $6\frac{72}{100}d.$ per yard on importation and draw-back, on exportation, $6\frac{72}{100}d.$ The watered ſort pays on importation $11\frac{44}{100}d.$ per yard, and draws back, on exportation $10\frac{72}{100}d.$ And that made of half hair, half ſilk, pays on importation $2s.\ 10\frac{16}{100}d.$ per yard, and draws back, on exportation, $2s.\ 7\frac{72}{100}d.$

MOHAIR-*ſtuff*, in *Natural Hiſtory*. See MOIRE.

MOHAWKS *corn*, in *Botany*, a name given by the Indians to a peculiar ſort of the MAIZE, or Indian corn. It is moſt frequent in the more northerly parts of America. The general time of ſowing the maize in Virginia and other places, is in the end of April; but this *mohawk* kind need not be ſown before June, and yet will come well to maturity before the winter. The ſtalks of this kind are ſhorter than thoſe of the common ſort. The ears alſo are ſhorter, and grow nearer the ground, and the corn is generally of various colours. Phil. Tranſ. N° 142.

MOHAWKS. See MOCK.

MOIDORE, MOIDORE, or MOEDA, a gold coin, ſtruck and current in Portugal.

The *moidore* and its diviſions, are reckoned by the ree, and being numbered on the coin, the value of each piece is thus readily known. Thus that marked

four millrees	4000	is worth	£. 1: 7: 0	Engliſh money.
	2000		0: 13: 6	
	1000		0: 6: 9	
	500		0: 3: 4½	

See REE.

The *moidore* is properly the Portugueſe *piſtole*.

There are alſo *doppio-moedas*, or double *moidores*, or piſtoles, and demi-piſtoles.

MOIETY, MEDIETAS, the *half* of any thing.

MOILON, is a name given by the French to a kind of ſtone, that forms the upper cruſt and lies round the free-ſtone in moſt quarries. It is an excellent ſubſtance for forming the body of fluxes or ſoft enamel.

MOINEAU, in *Fortification*, is a flat baſtion raiſed before a curtin when it is too long, and the baſtions of the angles too remote to be able to defend one another.

Sometimes the *moineau* is joined to the curtin, and ſometimes it is divided from it by a moat. Here muſqueteers are placed, to fire each way.

MOIRE, in *Conchyliology*, the mohair ſhell, a name given by the French virtuoſi to a peculiar ſpecies of VOLUTA, which ſeems of a cloſely and finely reticulated texture, and reſembles on the ſurface a piece of mohair, or a very cloſe ſilk-worm's web.

MOISTURE. See HUMIDITY.

The *moiſture* of the air has conſiderable effects on the human body. For the quantity and quality of the food, and the proportion of the meat to the drink, being given, the weight of a human body is leſs, and conſequently its diſcharges greater in dry weather than in wet weather; which may be thus accounted for: the *moiſture* of the air moiſtens the fibres of the ſkin, and leſſens perſpiration, by leſſening their vibratory motion. When perſpiration is thus leſſened by the *moiſture* of the air, urine, indeed, is by degrees increaſed, but not equally. See Dr. Bryan Robinſon's Diſſ. on the Food and Diſcharges of the Human Bodies, p. 68, ſeq.

Hence we learn, that to keep a body of the ſame weight in wet weather as in dry, either the quantity of food muſt be leſſened, or the proportion of the meat to the drink increaſed; and both theſe may be done by leſſening the drink, without making any change in the meat.

The inſtrument uſed for determining the degree of *moiſture* in the air, is called an HYGROMETER. Since the printing of that article, Mr. Coventry, of Southwark, has furniſhed the editor with an account of his new hygrometer, the conſtruction of which is as follows: take two ſheets of fine tiſſue paper, ſuch as is uſed by hatters and watch-makers, and ſometimes called Jawn-paper, each ſheet of which generally weighs about twenty-ſeven grains. Let the moiſture be thoroughly evaporated by the fire, without ſcorching the paper; till after repeated trials it is brought to its drieſt ſtate: in this ſtate cut each ſheet till it weighs exactly twenty-five grains. Theſe ſheets, thus prepared, ſhould be kept in a box or drawer with a quantity of the ſame paper deſigned for uſe; and they will always ſerve for determining the proper weight of any quantity of paper for other hygrometers. This paper hung in any place, and kept free from duſt, and weighed with a nice pair of ſcales, will ſerve to exhibit the *moiſture* of the air, by its increaſe of weight above fifty grains. But to avoid the trouble of weighing, Mr. Coventry prepared an hygrometer of it in in the following manner. A, *Tab.* III. *Pneumatics*, *fig.* 49. repreſents a pillar ſupporting the beam B B, to one end of which are ſuſpended fifty grains of paper D, cut round, and threaded on a ſilk ſtring, with a ſmall glaſs bead between the ſheets, for the freer admiſſion of the air: at the other end of the beam is a braſs weight E, to counterbalance the weight of the paper and its appendages. At the bottom there is an ivory ſcale F F, of twelve prime diviſions, anſwering to twelve grains of *moiſture*: each prime diviſion is ſubdivided into ten parts, making in the whole one hundred and twenty diviſions: on the index C is a ſliding weight G, which, with the weight E on the beam, ſerves to adjuſt the inſtrument; ſo that twelve grains ſhall make the index juſt traverſe the ſcale of the twelve

twelve divisions. If the air was so dry as to leave no *moisture* in the paper, the index would then point to 0: if it contained six grains of *moisture*, the index would point to sixty; if twelve grains were in the paper, it would point to the moist extreme one hundred and twenty: but the air has never yet been observed so moist, as to make the index point to the moist extreme, nor so dry as to allow its reaching to the driest extreme, even in the hottest part of summer, by nearly twenty divisions: whence it is inferred that there is in the air a greater quantity of *moisture* in hot weather than is generally imagined. H is an adjusting screw for fixing the stand upright by means of the point of a plumbet that hangs behind. This hygrometer, adjusted, may be made to correspond with another, ascertained to the same weight at any distance: by which we might determine the exact difference of the state of the air, with respect to *moisture*, in inland, and places near the sea-side. The advantages of this hygrometer are the following: as it is made of the thinnest substance that can be procured, it is the soonest affected with dryness or *moisture*, and exhibits immediately the first change of the weather: it is not acted upon by heat and cold, or any other cause, as most other instruments of this kind are: it has one datum from which to reckon; viz. the dry extreme, whence all other degrees of *moisture* may be nicely estimated. All hygrometers of this sort will act nearly alike, as thermometers or barometers; and may be reduced to a regular standard. Mr. Coventry found by this hygrometer, that in clear frosty weather, the air contains a very considerable degree of *moisture*: for on Jan. 27, 1776, in the morning, being a very hard frost, the thermometer in the house 24°, and in the open air 17°, the hygrometer stood at ten grains, i. e. at the division 100: and on the next morning, when a thaw came on, it stood at 96; which shews that there is as much *moisture* in the air during the frost, as when we perceive it dissolved in a thaw. He adds, that it is pleasing to observe the constant motion of this hygrometer: for even in constant settled weather, it is always in motion, from moist towards dry, from about eight in the morning till about four in the afternoon; and from dry to moist, from about 4 P. M. to about 8 A. M. In hot gloomy weather, the hygrometer is mostly found to advance with speed towards moist, and shews that the air at such times retains a great quantity of *moisture*: and this always forebodes heavy showers. For curious experiments some of these hygrometers are made to traverse the whole scale of divisions for every grain of *moisture* that is imbibed by the papers.

MOISTURE *radical*. See RADICAL.

MOLA, in *Medicine*. See MOLE.

MOLA, in *Ichthyology*. See SUN-*fish*.

MOLA, in *Anatomy*, a bone of the knee, called also *patella*, *rotula*, &c. See *Tab. Anat. (Osteol.) fig.* 23, *n.* 21, 22.

MOLAGO *codi*, in *Botany*, a name by which some authors have called the plant which produces the common black pepper.

MOLANGA, in *Botany*, a name given by some authors to the plant which produces the common black pepper.

MOLAR *glands*, or *glandulæ molares*, so called by Heister, who first described them, are two glands situated between the masseter and buccinator, which send out small ducts perforating the buccinator, and opening into the cavity of the mouth, almost over against the *dentes molares*.

MOLARES, in *Anatomy*, the *grinders*; an epithet given to the large teeth; as serving, like mill-stones, to grind the food. See *Tab. Anat. (Osteol.) fig.* 7. *lit. f.*

The number of *molares* is not always the same. Some persons have twenty; and others only sixteen, viz. four or five on each side of either jaw. They are very large, hard, and strong; being fastened into their alveoli or sockets by several roots.

The *molares* have been, according to the difference in their size, distinguished into small grinders, large grinders, and *dentes sapientiæ*, or the teeth of wisdom, so called, because they seldom appear till people are arrived at years of discretion.

The bodies of the *molares* in general are very thick, short, and irregularly cylindrical, or rather with four sides, a little rounded, and terminated by a broad end, more or less filled with obtuse points, cut, in some measure, like so many diamonds. The name of *crown* is also frequently given to the bodies of these teeth, from some sort of resemblance they are supposed to have to it. In the two small *molares*, the crown is less than in the others, and often not so large as the bodies of the canini: they have usually but two points. In the two large *molares*, the crown has a much greater extent, and the points are three, four, or five in number. The fifth grinder, or *dens sapientiæ*, has usually a crown much like the two former, but commonly more rounded, and with fewer points. The roots of the *molares* are long, and more or less flat; in some single, in others two, three, or four, and sometimes, but rarely, five in number; sometimes all these roots are distinct, sometimes they are wholly united, and sometimes they are united only in part; they are generally strait, and at a greater distance from one another at their extremities than at the crown of the tooth. The roots of the small grinders appear often single, without being so in reality; for in examining them narrowly, they are found to have two roots united, or foldered together; and sometimes all the distinction that appears, is in their having two separate points. The great *molares* have commonly several roots, the first three, and the second four; or sometimes, the first four, and the second five; but these numbers are variable. The roots are sometimes all perfectly distinct, and sometimes they are partly distinct, and partly united in the same tooth in different degrees; and in some subjects, one or more of their points are bent outward, inward, or in other directions; and it is not always that more roots are met with in the upper teeth than in the lower. The fifth grinder has often but one root, and that is sometimes very short, and sometimes remarkably long. It is common to meet with this tooth in grown persons, almost wholly hid in its socket, and it has, in these cases, but a very small opening for it to appear at. In all the *molares*, near the collar, the roots, be they ever so many, meet and unite into one body. Winslow's Anatomy, p. 49.

MOLARES, in the *Natural History of the Ancients*, the name for the compound mineral bodies we now call PYRITES, and MARCASITES.

MOLASSES. See MOLOSSES.

MOLD. See MOULD.

MOLDAVICA, in *Botany*. See DRAGON's *head*.

MOLE, *talpa*, in the Linnæan system of *Zoology*, makes a distinct *genus* of animals, of the order of *feræ*, and class of *mammalia*: the characters of which are, that they have six upper fore-teeth, and eight lower; and the first of the laniarii is larger, and four smaller. Linnæus reckons two species, viz. the European, which has a tail, and five toes on its feet, and the Asiatic or Siberian, which has no tail, and three toes on the fore-feet.

The *mole*, though a very common animal, is very little observed by the generality of the world. Its fur is very short, soft and thick; its nose is like that of a hog; and its teeth like those of the *mus araneus*, being single and eminent on the sides of the upper jaw, and those farther within the mouth armed with many points; it has scarce any neck, its head seeming to be set between its shoulders; its legs are very short, its claws very sharp, and its toes five in number on each foot; the inner part or sole of the fore-feet is very broad, and much resembles the palm of the human hand; its claws on these are more robust and strong than in any other animal of its size; the whole feet and toes are not placed downward but sideways, for the sake of the creature's continual employment in digging, it being properly a subterranean animal; its tail is short, and hairy.

It has been supposed by many, that the *mole* had no eyes; and others have affirmed, that it had eyes, but that they were covered with a membrane; but neither of these assertions are true; the eyes are small, and have apertures in the skin, through which they may easily be discerned by a curious observer; and are very black, about the size of a millet-seed, and fastened to a nerve.

The reason they have not been observed by the common people, is, that they are hid by the fur; but, on blowing that away, they always shew themselves; it has no ears. Its skin is extremely firm and tough, so that it requires a sharp knife to pierce it.

This seems the care of nature to defend the creature from the cold; and the fineness of the fur, that is the smallness of every hair, seems proportioned to the small pores they had to grow out of.

The hair is usually black, sometimes spotted with white; and sometimes quite white. This animal has an exquisite sense of smelling, which directs it to its food, viz. worms, insects, and roots. It breeds in the spring, and brings forth four or five young at a time. It makes its nest of moss, a little beneath the surface of the ground, and screams much when taken. Palma christi and white hellebore, made into a paste, and laid in their holes, destroy them. There are no *moles* in Ireland. See *Tab.* III. *Quadrupeds*, N° 34. A yellowish kind of *mole* inhabits North America. The Siberian *mole* is of a beautiful green and gold colour, variable with the light. Ray and Pennant.

MOLE, MOLA, or MOLA *carnea*, in *Medicine*, a misshapen mass of hard flesh, sometimes generated in the wombs of women, instead of a fœtus; called also a *false conception*. The Latins give it the name *mola*, which literally signifies *mill-stone*, from its resemblance to it in form.

The *mole* is the chaos of an embryo; and would have grown to an infant, had not the process of conception been disturbed. Though it be without regular bones, viscera, &c. yet the lineaments frequently are not so far effaced, but that there are some remains of a child; sometimes a hand, and sometimes a foot, have been seen; and commonly the secundines.

It is rare that more than one *mole* is excluded at a time; though Scanertus observes there are instances of two, three, or even more. He adds, that though they usually come alone, yet they have been known to come with a fœtus, sometimes before it, and sometimes after it.

The *mole* is distinguished from an *embryo*, in that it has no placenta whereby to receive its nourishment from the mother. Instead of that it grows immediately to the womb; and is nourished there.

It has a kind of vegetative life, and continues growing in bulk till the time of exclusion. Sometimes it has been borne in the womb for two or three years.

This production is supposed to arise from some defect or indisposition of the ovum, or egg; or, perhaps, from the male's seed wanting force to penetrate it sufficiently in order to open or expand the parts: or, the effect may be accounted for, by supposing an ovum to drop into the womb, without being impregnated by the seed of the male: in all which cases, the egg continuing to grow, and yet wanting something necessary to organize and form it into an embryo, becomes a shapeless lump.

Authors are divided whether or no women ever bring forth *moles* without any intercourse with men? Some say there are *moles* which derive their origin from the menstruous blood detained, coagulated, and hardened; through which the blood and spirits have made themselves passages, &c.

The *mole*, while in the womb, may be distinguished from a true conception, by its tremulous palpitating motion; by its rolling from side to side; and by the belly's swelling equally every way. The breasts swell as in case of a just embryo; but the humour generated therein is not true milk, but a crude matter, formed of the suppressed menses.

To bring the *mola* out of the womb, bleeding and violent purging are used, and at last strong emmenagogues. If these fail, recourse is to be had to manual operation.

A *mole* is sometimes produced alone in the uterus, sometimes at the same time with a regular fœtus. There are many origins to be assigned to these concretions, but the most usual seems to be the leaving behind a part of the secundines after abortion. In young people these are less dangerous, and seldom remain in the womb more than a year, but in older persons they sometimes remain many years, and at length often occasion the death of the person. When they are produced in the womb at the same time with a regular fœtus, they usually deprive it of part of its nutriment, and occasion false pains, and many irregular complaints, during the time of gestation; but these usually are attended with fewer accidents at the time of delivery than when the same substances are produced alone in the womb. The German writers of wonders give accounts of these concretions being living animals, armed with claws and beaks, or wide mouths, and destroying the fœtus when they are in the womb at the same time with one; but these are idle reports, and are to be looked upon in the same light with the histories of sooterkins. Junk. Conf. Med. p. 721.

The signs of a *mole* in the uterus are very dubious, and during the first months of gestation, it is scarce possible to distinguish it from a genuine fœtus; but after this, if the symptoms of pregnancy go on, and there is no motion perceived at a time when the fœtus ought to stir, it is shrewdly to be suspected that this is the case; and this becomes the more evident, if after this time there come on irregular and uncertain discharges of blood from the uterus, at different times; in this case there is also usually so great a flaccidity in the ligaments of the uterus, that it does not retain its place in the body; but when the person turns in bed, is plainly felt falling like a dead weight from one side of the abdomen to the other. It is also observed, that in these cases, though the belly swells as much as when there is a genuine fœtus, yet it is not so regularly rounded before, but is flatter at the middle, and more turgid toward the sides, so that the burden seems carried on one or the other side, or partly in both, while the middle remains empty. There is always in this case also a sensation of a weight on the lower part of the abdomen, greater by much than in the case of a real a child there. At the regular time of delivery, the case becomes much plainer than before; for then either no pains at all come on, or those which come are slight, and inconsiderable, very irregular in their periods and returns, and by no means sufficient for the exclusion of a fœtus. When the *mole* happens at the same time with the fœtus, it is seldom to be discovered till the time of delivery, or if it be found out sooner, there can be nothing done till both that and the fœtus are excluded; after this the womb is to be very carefully cleansed, as in abortions. At other times, when the case is obvious, that there is a *mole* without any fœtus, the common forcing medicines are to be given for several days every month, about the time of the periodic returns of the menses; and if those do not bring it away, recourse is to be had to the hand of the midwife.

We find a very singular instance in Kerkring, of a *mole*, in which a child was inclosed. The whole was declared a false conception, and might have been sacrificed as such, had not some person present observed something stir within it, and, on the opening it, taken out the living child.

MOLE, MOLES, a massive work formed of large stones laid in the sea by means of cosser-dams, extended either in a right line, or an arch of a circle, before a port; which it serves to close; to defend the vessels in it from the impetuosity of the waves, and to prevent the passage of ships without leave.

Thus we say the *mole* of the harbour of Messina, &c.

MOLE is sometimes also used to signify the harbour itself.

MOLE, MOLES, among the Romans, was also used for a kind of mausoleum, built in manner of a round tower on a square base, insulate, encompassed with columns, and covered with a dome.

The *mole* of the emperor Adrian, now the castle of St. Angelo, was the greatest, and most stately, of all the *moles*. It was crowned with a brazen pine-apple, wherein was a golden urn containing the ashes of the emperor.

MOLE *cricket*, *gryllotalpa*, in *Zoology*. See *Mole* CRICKET.

MOLE-*hills*. These little hillocks of earth are a very great prejudice to the pasture-lands, not only in wasting so much of the land as they cover, but in hindering the scythe in mowing. In the west of England they use a peculiar instrument for the breaking up of these; it is a flat board, very thick, and of about eight inches in diameter, into which there is fastened a perpendicular handle of three or four feet long. It has four broad and sharp iron teeth at the front, which readily cut through the hill, and spread the earth it consists of; and behind there is a large knob, proper for breaking the clods with, if there are any. Some use a spade, or other common instrument, in the place of this, but not so well. There is, however, a much better instrument even than this, for destroying these hills, where they are in very great numbers. This is a kind of horse-machine; it has a sharp iron about three feet over, and with a strong back. It is about four or five inches broad, and has two long handles for a horse to be harnessed to, and a cross bar of iron to strengthen it at the bottom of the handles, reaching from the one handle to the other. The middle of this cross bar is furnished with one, two, or more, sharp pieces of iron, like small plough-shares, to cut the *mole-hills* into two, three, or more parts. The iron behind is of a semicircular figure. A single horse is harnessed to this machine, and a boy must be employed to drive it, and a man to hold and guide it; the sharp irons or shares are the first things that meet the hill, they run through it, break its texture, and cut it into several parts, and the circular iron following immediately behind them, cuts up the whole by the roots, and leaves the land level. This instrument will destroy as many *mole-hills* in one day as a common labourer can in eight, and would be of very great advantage to the kingdom, if brought into general use. Mortimer's Husbandry, p. 331.

It is to be observed, that this leaving a naked space in the place of every hill, it will be necessary to go over the land, and sow them with hay seed, otherwise these spots will want the produce of grass the first years. The farmers in some parts of England are not willing to destroy the *mole-hills*, but let them stand from year to year, supposing that they get some ground by them; but the advantage by this means is so little that it does not balance the unsightliness and damage to the mowing.

MOLECULE, MOLECULA, in *Physics*, a little mass or portion of any body.

The air, by respiration, insinuating itself into the veins and arteries, endeavours by its elastic power to divide and break the *molecules* of the blood, which on their part resist such division.

MOLES *carnea*, in *Anatomy*, a name given by Vesalius, and others, to a muscle, called by Winslow, Albinus, and others, the COMPLEXUS. Spigelius calls it the *carnea moles trigemino adjuncta*.

MOLES *carnea labia formans*, in *Anatomy*, a name given by Fallopius to the muscle called by Albinus *orbicularis oris*, and by Cowper CONSTRICTOR *labiorum*.

MOLESTANDO. See NON *molestando*.

MOLINE', in *Heraldry*. A *croſs* MOLINE' is that which turns round both ways at all its extremities, though not ſo wide or ſharp as that ſaid to be *anchored*.
In Upton, the points are all cut off, which makes it very different from the croſs anchored.

MOLINISTS, in *Eccleſiaſtical Hiſtory*, a ſect in the Romiſh church, who follow the doctrine and ſentiments of the Jeſuit Molina, relating to ſufficient and efficacious grace. Lewis Molina, after whoſe name this ſect was called, was a Spaniſh Jeſuit, and profeſſor of divinity in the univerſity of Ebora, in Portugal; in the year 1588, he publiſhed a book, to ſhew that the operations of divine grace were entirely conſiſtent with the freedom of human will; and he introduced a new kind of hypotheſis to remove the difficulties attending the doctrines of predeſtination and liberty, and to reconcile the jarring opinions of Auguſtinians, Thomiſts, Semi-Pelagians, and other contentious divines. Molina affirmed, that the decree of predeſtination to eternal glory was founded upon a previous knowledge and conſideration of the merits of the elect; that the grace, from whoſe operation theſe merits are derived, is not efficacious by its own intrinſic power only, but alſo by the conſent of our own will, and becauſe it is adminiſtered in thoſe circumſtances, in which the Deity, by that branch of his knowledge, which is called *ſcientia media*, foreſees that it will be efficacious. The kind of preſcience, denominated in the ſchools *ſcientia media*, is that foreknowledge of future contingents, that ariſes from an acquaintance with the nature and faculties of rational beings, o the circumſtances in which they ſhall be placed, of the objects that ſhall be preſented to them, and of the influence which theſe circumſtances and objects muſt have on their actions.
The great antagoniſts of the *Moliniſts* are the JANSENISTS.

MOLINOSISTS, a ſect among the Romaniſts, who adhere to the doctrine of Molinos. Theſe are the ſame with what are otherwiſe called QUIETISTS.

MOLLE, in *Botany*. See *Indian* MASTIC.

MOLLE, in *Ichthyography*, the name of a ſmall ſpecies of whiting, common in the Mediterranean, and in the markets of Rome, Venice, &c. and called by authors the *aſellus omnium minimus*, and the *merlangus*. It is the ſmalleſt of all the aſellus kind, ſeldom exceeding four inches in length; it has a beard like the cod, hanging from the angle of its lower jaw; and has on each ſide nine ſpots on its noſe and gills; the back is of a pale brown, the belly white, and it has extremely ſmall and ſoft ſcales. The fleſh is very delicate.

MOLLE, in the *Ancient Muſic*, a name given to a ſpecies of the DIATONIC; and alſo to a ſpecies of the CHROMATIC.
The Greeks call it μαλακὸν, and uſed the term in oppoſition to *intenſum*, συντονον. As the latter was formed by increaſing the tenſion of the chord, and thereby making it approach nearer to the higheſt extreme of the tetrachord; ſo the *molle* was formed by remiſſion or relaxation. Hence the diviſion of the diatonic into *molle*, μαλακὸν, and *intenſum*, συντονον. Ariſtoxenus, p. 50, 51. edit. Meibom. See GENUS.

MOLLET. See MULLET.

MOLLIS *portio*. See PORTIO.

MOLLUGO, *African chick-weed*, in *Botany*, a genus of the *triandria trigynia* claſs. Its characters are theſe: the empalement of the flower is compoſed of five oblong ſmall leaves, coloured on their inſides and permanent; the flower has five oval petals ſhorter than the empalement; and three briſtly ſtamina, which ſtand near the ſtyle, terminated by ſingle ſummits; it has an oval germen, having three furrows, ſupporting three very ſhort ſtyles: the germen becomes an oval capſule with three cells, filled with ſmall kidney-ſhaped ſeeds. There are ſeveral ſpecies, few of which are admitted into gardens. Miller reckons two, and Linnæus five ſpecies.
This plant is ſaid to have an aperitive virtue.

MOLLUSCA, in the Linnæan ſyſtem, is the denomination of the ſecond *genus* of *vermes* or worms. Theſe are ſimple naked animals, not included in a ſhell, but furniſhed with limbs, and comprehend eighteen ſubordinate genera, and one hundred and ten ſpecies.

MOLMAN, in our *Old Writers*, a man ſubject to do ſervice. It is applied to the ſervants in a monaſtery.

MOLMUTIN, or MOLMUTIAN *laws*, the laws of Dunwallo Molmutius XVI. king of the Britons, who is ſaid to have begun his reign four hundred and forty years before the incarnation.
He was the firſt who publiſhed any laws in this land; and they continued famous therein till the time of William the Conqueror.

MOLOCH, an affected term uſed by ſome chemical writers, to expreſs a leaden pot, through which mercury is made to paſs in the fire.

MOLOCH, in *Antiquity*, the name of the Phœnician god. See DÆMON.

MOLOCHITES, in *Natural Hiſtory*. See MALACHITES.

MOLOPS, a word uſed by ſome medical writers, to expreſs the purple ſpots which appear upon the ſkin in malignant fevers.

MOLOSSES, MOLASSES, or MELASSES, that groſs, yet fluid matter remaining of ſugar, after refining, and which no boiling will bring to a conſiſtence more ſolid than that of ſyrup; hence alſo called *ſyrup of* SUGAR.
Properly, *moloſſes* are only the the ſediment of one kind of ſugar called *clyppre*, or brown ſugar, which is the refuſe of other ſugars not to be whitened, or reduced into loaves.
Moloſſes are much uſed in Holland among poor people, for the preparation of tobacco, and alſo inſtead of ſugar. There is a kind of BRANDY or ſpirit made of *moloſſes*; but by ſome held exceedingly unwholeſome.

MOLOSSES, *artificial*. There has been found a method of making *moloſſes* from apples, without the addition of ſugar. The apple that ſucceeds beſt in this operation is a ſummer-ſweeting of a middle ſize, pleaſant to the taſte, and ſo full of juice, that ſeven buſhels will yield a barrel of cyder.
The manner of making it is this: the apples are to be ground and preſſed, then the juice is to be boiled in a large copper, till three quarters of it be evaporated: this will be done with a moderate fire in about ſix hours, with the quantity of juice above mentioned; by this time it will be of the conſiſtence and taſte as well as of the colour of *moloſſes*.
This new *moloſſes* ſerves to all the purpoſes of the common kind, and is of great uſe in preſerving cyder. Two quarts of it, put into a barrel of racked cyder, will preſerve it, and give it an agreeable colour.
The invention of this kind of *moloſſes* was owing to Mr. Chandler, of Woodſtock, in New England, who living at a diſtance from the ſea, and where the common *moloſſes* was very dear and ſcarce, provided this for the ſupply of his own family, and ſoon made the practice general among the people of the neighbourhood. It is to be obſerved, that this ſort of apple, the ſweeting, is of great uſe in making cyder, one of the very beſt kinds we know being made of it. The people in New England alſo feed their hogs with the fallings of their orchards of theſe apples; and the conſequence of this is, that their pork is the fineſt in the world. Phil. Tranſ. N° 174, p. 230.

MOLOSSES *ſpirit*; a very clean and pure ſpirit, much uſed in England, and made from *moloſſes* or common treacle diſſolved in water, and fermented in the ſame manner as malt or the common malt-ſpirit. If ſome particular art is not uſed in the making this, it will not prove ſo vinous as the malt-ſpirit, but more flat and leſs pungent and acid, though otherwiſe much cleaner taſted, as its eſſential oil is of a leſs naufeous flavour. Whence if good freſh wine leys, abounding in tartar, be duly fermented in the ſolution made thin for that purpoſe, the ſpirit will by that means become much more vinous and briſk, and approach more to the nature of the foreign ſpirits.
After the firſt diſtilling of *moloſſes* ſpirits from the waſh into low wines, it is to be rectified, and in the ſucceeding rectifications proper additions are to be made. Alkaline ſalts, ſo common in the rectifying the malt-ſpirits, muſt be avoided in this caſe, as not at all ſuiting this ſpirit, and the neutral ones only muſt be uſed, ſuch as ſandiver, common decrepitated ſalt, ſal enixum Paracelſi, and the like; but upon the whole nothing ſo conſiderable is to be expected from theſe ſalts, as from a careful rectification in balneo mariæ, without any other admixture; by this alone repeated two or three times with freſh water each time, the ſpirit will at once be made fit for the niceſt uſes.
Where the *moloſſes* ſpirit is brought to the common proof-ſtrength, if it be found not to have enough of the vinoſity in it, it will be very proper to add to it ſome good ſpiritus nitri dulcis; and if the ſpirit be clean worked, it may by this addition alone be made to paſs on ordinary judgments for French brandy.
When newly diſtilled, this ſpirit, like all others, is colourleſs, and limpid as water; but our diſtillers always give it the ſame tort of yellow tinge, which the foreign ſpirits are found to obtain from the caſks they are ſent over in. They have many ways of giving this colour extempore; but the two moſt in uſe are, either by an extract of oak-wood, or by burnt ſugar.
Moloſſes ſpirit coming dearer than that of malt, it is frequently met with baſely adulterated with a mixture of that ſpirit, and indeed ſeldom is to be bought without ſome daſh of it. Many have a way of mixing malt in the fermenting liquor, by this the yield of the whole is greatly increaſed, and the maker may aſſure the buyer that the ſpirit is pure as it ran from the worm.

England is the principal place where this ſpirit is made at this time: it was at one time prepared in great quantities in France, eſpecially on the river Loire; but it is now forbid there, under a ſevere penalty. In Holland alſo they have it not, on account of the high duty laid upon treacle in favour of their own ſugar-bakers.

We meet with very little of *moloſſes* ſpirit reduced to the ſtrength of alcohol or ſpirit of wine, though, when rectified to this ſtate in a proper manner it is very little inferior to the real alcohol of wine, the name of which is ſo well known among us, though the thing itſelf is perhaps never ſeen here. All that we call ſpirit of wine being no other than malt ſpirit reduced to an imperfect alcohol, or a ſpirit almoſt totally inflammable.

Great quantities of *moloſſes* ſpirit are uſed in the adulterating of brandy, rum, and arrack; and great quantities are uſed alone in the making cherry-brandy and other drams by infuſion, in all which many prefer it even to the foreign ſpirits.

In moſt of the nice caſes in our compound diſtillery, the *moloſſes* ſpirit ſupplies the place of a pure and clean malt-ſpirit, which we have not yet the way of producing in the large way to advantage. Our cinnamon, citron, and other fine cordial-waters, are made with it; for the malt ſpirit would give theſe a very diſagreeable flavour.

There is alſo another uſe to which this ſpirit ſerves extremely well, and which even a foreign ſpirit that has any remarkable flavour will not do ſo well in; this is the making the extemporaneous wine, which ſome people are ſo fond of. See *Extemporaneous* WINE.

It gives a yellow ſtain to the hands, or other ſubſtances dipped into it; and may therefore be of uſe in dying. It is poſſible alſo, that the vinegar-makers may find uſe for it in their way; but the moſt advantageous of all its uſes is to the diſtiller himſelf, a quantity of it added to new treacle intended for fermentation will be of great uſe in the proceſs, and increaſe very conſiderably the quantity of ſpirit; but the proportion in regard to the new matter muſt not be too great. Shaw's Eſſay on Diſtillery.

MOLOSSUS, in the *Greek* and *Latin Poetry*, a foot conſiſting of three long ſyllables. As *audiri, cantabant, virtutem*.

It takes it name either from a dance in uſe among the people called *Moloſſi*, or *Epirotæ*; or from the temple of Jupiter *Moloſſus*, where odes were ſung, in which this foot had a great ſhare; or elſe becauſe the march of the *Moloſſi*, when they went to the combat, was compoſed of theſe feet, or had the cadence thereof. The ſame foot was alſo called among the ancients, *Vertumnus, extenſipes, hippius, & cantus*. Dion. iii. p. 475.

MOLTA, or MOLTURA, a duty or toll paid by vaſſals to the lord for grinding their corn at his mill.

MOLTEN *greaſe*, in the *Manege*. See GREASE.

MOLTING, or MOULTING, the falling off or change of hair, feathers, ſkins, horns, or other parts of animals, happening in ſome annually, in others only at certain ſtages of their life.

The generality of beaſts *mult* in the ſpring.

The *molting* of a hawk is called *mewing*.

The *molting* of a deer is the quitting of his horns in February or March.

The *molting* of a ſerpent is the putting off his ſkin. See EXUVIÆ.

MOLUCCA *balm, moluccella*, in *Botany*, a genus of the *didynamia gymnoſpermia* claſs. Its characters are theſe: the flower has a large permanent empalement of one leaf, which is deeply indented at the brim, where it ſpreads open: the flower is of the lip kind, with a ſhort tube; the upper lip is erect, concave and entire; the under lip trifid, the middle ſegment longer than the other; it has four ſtamina, ſituated under the upper lip, two of which are ſhorter than the other; and a germen with four parts, which turn to four angular convex ſeeds, ſitting in the empalement. Linnæus reckons three and Miller two ſpecies; the one a native of the *Moluccа* iſlands, from whence it derives its name; the other grows in Syria.

This plant is a vulnerary, and very good in a phthiſis, being uſed as a tea; no plant is a better ſtrhontriptic. It has the virtues of balm, but ſmells ſomewhat ſtronger.

MOLUCCA *bean*. See BEAN.

MOLUCCA *nuts*. See GUILANDINA and BEAN.

MOLUTA *arma*. See ARMA.

MOLY. The name of this plant is rendered famous by Homer, and has been on this occaſion much inquired into as to its true ſenſe, by the botaniſts of almoſt all times. The old interpreters of Homer all explain this word by the wild rue; and the only reaſon for this is, that at ſome time, probably long after the days of Homer, the people of Cappadocia called the wild rue *moly*. But this plant is wholly different from the *moly* of Homer, which Theophraſtus affirms grew in his time in Areadia, in great plenty, and had a round bulbous root like an onion, and long and graſſy leaves like the ſquill. On the whole, the *moly* of Homer ſeems to have been a ſpecies of allium or GARLIC.

MOLYBDÆNA, *leadwort*, in *Botany*, a name given by ſome authors to the great toothwort, or dentillaria of Rondeletius. See TOOTHWORT.

MOLYBDÆNA is alſo a mineral ſubſtance, called *black-lead*.

MOLYBDIA, in *Natural Hiſtory*, the name of a genus of cryſtals. The word is derived from the Greek μολυβδος, *lead*; and expreſſes cryſtals altered in their figure by particles of that metal. The cryſtals of this genus are of a cubic form, or compoſed of ſix ſides, at right angles, like a die. Of this genus there are three known ſpecies.

MOLYBDOMANTIA, Μολυβδομαντια, in *Antiquity*, a ſpecies of divination, by obſerving the motions, figures, &c. of melted lead.

MOLYZA, μολυζα, a word uſed by the Greek phyſicians to expreſs a head of garlic.

MOMENT, in *Time*, the moſt minute and indiviſible part of duration; or what we otherwiſe call an *inſtant*.

A *moment* ought not to be conceived as the leaſt part of time, but as a termination or limit of time. Maclaurin's Fluxions, vol. i. p. 245.

MOMENTS, in the new doctrine of infinites, denote the infinitely ſmall parts of quantity.

Moments are the ſame with what we otherwiſe call *infinitiſimals*, and *differences*; being the *momentary* increments or decrements of quantity, conſidered as in a continual flux.

Moments are the generative principles of magnitude: they have no determined magnitude of their own; but are only inceptive thereof.

Hence, as it is the ſame thing, if, in lieu of theſe *moments*, the velocities of their increaſes and decreaſes be made uſe of, or the finite quantities proportionable to ſuch velocities; the method of proceeding, which conſiders the motions, changes, or fluxions of quantities, is denominated, by Sir Iſaac Newton, the method of fluxions.

Leibnitz, and moſt foreigners, conſidering theſe infinitely ſmall parts, or infiniteſimals, as the differences of two quantities; and thereby endeavouring to find the differences of quantities, i. e. ſome *moments*, or quantities infinitely ſmall, which, being taken an infinite number of times, ſhall equal given quantities; call theſe *moments*, *differences*; and the method of proceſſure, the *differential calculus*. See CALCULUS *differentialis*.

MOMENT, MOMENTUM, in *Mechanics*, is the ſame with *impetus*; or the quantity of motion in a moving body. See FORCE.

MOMENTUM is ſometimes alſo uſed ſimply for the motion itſelf. *Moment* is frequently defined by the *vis inſita*, or the power by which moving bodies continually change place.

In comparing the motions of bodies, the ratio of their *momenta* is always compounded of the quantity of matter, and the celerity of the moving body; ſo that the *moment* of any ſuch body may be conſidered as a rectangle under the quantity of matter, and the celerity.

And ſince it is certain, that all equal rectangles have their ſides reciprocally proportionable; therefore, if the *moments* of any moving bodies be equal, the quantity of matter in one to that of the other, will be reciprocally as the celerity of the latter to the celerity of the former; and, on the contrary, if the quantities of matter be reciprocally proportionable to the celerities, the *moments* or quantities in each will be equal.

The *moment*, alſo, of any moving body may be conſidered as the aggregate or ſum of all the *moments* of the parts of that body; and therefore where the magnitudes and number of particles are the ſame, and where they are moved with the ſame celerity, there will be the ſame *momenta* of the wholes.

MOMENTARY *motion*. See QUANTITY.

MOMISCUS, a word uſed by ſome as a name of the *dentes molares*, and by others only as a name of that part of thoſe teeth which is near the gums.

MOMORDICA, in *Botany*. See *Male* BALSAM *apple*.

MOMORDICA, *ſtinking*. See *White* BRYONY.

MOMOT, the name of a bird deſcribed by Nieremberg, and ſaid to be an inhabitant of the hot countries. It is of the ſize of a pigeon; its beak is black and crooked, three fingers breadth long, and ſerrated at the edge; its head is blue like the peacock's, and its feet brown; the reſt of the body is of a pleaſant green. But what is moſt ſingular in this bird, is, that it has in its tail one feather much longer than the reſt, which is naked for a great way, and is feathered only at the end. This laſt circumſtance Mr. Ray judges wholly falſe, as no birds have ſingle feathers in their tails, but all that are theſe grow in pairs.

MONACANTHUS, in *Zoology*, a name given by some to the alpheites, or cinedus, a fish approaching to the turdus kind; but differing, in that its back-fin is prickly all along, whereas the fore-part only is so in the turdus.

MONACHELLE, in *Ichthyology*, a name given by some to the fish called, by the oldeſt Greek writers, the *chromys*, and by the later ones, as alſo by the Latin authors on theſe ſubjects, *chromis*. It is properly a ſpecies of the ſparus, and is diſtinguiſhed by Artedi from the others, by the length of the ſecond ray of the belly-fins.

MONAD. See LEIBNITZIAN *philoſophy*.

MONADELPHIA, in *Botany*, the ſixteenth claſs of plants, whoſe ſtamina, or male parts, on account of their filaments running in among one another, are all formed into one body. See FRUCTIFICATION, and *Tab.* I. *Botany*, *Claſs* 16.

The word is formed of the Greek μονος, *ſingle*, and αδελφια, *brotherhood*, or *community*: theſe coalitions of the ſtamina in flowers being underſtood in botany by that term.

This claſs includes five orders, viz. 1. *Pentandria*, comprehending ſuch plants as have five ſtamina, of which order there are four genera; *waltheria*, *lereſia*, *hermannia*, and *melochia*. 2. *Decandria*, whoſe plants have ten ſtamina; of this order there are three genera, viz *connarus*, *bonyna*, and *geranium*. 3. *Endecandria*, with eleven ſtamina, of which order there is only one genus, viz. *brownea*. 4. *Dodecandria*, with twelve ſtamina, containing one genus, viz. *pentapetes*. 5. *Polyandria*, with many ſtamina, including ſeventeen genera, viz. *bombax*, *ſida*, *adanſonia*, *althæa*, *alcea*, *malva*, *lavatera*, *malope*, *urena*, *goſſypium*, *hibiſcus*, *ſtewartia*, *camellia*, *moriſonia*, *ochna*, *malachra*, and *gordonia*. See *Tab.* V. *Botany*, *Claſs* 16.

This is an extremely natural claſs, and there is not one plant uſually allowed to belong to the reſt of this kind, that this character ſeparates, nor one of any other kind that it brings in among them. Tournefort has been guilty of a very great error, in regard to the flowers of the plants of this claſs; he ſays that they are monopetalous, and only divided into five ſegments; but a ſtrict obſervation will ſhew, that they really conſiſt each of five ſeparate petals, which only are joined at the baſe by certain filaments, which together make one body. Hence it follows, that they are ſtrictly and truly pentapetalous, though they fall off together, not ſeparately, on ſhaking the plant.

Though authors in general have kept this claſs of plants together, they have been much divided in their opinions, as to the characters or parts of them, by which they ſhould divide them into genera. Some have had recourſe, on this occaſion, to the ſeed-veſſel; others, finding that inſufficient, have conſulted the leaves. Linnæus uſes the cup of the flower on this occaſion, which is a very eſſential part in this claſs of plants, and ſufficiently different in the different genera.

It is obſerved, that all the plants of this claſs are mucilaginous and emollient, and have great virtues as diuretics, &c. The common marſhmallow deſervedly ſtands at the head of theſe, and is common in the preſcriptions of the phyſicians on theſe occaſions, as well as in many of the ſhop compoſitions, as the ſyrup of marſhmallows and the like.

MONANDRIA, in *Botany*, the firſt claſs of plants which have hermaphrodite flowers, with only one ſtamen each. The word is formed of the Greek μονος, *ſingle*, and ανηρ, *male*. See *Tab.* I. *of Botany*, *Claſs* 1. and FRUCTIFICATION.

The orders belonging to this claſs are two, viz. 1. *Monogynia*, comprehending ſuch plants as have only one ſtyle, of which there are eleven genera, diſtinguiſhed into trilocular, with the pericarpium divided into three loculaments; as the *canna*, *amomum*, *coſtus*, *alpinia*, *maranta*, *curcuma*, *kempferia*, and *ibalia*; and monoſpermous, or thoſe with a ſingle ſeed, as the *boerhaavia*, *ſalicornia*, and *hippuris*. 2. *Digynia*, with two ſtyles, of which order there are four genera, viz. *coriſpermum*, *callitriche*, *bivinum*, and *cinna*. See *Tab.* III. *Botany*, *Claſs* 1.

MONARCHICI, in *Church Hiſtory*, heretics towards the end of the ſecond century, who allowed but one perſon in the Godhead, and maintained that the Father, the creator of all things, had united himſelf to the human nature of Chriſt; whence they were called *Monarchians*; and they alſo taught that the father was crucified: on this account they were denominated *Patropaſſians*.

MONARCHY, μοναρχια, a large ſtate governed by one; or a ſtate where the ſupreme power is lodged in the hands of a ſingle perſon.

The word comes from the Greek μοναρχω, *one who governs alone*; formed of μονος, *ſolus*, and αρχω, *imperium, power uturus*.

Of the three forms of government, viz. DEMOCRACY, ARISTOCRACY, and *monarchy*, the laſt is the moſt powerful, all the ſinews of government being knit together, and united in the hand of the prince; but then there is imminent danger of his employing that ſtrength to improvident or oppreſſive purpoſes. As a democracy is the beſt calculated to direct the end of a law, and an ariſtocracy to invent the means by which that end ſhall be obtained, a *monarchy* is moſt fit for carrying thoſe means into execution.

The moſt ancient *monarchy* was that of the Aſſyrians, which was founded ſoon after the deluge. We uſually reckon four grand or univerſal *monarchies*; the Aſſyrian, Perſian, Grecian, and Roman; though St. Auguſtine makes them but two, viz. thoſe of Babylon and Rome. Belus is placed at the head of the ſeries of Aſſyrian kings who reigned at Babylon, and is by profane authors eſteemed the founder of it, and by ſome the ſame whom the ſcriptures call Nimrod. The principal Aſſyrian kings after Belus were Ninus, who built Nineveh, and removed the ſeat of empire to it; Semiramis, who, diſguiſing her ſex, took poſſeſſion of the kingdom inſtead of her ſon, and was killed and ſucceeded by her ſon Ninyas; and Sardanapalus, the laſt of the Aſſyrian monarchs, and more effeminate than a woman. After his death the Aſſyrian empire was ſplit into three ſeparate kingdoms; viz. the Median, Aſſyrian, and Babylonian. The firſt king of the Median kingdom was Arbaces; and this kingdom laſted till the time of Aſtyages, who was ſubdued and diveſted of his kingdom by Cyrus. In the time of Cyrus there aroſe a new and ſecond *monarchy*, called the Perſian; which ſtood upwards of two hundred years, from Cyrus, who firſt reign began A. M. 3468, to Darius Codomannus, who was conquered by Alexander, and the empire tranſlated to the Greeks A. M. 3674. The firſt monarch was Cyrus, founder of the empire; the ſecond Cambyſes, the ſon of Cyrus. 3. Smerdis. 4. Darius, the ſon of Hyſtaſpis, who reigned 521 years before Chriſt. 5. Xerxes, who reigned 485 years before Chriſt. 6. Artaxerxes Longimanus, who reigned 464 years before Chriſt. 7. Xerxes the ſecond. 8. Ochus, or Darius, called Nothus, 424 years before Chriſt. 9. Artaxerxes Mnemon, 405 years before Chriſt. 10. Artaxerxes Ochus, 359 years before Chriſt. 11. Arſes, 338 years before Chriſt. 12. Darius Codomannus, 336 years before Chriſt, who was defeated by Alexander the Great, and deprived of his kingdom and life about 331 years before Chriſt: the dominion of Perſia after his death was tranſlated to the Greeks. The third *monarchy* was the Grecian. As Alexander when he died did not declare who ſhould ſucceed him, there ſtarted up as many kings as there were commanders. At firſt they governed the provinces, that were divided among them, under the title of viceroys; but when the family of Alexander the Great was extinct, they took upon them the name of kings. Hence, in proceſs of time, the whole empire of Alexander produced four diſtinct kingdoms; viz. 1. The Macedonian, the kings of which, after Alexander, were Antipater, Caſſander, Demetrius Poliorcetes, Seleucus Nicanor, Meleager, Antigonus Doſon, Philip, and Perſeus, under whom the Macedonian kingdom was reduced to the form of a Roman province. 2. The Aſiatic kingdom, which, upon the death of Alexander, fell to Antigonus, comprehending that country now called Natolia, together with ſome other regions beyond Mount Taurus. From this kingdom proceeded three leſſer ones; viz. that of Pergamus, whoſe laſt king, Attalus, appointed the Roman people to be his heir; Pontus, reduced by the Romans into the form of a province, when they had ſubdued the laſt king, Mithridates. 3. The Syrian, of whoſe twenty-two kings the moſt celebrated were Seleucus Nicanor, founder of the kingdom, Antiochus Deus, Antiochus the Great, Antiochus Epiphanes, and Tigranes, who was conquered by the Romans under Pompey; and Syria was reduced into the form of a Roman province. 4. The Egyptian, which was formed by the Greeks in Egypt, and flouriſhed near two hundred and forty years under twelve kings; the principal of whom were Ptolemy Lagus, its founder; Ptolemy Philadelphus, founder of the ALEXANDRIAN *library*; and queen Cleopatra, who was overcome by Auguſtus; in conſequence of which Egypt was added to the dominion of the Romans. The fourth *monarchy* was the Roman, which laſted two hundred and forty-four years, from the building of the city, until the time when the royal power was abrogated. The kings of Rome were Romulus its founder, Numa Pompilius, Tullus Hoſtilius, Ancus Martius, Tarquinius Priſcus, Servius Tullius, and Tarquin the Proud, who was baniſhed, and with whom terminated the regal power. Hollberg's Introd. to Univ. Hiſt. by Dr. Sharpe, p. 85, &c.

There ſeems, in reality, no neceſſity to make the Medes, Perſians, and Greeks, ſucceed to the whole power of the Aſſyrians, to multiply the number of the *monarchies* at

was the same empire still, and the several changes that happened in it, did not constitute different *monarchies*. Thus the Roman empire was successively governed by princes of different nations, yet without any new *monarchy* being formed thereby. Rome, therefore, may be said to have immediately succeeded Babylon in the empire of the world. See EMPIRE.

Of *monarchies*, some are *absolute* and *despotic*, where the will of the monarch is uncontrolable; as Denmark, &c. others are *limited*, where the prince's authority is restrained by laws, and part of the supreme power lodged in other hands; as in England. See GOVERNMENT.

Some *monarchies*, again, are *hereditary*, where the succession devolves immediately from father to son; and others are *elective*, where, on the death of the *monarch*, his successor is appointed by election; as in Poland.

According to Hobbes, *monarchy*, as well as aristocracy, derives all its authority from the people, who transfer all their right, v. gr. the supreme power, by a plurality of suffrages, &c. to some one person called a *monarch*; so that whatever the people could have done before this translation, may be now rightfully done by him to whom the translation is made. This done, the people are no longer to be looked upon as a body, but a dissolved multitude; because they were only one by virtue of the supreme power, which they have now transferred to another.

Nor can the *monarch*, according to this author, oblige himself by any covenants, to any person, for the authority he has received; because he receives the power from the people, which, as soon as that is done, ceases to be a body; and the body ceasing, the obligation to the body ceases of course. The people, therefore, are obliged to pay obedience to the *monarch*, by virtue of those covenants, whereby they mutually oblige themselves to what the people, as a body, enjoin to be done.

He argues, farther, that as a *monarch* cannot be obliged by any covenants; so neither can he do any injury to his subjects; an injury being nothing else but a breach of covenant: and where there is no covenant, there can be no breach of one. De Cive, c. 8. See HOBBISM.

Fifth-MONARCHY *men*, in the *Ecclesiastical History of England*, were a set of wrong-headed and turbulent enthusiasts who arose in the time of Cromwell, and who expected Christ's sudden appearance upon earth to establish a new kingdom; and, acting in consequence of this illusion, aimed at the subversion of all human government. Burnet's Hist. of his Own Times, vol. 1. p. 67.

MONARDA, *Oswego-tea* and *American field bush*, in *Botany*, a genus of the *diandria monogynia* class. Its characters are these: the flower has a cylindrical empalement of one leaf, cut into five equal parts at the brim; the flower has one petal, which is of the lip kind, and divided at the top into two lips; the upper lip is narrow, entire, and erect; the under lip broad, trifid, and reflexed; it has two bristly stamina, the length of the upper lip; in the bottom of the tube is situated a four-pointed germen, supporting a slender style, involved with the stamina, and crowned by an acute bifid stigma; the germen turns to four naked seeds, inclosed in the empalement. Linnæus enumerates five, and Miller three, species, natives of North America.

MONASTERII *provisor*. See PROVISOR.

MONASTERY, a convent, or house built for the reception of religious; whether it be ABBEY, PRIORY, NUNNERY, or the like.

MONASTERY is only properly applied to the houses of monks, mendicant friars, and nuns. The rest are more properly called *religious houses*.

For the origin of *monasteries*, see MONASTIC and MONK. The houses belonging to the several religious orders, which obtained in England and Wales, were cathedrals, colleges, abbies, priories, preceptories, commandries, hospitals, frieries, hermitages, chantries, and free chapels. These were under the direction and management of various officers. The dissolution of houses of this kind began to early as the year 1312, when the TEMPLARS were suppressed; and in 1323 their lands, churches, advowsons, and liberties, here in England, were given, by 17 Ed. II. stat. 3. to the prior and brethren of the hospital of St. John at Jerusalem. In the years 1390, 1437, 1441, 1459, 1497, 1505, 1508, and 1515, several other houses were dissolved, and their revenues settled on different colleges in Oxford and Cambridge. Soon after the last period, cardinal Wolsey, by licence of the king and pope, obtained a dissolution of above thirty religious houses, for the founding and endowing his colleges at Oxford and Ipswich. About the same time a bull was granted by the same pope to cardinal Wolsey, to suppress *monasteries*, where there were not above six monks, to the value of eight thousand ducats a year, for endowing Windsor, and King's College in Cambridge; and two other bulls were granted to cardinals Wolsey and Campeius, where there were less than twelve monks, and to annex them to the greater *monasteries*; and another bull to the same cardinals to enquire about abbies, to be suppressed, in order to be made cathedrals. Although nothing appears to have been done in consequence of these bulls, the motive which induced Wolsey, and many others, to suppress these houses, was the desire of promoting learning; and archbishop Cranmer engaged in it with a view of carrying on the Reformation. There were other causes that concurred to bring on their ruin: many of the religious were loose and vicious; the monks were generally thought to be, in their hearts, attached to the pope's supremacy; their revenues were not employed according to the intent of the donors; many cheats in images, feigned miracles, and counterfeit relics, had been discovered, which brought the monks into disgrace; the Observant friars had opposed the king's divorce from queen Catharine; and these circumstances operated, in concurrence with the king's want of a supply, and the people's desire to save their money, to forward a motion in parliament, that in order to support the king's state, and supply his wants, all the religious houses might be conferred upon the crown, which were not able to spend above 200*l.* a year; and an act was passed for that purpose, 27 Hen. VIII. c. 28. By this act about three hundred and eighty houses were dissolved, and a revenue of 30 or 32,000*l.* a year came to the crown; besides about 100,000*l.* in plate and jewels. The suppression of these houses occasioned discontent, and at length an open rebellion: when this was appeased, the king resolved to suppress the rest of the *monasteries*, and appointed a new visitation; which caused the greater abbies to be surrendered apace; and it was enacted by 31 Hen. VIII. c. 13. that all *monasteries*, &c. which have been surrendered since the fourth of February, in the twenty-seventh year of his majesty's reign, and which hereafter shall be surrendered, shall be vested in the king. The knights of St. John of Jerusalem were also suppressed by the 32 Hen. VIII. c. 24. The suppression of these greater houses by these two acts, produced a revenue to the king of above 100,000*l.* a year, besides a large sum in plate and jewels. The last act of dissolution in this king's reign was the act of 37 Hen. VIII. c. 4. for dissolving colleges, free chapels, chantries, &c. which act was farther enforced by 1 Ed. VI. c. 14. By this act were suppressed ninety colleges, a hundred and ten hospitals, and two thousand three hundred and seventy-four chantries and free chapels. The number of houses and places suppressed from first to last, so far as any calculations appear to have been made, seems to be as follows:

Of lesser *monasteries*, of which we have the valuation	374
Of greater *monasteries*	186
Belonging to the Hospitallers	48
Colleges	90
Hospitals	110
Chantries and free chapels	2374
Total	3182

Besides the friars houses, and those suppressed by Wolsey, and many small houses, of which we have no particular account.

The sum total of the clear yearly revenue of the several houses at the time of their dissolution, of which we have any account, seems to be as follows:

	l.	*s.*	*d.*
Of the greater *monasteries*	104919	13	3½
Of all those of the lesser *monasteries*, of which we have the valuation	29702	1	10½
Knights Hospitallers head house in London	2385	12	8
We have the valuation of only 28 of their houses in the country	3026	9	5
Friars houses, of which we have the valuation	751	2	0½
Total	140784	19	3½

If proper allowances are made for the lesser *monasteries*, and houses not included in this estimate, and for the plate, &c. which came into the hands of the king by the dissolution, and for the value of money at that time, which was at least six times as much as at present; and also consider that the estimate of the lands was generally supposed to be much under the real worth, we must conclude their whole revenues to have been immense.

It doth not appear that any computation hath been made of the number of persons contained in the religious houses.

Those

Thoſe of the leſſer *monaſteries* diſſolved by 27 Hen. VIII. were reckoned at about -	10000
If we ſuppoſe the colleges and hoſpitals to have contained a proportionable number, theſe will make about - - - - -	5347
If we reckon the number in the greater *monaſteries*, according to the proportion of their revenues, they will be about 35000; but as probably they had larger allowances in proportion to their number than thoſe of the leſſer *monaſteries*, if we abate upon that account 5000. they will then be - - - - -	30000
One for each chantry and free chapel -	2374
Total	47721

But as there were probably more than one perſon to officiate in ſeveral of the free chapels, and there were other houſes which are not included within this calculation, perhaps they may be computed in one general eſtimate at about 50,000. As there were penſions paid to almoſt all thoſe of the greater *monaſteries*, the king did not immediately come into the full enjoyment of their whole revenues; however, by means of what he did receive, he founded ſix new biſhopricks, viz. thoſe of Weſtminſter (which was changed by queen Elizabeth into a deanry, with twelve prebends, and a ſchool), Peterborough, Cheſter, Glouceſter, Briſtol, and Oxford. And in eight other ſees he founded deanries and chapters, by converting the priors and monks into deans and prebendaries, viz. Canterbury, Wincheſter, Durham, Worceſter, Rocheſter, Norwich, Ely, and Carliſle. He founded alſo the colleges of Chriſt-church in Oxford, and Trinity in Cambridge, and finiſhed King's college there. He likewiſe founded profeſſorſhips of divinity, law, phyſic, and of the Hebrew and Greek tongues, in both the ſaid univerſities. He gave the houſe of Grey Friars, and St. Bartholomew's hoſpital, to the city of London; and a perpetual penſion to the poor knights of Windſor, and laid out great ſums in building and fortifying many ports in the channel. It is obſervable, upon the whole, that the diſſolution of theſe houſes was an act, not of the church, but of the ſtate, in the period preceding the Reformation, by a king and parliament of the Roman catholic communion, in all points except the king's ſupremacy; to which the pope himſelf, by his bulls and licences, had led the way. See Tanner's Notitia Monaſtica; and for an abſtract, Burn's Eccl. Law, art. *Monaſteries*.

MONASTIC, ſomething belonging to monks, or the monkiſh life.

The *monaſtic* profeſſion is a kind of civil death, which in all worldly matters has the ſame effect with the natural death.

The council of Trent, &c. fix fifteen years for the age at which a perſon may be admitted into the *monaſtical* ſtate.

St. Antony is the perſon who, in the fourth century, firſt inſtituted the *monaſtic* life; as St. Pachomius, in the ſame century, is ſaid to have firſt ſet on foot the cœnobitic life, i. e. regular communities of religious.

In a ſhort time, the deſarts of Egypt became inhabited with a ſet of ſolitaries, who took upon them the *monaſtic* profeſſion. See ANACHORET, HERMIT, &c. St. Baſil carried the monkiſh humour into the Eaſt, where he compoſed a rule which afterwards obtained through a great part of the Weſt.

In the eleventh century, the *monaſtic* diſcipline was grown very remiſs. St. Odo firſt began to retrieve it in the monaſtery of Cluny: that monaſtery, by the conditions of its erection, was put under the immediate protection of the holy ſee; with a prohibition to all powers, both ſecular and eccleſiaſtical, to diſturb the monks in the poſſeſſion of their effects, or the election of their abbot. In virtue hereof, they pleaded an exemption from the juriſdiction of the biſhop, and extended this privilege to all the houſes dependent on Cluny. This made the firſt congregation of ſeveral houſes under one chief immediately ſubject to the pope, ſo as to conſtitute one body; or, as they now call it, one *religious order*. Till then, each monaſtery was independent, and ſubject to the biſhop. See MONK.

MONBIN, in *Botany*. See *Jamaica* PLUM.

MOND. See MOUND.

MONDAY, *dies lunæ*. See PLOUGH.

MONEDULA, in *Ornithology*. See JACKDAW.

MONEMERION, *pierrogeny*, among the ancient Romans, a ſhew, according to ſome, wherein none but tame beaſts were expoſed to view.

Others will have it to be a ſhew of one day's continuance.

MONETÆ *pes*. See PES.

MONETAGIUM, MONETAGE, or MINTAGE, the right or privilege of COINING money.

MONETALES *triumviri*. See TRIUMVIRI.

MONETARIUS, or MONEYER, a name which antiquaries and medaliſts give to thoſe who ſtruck the ancient coins, or monies.

Many of the old Roman, &c. coins have the name of the *monetarius*, either written at length, or at leaſt the initial letters of it. See MEDAL.

MONEY, or MONY, *moneta*, a piece of metal marked for coin, with the arms of a prince, or ſtate, who make it circulate or paſs, at a fixed rate, for things of different value; to facilitate the buſineſs of commerce.

Paulus the lawyer defines *money*, a thing ſtamped with a public coin, and deriving its uſe and value from its impreſſion, rather than its ſubſtance.

Monſ. Boizard defines *money*, a piece of matter to which public authority has affixed a certain value and weight; to ſerve as a medium in commerce.

Or, *money* may be defined an univerſal medium, or common ſtandard, by compariſon with which the value of all merchandize may be aſcertained; or, it is a ſign, which repreſents the reſpective values of all commodities. Metals are well calculated for this ſign, becauſe they are durable, and are capable of many ſubdiviſions; and a precious metal is ſtill better calculated for this purpoſe, becauſe it is the moſt portable. A metal is alſo the moſt proper for a common meaſure, becauſe it can eaſily be reduced to the ſame ſtandard in all nations; and every particular nation fixes on it its own impreſſion, that the weight and ſtandard, wherein conſiſts the intrinſic value, may both be known by inſpection only. And as *money* is the medium of commerce, it is the king's prerogative, as the arbiter of domeſtic commerce, to give it authority, or make it current. It is evident, that, as the quantity of precious metals increaſes, i. e. the more of them there is extracted from the mine, this univerſal medium, or common ſign, will ſink in value, and become leſs precious. Above a thouſand millions of bullion are calculated to have been imported into Europe from America within leſs than three centuries; and the quantity is daily increaſing. The conſequence is, that more *money* muſt be given now for the ſame commodity than was given a hundred years ago. And if any accident was to diminiſh the quantity of gold and ſilver, their value would proportionably riſe.

The æra of the invention of *money* is not eaſy to be ſettled. There is no room to doubt, but that, in the earlieſt ages, the ordinary way of traffic among men was, by trucking, or exchanging commodity for commodity. Thus, in Homer, Glaucus's golden armour was valued at one hundred oxen; and Diomedes's armour at ten.

But in courſe of time it was found neceſſary, in the way of commutative juſtice, to have ſome common meaſure, or ſtandard, according to which all other things ſhould be eſtimated. This, as ſome gather from Joſephus, was firſt invented by Cain; though the firſt tidings we hear of it are, in the time of Abraham, who paid four hundred ſhekels for a burying-place.

The Greeks refer the invention of *money* to Hermodice, wife of king Midas; and the Latins to Janus. *Money* being a common meaſure for reducing wares to a balance, it was called, by the Greeks, *nomiſma*; not from king Numa, but from *nomos*, as being eſtabliſhed by law; by the Latins it was called *pecunia*; either becauſe the wealth of thoſe days conſiſted in their cattle; or, as Pliny will have it, becauſe their firſt coin was ſtamped with the figure of a cow: they alſo call it *moneta*, a *monendo*, as Suidas obſerves; becauſe, when the Romans were in want of *money*, Juno admoniſhed them to uſe juſtice, and there ſhould be no want of *money*: the effect whereof when they had found, the was ſurnamed *Juno Moneta*, and *money* was coined in her temple. In proceſs of time, *Money* herſelf was made a goddeſs, and inſhrined by the name of *Dea Pecunia*, under the figure of a woman holding a balance in one hand, and a cornucopiæ in the other. On the foot *money* now ſtands, it may be divided into *real*, or *effective*, and *imaginary*.

MONEY, *real*, includes all coins, or ſpecies, of gold, ſilver, copper, and the like; which have courſe in commerce, and do really exiſt. Such are *guineas*, *crowns*, *piſtoles*, *pieces of eight*, *ducats*, &c. which ſee under their proper heads; as alſo under COIN.

Real money, civilians obſerve, has three eſſential qualities; viz. *matter*, *form*, and *weight* or *value*. For *matter*, copper is that thought to have been firſt coined; afterwards, ſilver; and, laſtly, gold, as being the moſt beautiful, ſcarce, cleanly, divilible, and pure, of all metals.

The degrees of goodneſs are expreſſed in gold by carats, and in ſilver by penny-weights, &c. for there are ſeveral reaſons for not coining them pure, and without alloy. See COINAGE.

Among the ancient Britons, iron rings, or, as ſome ſay, iron plates, or tin plates and rings, were uſed for *money*. Among the Lacedæmonians, iron bars, quenched with vinegar,

vinegar, intended that they might not ſerve for any other uſe. Seneca obſerves, that there was anciently ſtamped *money* of leather, *certum forma publica impreſſum*; and the ſame thing was put in practice by Frederic II. at the ſiege of Milan; to ſay nothing of an old tradition among ourſelves, that, in the confuſed times of the barons wars, the like was done in England. In 1360, king John of France, who agreed to pay our Edward III. for the raunſom of his perſon three millions of gold crowns, was reduced to the neceſſity of paying for the neceſſaries of his houſhold in leather *money*, in the middle whereof there was a little nail of ſilver. The Hollanders, we know, coined great quantities of paſteboard in the year 1574. Numa Pompilius made *money* of wood and leather; nor does it appear, that the Romans were much acquainted with the art of ſtriking *money* in metal, during the time of their kings. There is reaſon to believe, that both gold and ſilver *money* were very early in uſe in Egypt and Aſia, and thence ſoon afterwards introduced into Carthage and Greece. From Greece it was brought to Rome, and thence gradually weſtward into all the Roman provinces. The firſt ſilver *money* coined by the Romans was in the year of Rome 484, and their firſt gold *money* in 546.

With regard to the materials of Engliſh *money*, Sir Edward Coke lays it down, that the *money* of England muſt either be of gold or ſilver; and none other was ever iſſued by the royal authority till 1672, when copper farthings and half-pence were coined by king Charles the Second, and ordered by proclamation to be current in all payments, under the value of ſixpence, and not otherwiſe. But this copper coin is not upon the ſame footing with the other in many reſpects, particularly with regard to the offence of counterfeiting it.

As to the *form of money*, it has been more various than the matter. Under this are comprehended the weight, figure, impreſſion, and value.

For the *impreſſion*, the Jews, though they deteſted images, yet ſtamped on the one ſide of their ſhekel, the golden pot which had the manna; and on the other, Aaron's rod; the Dardans, two cocks fighting; Alexander, as is held by ſome, his horſe Bucephalus: though this may be doubted of, becauſe the horſe is found as frequently on the coins of ſeveral of the kings of Macedon, his predeceſſors, as his. The Athenians ſtamped their coins with an owl, or an ox; whence the proverb on bribed lawyers, *bos in lingua*; the people of Ægina with a tortoiſe; whence that other ſaying, *Virtutem & ſapientiam vincunt teſtudines*. For the Romans, the monetarii ſometimes impreſſed the images of men that had been eminent in their families, on their coins; but no living man's head was ever ſtamped on a Roman coin till after the fall of the commonwealth; after that time, they bore the emperor's head on one ſide; and, from this time, the practice of ſtamping the prince's image on coins has obtained among all civilized nations, the Turks and other Mahometans excepted; who, in deteſtation of images, inſcribe only the prince's name, with the year of the tranſmigration of their prophet.

As to the impreſſion of Britiſh *money*, the ſtamping thereof is the unqueſtionable prerogative of the crown; for though divers biſhops and monaſteries had formerly the privilege of coining *money*, yet, as Sir Matthew Hale obſerves, this was uſually done by ſpecial grant from the king, or by preſcription, which ſuppoſes one; and, therefore, was derived from, and not in derogation of, the royal prerogative. Beſides, they had only the profit of the coinage, and not the power of inſtituting either the impreſſion or denomination; but had uſually the ſtamp ſent them from the exchequer. The denomination, or the value for which the coin is to paſs current, is likewiſe in the breaſt of the king; and if any unuſual pieces are coined, that value muſt be aſcertained by proclamation. In order to fix the value, the weight and the fineneſs of the metal are to be taken into conſideration together. When a given weight of gold or ſilver is of a given fineneſs, it is then of the true ſtandard, and called ſterling metal; and of this ſterling metal all the coin of the kingdom muſt be made, by 25 Edw. III. c. 13. ſo that the king's prerogative ſeems not to extend to the debaſing or enhancing the value of the coin, below or above the ſterling value; though Sir Matthew Hale appears to be of another opinion. The king *may alſo*, by his proclamation, legitimate foreign coin, and make it current here; declaring at what value it ſhall be taken in payments. But this, judge Blackſtone apprehends, ought to be by compariſon with the ſtandard of our own coin; otherwiſe the conſent of parliament will be neceſſary. There is now no legitimated *money*. The king may alſo at any time decry, or cry down any coin of the kingdom, and make it no longer current.

As to the *figure of money*, it is either round, as in England; multangular, or irregular, as in Spain; ſquare, as in ſome parts of the Indies; or nearly globular, as in moſt of the reſt.

After the arrival of the Romans in this iſland, the Britons imitated them, coining both gold and ſilver, with the images of their kings ſtamped on them: when the Romans had ſubdued the kings of the Britons, they alſo ſuppreſſed their coins, and brought in their own, which were current here from the time of Claudius to that of Valentinian the Younger, this being about the ſpace of five hundred years.

Mr Camden obſerves, that the moſt ancient Engliſh coin he had known, was that of Ethelbert, king of Kent, the firſt Chriſtian king in the iſland; in whoſe time all *money* accounts began to paſs by the names of *pounds*, *ſhillings*, *pence*, and *mancuſes*.

The penny ſeems borrowed from the Latin *pecunia*, or rather from *pondo*, on account of its juſt weight, which till king Edward the third's reign contained as much ſilver as about three pence of our *money*: theſe were coarſely ſtamped with the king's image on the one ſide, and either the miſt-maſter's name, or the city's where it was coined, on the other: five of theſe pence made their ſcilling, probably ſo called from *ſcillingus*, which the Romans uſed for the fourth part of an ounce; forty of theſe ſcillings made their pound, and four hundred of theſe pounds were a legacy, or a portion for a king's daughter; as appears by the laſt will of king Alfred.

By theſe names they tranſlated all ſums of *money* in their old Engliſh teſtament; talents by *pounds*; judas's thirty pieces of ſilver by *thirtie ſcillings*; tribute-*money*, by *penincg*; and the mite by *feorthling*.

But, it muſt be obſerved, they had no other real *money*, but pence only; the reſt being imaginary *monies*, i. e. names of numbers, or weights: thirty of theſe pence made a mancus, which ſome take to be the ſame with a mark; manca, as appears by an old MS. was *quinque ſexcuntæ*. Theſe mancæ, or mancuſes, were reckoned both in gold and ſilver; for in the year 680, we read, that Ina, king of the Weſt Saxons, obliged the Kentiſh men to buy their peace at the price of thirty thouſand mancas of gold. In the notes on king Canute's laws we find this diſtinction, that *mancuſa* was as much as a mark of ſilver; and *manca* a ſquare piece of gold, valued at thirty pence. See MANCUS.

The Danes introduced a way of reckoning *money* by ores, *per oras*, mentioned in Domeſday book; but whether they were a diſtinct coin, or a certain ſum, does not plainly appear: this, however, may be gathered from the abbey-book of Burton, that twenty ores were equivalent to two marks.

They had alſo a gold coin called *bizantine*, or *bezant*, as being coined at Conſtantinople, then called *Byzantium*; the value of which coin is not only now loſt, but was ſo entirely forgotten, even in the time of king Edward III. that, whereas the biſhop of Norwich was fined a bizantine of gold, to be paid the abbot of St. Edmundſbury, for infringing his liberty (as it had been enacted by parliament, in the time of the Conqueror), no man, then living, could tell how much it was; ſo that it was referred to the king, to rate how much he ſhould pay; which is the more unaccountable, becauſe, but a hundred years before, two hundred thouſand bezants were exacted by the ſoldan, for the raunſom of St. Lewis of France; which were then valued at one hundred thouſand livres.

Though the coining of *money* be a ſpecial prerogative of the king, yet the ancient Saxon princes communicated it to their ſubjects; inſomuch that in every good town there was, at leaſt, one mint, but at London eight; at Canterbury four for the king, two for the archbiſhop, one for the abbot at Winchcſter, ſix at Rocheſter, at Haſtings two, &c.

The Norman kings continued the ſame cuſtom of coining only pence, with the prince's image on one ſide, and on the other the name of the city where it was coined, with a croſs ſo deeply impreſſed, that it might be eaſily parted, and broken into two halves, which, ſo broken, they called half-pence; or into four parts, which they called *farthings*, or FARTHINGS.

In the time of king John, *money*, coined in the eaſt parts of Germany, came in ſpecial requeſt in England, on account of its purity, and was called *eaſterling money*, as all the inhabitants of thoſe parts were called *Eaſterlings*; and, ſhortly after, ſome of thoſe people, ſkilled in coining, were ſent for hither, to bring the coin to perfection; which, ever ſince, has been called STERLING, from *eaſterling*.

King Edward I. who firſt aſſiſted the meaſure of an ell by the length of his arm, herein imitating Charles the Great,

Great, was the first, also, who established a certain standard for the coin, which is expressed to this effect by Greg. Rockley, mayor of London, and mint-master. "A pound "of money contained twelve ounces: in a pound there "ought to be eleven ounces, two esterlings, and one "farthing; the rest allays: the fine pound ought to weigh "twenty shillings and three pence in account and weight; "the ounce ought to weigh twenty pence, and a penny "twenty-four grains and a half. Note, that eleven "ounces two pence sterling ought to be of pure silver, "called *halfpenny*; and the master must add, of other "weight, fourteen pence halfpenny farthing, if the "silver be so pure."

About the year 1320, the states of Europe first began to coin gold; and, among the rest, our king Edward III. The first pieces he coined were called *Florences*, as being coined by Florentines; afterwards he coined nobles; then rose-nobles, current at six shillings and eight pence; half-nobles, called *halfpennies*, at three shillings and four pence of gold; and quarters at twenty pence, called *farthings of gold*. The succeeding kings coined rose-nobles, and double rose-nobles, great sovereigns, and half Henry nobles, angels, and shillings.

King James I. coined units, double crowns, Britain crowns; then crowns, half-crowns, &c.

TABLES of GOLD and SILVER, composed from the authority of Mr. Lowndes, who inspected the original indentures, and from bishop Fleetwood.

1 W. & M.	I do not find any alteration in the standard of the gold or silver down to the pre-							
Queen Anne	sent time; 22 Carats fine and 2 alloy is the ℔ of gold, and 11 oz. 2 dwts fine, and							
	18 dwts alloy, the standard ℔ of silver; and the division of the pound gold continues							
	the same; that is to say, into 44 guineas ½, and the silver into the usual number of							15 21
George I.	crowns, &c. But the guineas have varied in the nominal value several times, rising							
	up to xxix. and declining to xxi, the present current value; but never have been re-							
George II.	duced again to their intended level of xxii, nor indeed ought, when compared with							
	the Portugal pieces of 3l. 12s. or 3l. 16s. it appears to be better worth xxii.							

	To the ℔. Troy.	
Portugal -	£3 12 - 13	£46 16 0
English guineas -	1 1 - 44½	46 14 6
		00 1 6
And the Portuguese standard worse ¼ grain		00 2 6
Total worse ℔ Troy in standard and tale -		00 4 0

This, with the difference in point of exactness in coining, wherein the Portugal is much more defective than the English coins, may be very good reasons for their being refused in payments in any of the receipts of the public revenue; but answer very well the purpose of those who benefit by the irregularity, in trading with the heavier and passing off the lighter by tale; and which, if they can turn into guineas or heavy silver, make another gain.

How our standard is proportioned to that of other countries, and thence what the true par of exchange is between us, see COIN.

A TABLE exhibiting the standard, weight, value, and a comparative view of English GOLD MONEY from King William I. Ann. 1066, to King George III. Ann. 1761.

Years of the kings and queens reigns, or the states of the several successions.	Standard of the gold at each period.		Value or No. of pounds, &c. the ℔ Troy of stand. gold has been coined into.	Value or number of shillings, &c. the ℔ Troy has been coined into.	Value of 22 shillings of coined gold in each period in our present money.	Proportions of the same number of shillings in our present and their standard.	Proportions between the current value of the ℔. Troy of standard silver and standard gold.	Proportion of fine silver to fine gold at each period.
	Fine gold	Alloy.

The king, by proclamation, may at any time prohibit all his ſubjects, not exceeding one year, to lend or advance *money* to any foreign prince or ſtate, without licence under the great or privy ſeal; and if any perſon knowingly offend in the premiſes, he ſhall forfeit treble the value of the *money* lent, &c. two-thirds to the king, and the other to the informer; but perſons may deal in foreign ſtocks, or be intereſted in any bank abroad, eſtabliſhed before iſſuing his majeſty's proclamation. Stat. 3 Geo. II. c. 5.

MONEY, *falſe*, or *baſe*, is either that ſtruck by an unqualified perſon, and of unſtatutable metals; or that which has loſt of its weight, either by being clipped on the corners, or filed on the edges; or, laſtly, by having ſome of its ſurface eaten off; if gold, by aqua regia; if ſilver, by aqua fortis.

Another kind of baſe *money* is that made of pieces of iron, copper, or other metal, covered on each ſide with a thin plate or leaf of gold or ſilver, neatly ſoldered and joined round the edges, and ſtruck, like other coin, with figures, legends, &c. only to be diſtinguiſhed from them by the touch, and weight, and ſound.

MONEY, *imaginary*, or MONEY *of account*, is that which has never exiſted, or, at leaſt, which does not exiſt in real ſpecies, but is a denomination invented, or retained, to facilitate the ſtating of accounts, by keeping them ſtill on a fixed footing, not to be changed, like current coins, which the authority of the ſovereign ſometimes raiſes, or lowers, according to the exigencies of ſtate. Of which kinds are, *pounds*, *livres*, *marks*, *maravedies*, &c. See ACCOUNT.

Money of account, according to M. Boizard, is a ſum of *money*, or a certain number of ſpecies which may change in ſubſtance and quantity, but never in quality. Thus fifty pounds conſiſts of fifty pieces called *pounds*, which are not real, but may be paid in ſeveral real ſpecies, as in guineas, crowns, ſhillings, &c. which are changeable, as guineas, v. gr. which are ſometimes higher, ſometimes lower. For the *money* current and of account in different countries, ſee COIN.

MONEY-*bills*, in *Parliamentary Language*, comprehend all bills, by which *money* is directed to be raiſed upon the ſubject, for any purpoſe or in any ſhape whatſoever; either for the exigencies of government, and collected from the kingdom in general, as the LAND-TAX; or for private benefit, and collected in any particular diſtrict, as by turnpikes, pariſh-rates, and the like. With reſpect to theſe bills, the commons are ſo reaſonably jealous of their privilege of framing new taxes for the ſubject, that they will not ſuffer the other houſe to exert any other power but that of rejecting; they will not permit the leaſt alteration or amendment to be made by the lords to the mode of taxing the people by bills of this nature.

MONEY, *arri*, *chimney*, *machine*, *poll*, *preſt*, *preſtation*, *ſalvage*, *ſhip*, and *trophy*. See the ſeveral articles.

MONEY-*wort*, *nummularia*, in *Botany*, a ſpecies of the LOOSESTRIFE. It is a perennial plant, growing in moiſt ſhady places in many parts of England, ſo is not cultivated in gardens. It flowers from May to near the end of ſummer. It is one of the principal vulneraries; and, drank in wine, cures dyſenteries, weakneſſes, fluxes, and humidities of the belly; it is alſo good for vomiting of blood, uterine fluxes, internal wounds or ulcers, eſpecially of the lungs. Boerhaave conſiders it as ſimilar to a mixture of ſcurvy-graſs with ſorrel; though Lewis ſays, it is far weaker than thoſe herbs, or than any mixture of the two.

MONEYERS, MONEYORS, or MONIERS, officers of the MINT, who work and coin gold and ſilver *money*; and anſwer all the waſte and changes.

MONEYERS is ſometimes alſo uſed for *bankers*; or thoſe who make a trade of turning and returning *money*.

MONGER, a little ſea-veſſel which fiſhermen uſe.

When a word ends with *monger*, it signifies *mercator*; from the Saxon *mangor*, i. e. *mercator*.

MONGOOSE, or MONGOOZ, in *Zoology*, is a species of LEMUR in the Linnæan system, the woolly *maucauco* of Pennant, and by some called the Macaffar fox. The sides of this animal are orange-coloured; its ears short and rounded; the end of the nose black; the eyes lodged in a circle of black, and the space between them of the same colour; the rest of the nose and sides of the cheek white; the whole upper part of the body covered with long, soft, thick fur, a little curled or waved, of a deep brownish ash-colour; the tail is long, covered with the same sort of hair, and of the same colour; the breast and belly white; the hands and feet naked and dusky; the nails flat, except that of the inner toe of the hind-feet; about the size of a cat; and varies, sometimes with white or yellow spots, and with a face wholly brown. It inhabits Madagascar and the adjacent isles; sleeps on trees, protects itself from rain, by turning its tail over its head, lives on fruits, and is very sportive and good-natured. Pennant. See *Tab.* III. *Quadrupeds*, N° 35.

MONITORY *letters*, are letters of warning and admonition, sent from an ecclesiastical judge upon information of scandals and abuses within the cognizance of his court.

MONK, anciently denoted a person who retired from the world to give himself up wholly to God, and to live in solitude and abstinence.

The word is derived from the Latin *monachus*, and that from the Greek *μονος*, *solitary*, of *μονη*, *sola*, *alone*; because the ancient *monks* lived in solitude, as the true *monks* still do.

Such were the HERMITS and ANACHORETS, who withdrew into deserts, and lived remote from all commerce of mankind.

Some writers, as father Helyot, Differt. Prelim. trace the origin of *monks* up as early as the time of the Therapeutæ; and maintain, that there had been an uninterrupted succession of *monks* from the Therapeutæ to St. Antony. Others, on the contrary, are contented with going back as far as St. Paul the Hermit.

The original of *monks* seems to have been this. The persecutions, which attended the first ages of the Gospel, forced some Christians to retire from the world, and live in deserts and places most private and unfrequented, in hopes of finding that peace and comfort among beasts, which were denied them among men. And this being the case of some very extraordinary persons, their example gave to much reputation to retirement, that the practice was continued, when the reason of its commencement ceased. After the empire became Christian, instances of this kind were numerous, and those, whose security had obliged them to live separately and apart, became afterwards united into societies. We may also add, that the mystic theology, which gained ground towards the close of the third century, contributed to produce the same effect, and to draw men into solitude for the purposes of enthusiastic devotion.

The *monks*, at least the ancient ones, were distinguished into *solitaires*, *cœnobites*, and *sarabaites*.

The *solitary* are those who live alone, in places remote from all towns and habitations of men, as do still some of the hermits.

The *cœnobites* are those who live in community with several others in the same house, and under the same superiors.

The *sarabaites* were strolling *monks*, having no fixed rule or residence.

The houses of *monks* again were of two kinds, viz. *monasteries*, and *lauræ*. See MONASTERY, and LAURA.

Those we call *monks* now-a-days, are cœnobites, who live together in a convent or monastery, who make vows of living according to a certain rule established by the founder, and wear a habit which distinguishes their order.

Those that are endowed, or have a fixed revenue, are most properly called *monks*, *monachi*; as the Charterux, Benedictines, Bernardines, &c. The Mendicants, or those that beg, as the Capuchins and Franciscans, are more properly called *religious*, and *friers*; though the names are frequently confounded.

The first *monks* were those of St. Antony; who, towards the close of the fourth century, formed them into a regular body, engaged them to live in society with each other, and prescribed to them fixed rules for the direction of their conduct. These regulations, which Antony had made in Egypt, were soon introduced into Palestine and Syria by his disciple Hilarion. Almost about the same time, Ammo or Eugenius, with their companions Gaddanas and Azyzas, instituted the monastic order in Mesopotamia, and the adjacent countries; and their example was followed with such rapid success, that, in a short time, the whole East was filled with a lazy set of mortals, who, abandoning all human connexions, advantages, pleasures, and concerns, were out a languishing and miserable life amidst the hardships of want, and various kinds of suffering, in order to arrive at a more close and rapturous communication with God and angels. From the East this gloomy institution passed into the West, and first into Italy, and its neighbouring islands; though it is uncertain who transplanted it thither. St. Martin, the celebrated bishop of Tours, erected the first monasteries in Gaul, and recommended this religious solitude with such power and efficacy, both by his instructions and his example, that his funeral is said to have been attended by no less than two thousand *monks*. From hence, the monastic discipline extended, gradually, its progress through the other provinces and countries of Europe. There were besides the *monks* of St. Basil, called in the East, *Cathari*, from *καθος πνευμα εχει την τροπον*, and those of St. Jerom, the hermits of St. Augustine, and afterwards those of St. Benedict and St. Bernard; at length came those of St. Francis and St. Dominic, with a legion of others; all which see under their proper heads, BENEDICTINES, &c.

Towards the close of the fifth century, the *monks*, who had formerly lived only for themselves in solitary retreats, and had never thought of assuming any rank among the facerdotal order, were now gradually distinguished from the populace, and endowed with such opulence and honourable privileges, that they found themselves in a condition to claim an eminent station among the supports and pillars of the Christian community. The fame of their piety and sanctity was so great, that bishops and presbyters were often chosen out of their order; and the passion of erecting edifices and convents, in which the *monks* and holy virgins might serve God, in the most commodious manner, was at this time carried beyond all bounds. However, their licentiousness, even in this century, was become a proverb; and they are said to have excited the most dreadful tumults and seditions in various places. The monastic orders were at first under the immediate jurisdiction of the bishops, from which they were exempted by the Roman pontiff, about the end of the seventh century; and the *monks*, in return, devoted themselves wholly to advance the interests, and to maintain the dignity of the bishop of Rome. This immunity which they obtained, was a fruitful source of licentiousness and disorder, and occasioned the greatest part of the vices, with which they were afterwards so justly charged. In the eighth century the monastic discipline was extremely relaxed both in the eastern and western provinces, and all efforts to restore it were ineffectual. Nevertheless, this kind of institution was in the highest esteem, and nothing could equal the veneration that was paid, about the close of the ninth century, to such as devoted themselves to the sacred gloom and indolence of a convent. This veneration induced several kings and emperors to call them to their courts, and to employ them in civil affairs of the greatest moment. Their reformation was attempted by Lewis the Meek, but the effect was of short duration. In the eleventh century they were exempted by the pope from the authority of their sovereigns, and new orders of *monks* were continually established; insomuch that in the council of Lateran, that was held in the year 1215, a decree was passed, by the advice of Innocent III. to prevent any new monastic institutions; and several were entirely suppressed. In the fifteenth and sixteenth centuries, it appears from the testimonies of the best writers, that the *monks* were generally lazy, illiterate, profligate, and licentious Epicureans, whose views in life were confined to opulence, idleness, and pleasure. However, the Reformation had a manifest influence in restraining their excesses, and rendering them more circumspect and cautious in their external conduct.

Monks are distinguished by the colour of their habits into *black*, *white*, *grey*, &c. Among the *monks*, some are called *monks of the choir*, others *professed monks*, and others *lay monks*; which last are destined for the service of the convent, and have neither clericate nor literature.

MONKS, *cloistered*, are those who actually reside in the house: in opposition to *extra-monks*, who have benefices depending on the monastery.

Monks are also distinguished into *reformed*, whom the civil and ecclesiastical authority have made matters of ancient convents, and put in their power to retrieve the ancient discipline, which had been relaxed; and *antient*, who remain in the convent, to live in it according to its establishment at the time when they made their vows, without obliging themselves to any new reform.

Anciently, the *monks* were all lay-men, and were only distinguished from the rest of the people by a particular habit, and an extraordinary devotion. Not only the

monks were prohibited the priesthood, but even priests were expressly prohibited from becoming *monks*, as appears from the letters of St. Gregory. Pope Syricius was the first who called them to the clericate, on occasion of some great scarcity of priests, that the church was then supposed to labour under: and since that time, the priesthood has been usually united to the monastical profession.

MONKS, *professed*. See PROFESSED.

MONKS, *proprietary*. See PROPRIETARY.

MONK-*fish*, the English name of a species of the squalus, according to the new Artedian system; called *rhina* and *squatina* by the old authors. It is distinguished by Artedi from the other squali, by the name of the *squalus* with no *pinna ani*, and with the mouth on the top of the head: it is of a middle shape, between the long and flat cartilaginous fishes, being much broader than the galei, and rounder than the rays; it grows to a very large size, sometimes to four, five, or six feet long; it is covered all over with a mucous substance, but under it the skin is harsh, and rough enough to serve for the polishing wood and ivory; it is of a brownish grey on the back and sides, and white under the belly; the head is flatted and roundish, and the mouth large, and opening at the extremity of the snout, not, as in other of the fishes of this class, under the head; it has three rows of teeth, eighteen in a row; its eyes are large, and placed near its mouth, and seem as if meant for looking sideway, rather than up or down; its upper pair of fins very much resemble wings, from whence it has its name of the *angel-fish*, and at the extremities of these are a number of sharp hooked thorns; it has also a row of short prickles on its back. See *Tab.* III. *of Fish*, N° 27.

It is common in the English seas, and is not unfrequently caught in Cornwall.

MONK's *hood*, a name given to several species of ACONITE, or WOLF's-*bane*.

The flowers of this plant are in common use in the country, to garnish dishes, though generally suspected of being poisonous; but the stalks have been found very violently so, according to an account given in the Philosophical Transactions. Phil. Trans. N° 432.

The young shoots of this plant have some resemblance to celery, and were put into the sallad as such.

MONK's *rhubarb*. See RHUBARB, and DOCK.

MONKS *frow*, among *Sailors*, is when the selvedges of sails are laid a little over one another, and sewed on both sides.

MONKEY, in *Zoology*, a name given by way of distinction to those apes which have tails; the others, or those without tales, being more properly called *apes*.

The same distinction holds in Latin, the tailed ones being called *cercopitheci*, and those without tails *simiæ*. See CERCOPITHECUS and SIMIA.

Mr. Pennant distributes *monkies* into two classes, viz. 1. Those of the old world, or the continents of Asia and Africa, having within each lower jaw pouches for the reception of their food, buttocks generally naked, and tails strait, but not prehensile. Under this class he enumerates and describes the dog-faced *monkey*, or *simia hamadryas*, of Linnæus; the lion-tailed *monkey*, or *simia sylvanus*, of which there are several varieties; for one of which see *Tab.* III. *Quadrupeds*, *fig.* 36. the hair-lipped *monkey*, or *simia labiata*; the spotted *monkey*, or *simia diana*; the green *monkey*, CALLITRICHUS, or *simia sabæa*; the white-eye-lid *monkey*, or *simia œthiops*; the mustache *monkey*, or *simia cephus*; the talapoin of Buffon; the negro *monkey*; the ascot, or *simia agilis*; the red *monkey*; the Chinese; the varied *monkey*; the *monkey* of Cochin-China; the tawny; the winking; the goat; the annulated *monkies*; and the Philippine, or *simia fascicularis* of Linnæus. 2. *Monkies* of the new world, or the continent of America, having neither pouches in their jaws, nor naked buttocks: the tails of many are prehensile and naked on the under side, for a certain space next their end: of those with prehensile tails, he enumerates the preacher, GUARIBA, or *simia Beelzebub*, of Linnæus; the four-fingered *monkey*, or *simia paniscus*; the capuchin, or *simia capucina*, and *trepida*, and *apella*; the weeper; the orange *monkey*, or *simia sciurea*; the horned *monkey*, or *simia fatuellus*; and the Antigua *monkey*: of those with strait tails, not prehensile, he reckons the fox-tailed, or *simia pithecia* of Linnæus; the great-eared or *simia Midas*; the striated, or *simia fascicus*; the silky, or *simia rufiventer*; the red-tailed, or *simia ursina*; and the fair *monkey*. See Pennant's Synopsis of Quadrupeds, p. 107, 134.

MONKEY of the West Indies. See GUARIBA.

MONKEY, *green*. See CALLITRICHUS.

MONKEY, *in the Sea Language*, a block made of iron, with a catch, used in guns for driving piles.

MONNIERIA, in *Botany*, a genus of the *diadelphia pentandria* class: the characters are, that the calyx is divided into five segments, and the corolla ringent; the fruit is formed into five capsules, containing single seeds. There is only one species.

MONOCEROS, *Unicorn*, in *Astronomy*, a southern constellation formed by Hevelius, containing in his catalogue nineteen stars, and in the Britannic Catalogue thirty-one: the situation, longitude, latitude, &c. are as follow.

Names and situations of the stars.	Mag.	Longitud.		Latitude.		
		°	′	°	′	″

MONOCEROS *minor*, in *Ichthyography*, the name of a fish caught in the American seas; its usual length is a foot and half; its height about nine inches, very flat bodied, and high backed like a perch, and bow-bellied; its head has some resemblance to that of a baboon.

From the top of the head is prolonged a smooth, round, tapered strait horn, two inches round about the root, and about three inches long; this seems to have no bone within it, nor is inserted into any, but seems merely the cuticle hardened, into a sort of horny substance; the back-fin reaches from the head to the tail; it is covered with a tough thick skin, feeling somewhat rough.

MONOCEROS *piscis*, is also used as the name of a fish, common in the American seas; and called *pira oca* by Margrave, and some other authors; and by the Portuguese *picus porcus*.

It is a very small fish, of about three fingers breadth long, and two broad where broadest; it is of a flatted compressed shape; the mouth is very small, but of the figure of that of a hog; a little behind the eyes, on the ridge of the back, it has an upright horn, a little bending backwards, less than a finger's breadth long, of a rounded figure, and of the thickness of a large thread; its skin is very rough to the touch, and is of an obscure yellowish colour. The fins and the ridge at the back are yellower than any other part of it. See *Tab.* III. *of fishes*, N° 28.

MONOCHORD, a musical instrument wherewith to try the variety and proportion of musical sounds.

The *monochord*, according to Boethius, is an instrument invented by Pythagoras, for measuring geometrically, or by lines, the quantities and proportions of sounds.

The ancient *monochord* was composed of a rule divided and subdivided into divers parts, whereon there was a string pretty well stretched upon two bridges, at each extreme thereof. In the middle between both was a moveable bridge, called *magas*, by means of which, in applying it to the different divisions of the line, the sounds were found to be in the same proportion to one another, as the divisions of the line cut by the bridge were.

The *monochord* is also called the *harmonical canon*, or *canonical rules*; because serving to measure the degrees of gravity, and acuteness of sounds. Ptolemy examines his harmonical intervals by the *monochord*.

There are alſo *monochords* with divers ſtrings, and a multitude of fixed bridges; but the uſe of all theſe may be ſupplied by one ſingle moveable bridge; by only ſhifting it under a new chord or ſtring, which is placed in the middle, and repreſents the entire ſound, or open note, anſwering to all the diviſions on the other bridges.

When the chord was divided into equal parts, ſo that the terms were as 1 and 1, they called them *uniſons*; if they were as 2 to 1, *octaves*, or *diapaſons*; when they were as 8 to 7, *ſtibs*, or *diapentes*; if they were as 4 to 3, they called them *fourths*, or *diateſſarons*; if the terms were as 5 to 4, *dytons*, or a *greater third*; if as 6 to 5, a *demi-dyton*, or a *leſſer third*; laſtly, if as 24 to 25, *demi-ditons* or *diaſes*.

The *monochord*, being thus divided, was properly what they call a *ſyſtem*, of which there were many kinds, according to the different diviſions of the *monochord*.

Dr. Wallis has taught the diviſion of the *monochord* in the Philoſophical Tranſactions; but that inſtrument is now diſuſed, the modern muſic not requiring ſuch diviſion.

MONOCHORD, Μονόχορδον, formed of μόνος, *ſolus*, *ſingle*, and χορδὴ, *chord*, is alſo uſed for any muſical inſtrument, conſiſting of only one chord or ſtring. Such is the trumpet-marine.

MONOCHROMA, Μονόχρωμα, compounded of μόνος, *ſingle*; and χρῶμα, *colour*, a picture all of one colour.

MONOCOLI, Μονόκωλοι, a kind of fabulous men, who, as the Arabians give out, inhabit the country of Segir, in Arabia Felix; and are but half formed.

The word is Greek, compounded of μόνος, *one*, and κῶλον, *a member*.

MONOCULUS, in *Zoology*, the name of a genus of inſects, of the PODARIA kind, and of the order of *aptera*, in the Linnæan ſyſtem.

Its body is ſhort, of a roundiſh figure, and covered with a firm cruſtaceous ſkin; the fore-legs are ramoſe, and ſerve for leaping and ſwimming; it has but one eye, which is large, and compoſed of three ſmaller ones.

Of this genus, many of which have been reckoned among the microſcopic animals, authors enumerate a great number of ſpecies. Linnæus enumerates nine ſpecies.

MONODON, in the Linnæan ſyſtem of *Zoology*, the name of the monoceros, or ſea unicorn, a fiſh of the whale-kind, which makes a diſtinct genus of fiſhes; the characters of which are, that it has a pipe in the forehead, and no fin on the back, and two very long ſpiral teeth in its upper jaw.

The word is Greek, compounded of μόνος, *one*, and ὀδοὺς, *a tooth*, and expreſſes this fiſh's having only a ſingle tooth, referring to its ſpiral horn.

Artedi makes the *monodon* a peculiar genus among the cetaceous fiſhes, or plagiuri. The NARWAL is the only known ſpecies of this genus.

MONODY, Μονῳδία, compounded of μόνος, *ſolus*, and ᾠδὴ, *ſong*, in the *Ancient Poetry*, a kind of mournful ſong, or ditty, ſung by a perſon all alone, to utter his grief.

MONOECIA, in *Botany*, the twenty-firſt claſs of plants which have not the male and female parts, that is, the ſtamina and piſtillum in the ſame, but in different flowers; and thoſe on the ſame individual, or on the different ſtalks, growing from the ſame root; thoſe which contain the ſtamina, are called the male flowers, thoſe which contain the piſtillum, the female ones. See *Tab.* I. *of Botany*, *claſs* 21.

The word is derived from the Greek μόνος, the ſame, and οἶκος, *habitation*.

The orders of this claſs are eleven, viz. 1. *Monandria*, comprehending ſuch plants as have their male flowers furniſhed with one ſtamen; to which belong five genera, *zannichellia*, *ceratocarpus*, *cynomorium*, *elaterium*, and *chara*. 2. *Diandria*, with two ſtamina, containing two genera, *lemna* and *anguria*. 3. *Triandria*, with three ſtamina, including twelve genera; *amphalea*, *typha*, *ſparganium*, *carex*, *oxis*, *triſpicum*, *elyna*, *cacao*, *avena*, *triticum*, *bromus*, and *phyllanthus*. 4. *Tetrandria*, with four ſtamina; comprehending eight genera, *centella*, *batula*, *betula*, *urtica*, *morus*, *cicca*, *ſcrpicula*, and *littorella*. 5. *Pentandria*, with five ſtamina, containing eight genera; *xanthium*, *ambroſia*, *parthenium*, *iva*, *iuca*, *amaranthus*, *nephelium*, and *clibadium*. 6. *Hexandria*, with ſix ſtamina, to which belong two genera; *zizania* and *phorus*. 7. *Heptandria* with ſeven ſtamina, of which there is one genus, viz. *guettarda*. 8. *Polyandria*, with many ſtamina, including thirteen genera, viz. *ceratophyllum*, *myriophyllum*, *ſagittaria*, *hydnora*, *theligonum*, *viburnum*, *quercus*, *juglans*, *fagus*, *corylus*, *carpinus*, *platanus*, and *liquidambar*. 9. *Monadelphia*, with one ſet of united ſtamina, containing fifteen genera, viz. *buxus*, *pinus*, *cupreſſus*, *thuja*, *acalypha*, *dalechampia*, *phyllanthus*, *cupania*, *croton*, *ricinus*, *jatropha*, *ſterculia*, *hippomane*, *ſtillingia*, and *guerina*. 10. *Syngeneſia*, with the anthers of the ſtamina united, including ſix genera, viz. *trichoſanthes*, *momordica*, *cucumis*, *cucurbita*, *feroa* and *bryonia*. 11. *Gynandria* with the male flowers furniſhed with ſtamina, that grow out of a kind of ſtyle or imperfect piſtillum, the perfect one being in the female flower; containing two genera, viz. *andrachne*, and *agynoia*. See *Tab.* VI. *Botany*, *claſs* 21.

MONOGAMY, compounded of μόνος, *ſolus*, and γάμος, *marriage*, the ſtate or condition of thoſe who have only married once, or are reſtrained to a ſingle wife. See POLYGAMY.

MONOGASTRIC, in *Anatomy*, a name given by Vieuſſens, and ſome of the French writers, to one of the muſcles of the ear, called by Cowper, the *internus auris*, and more properly by Albinus, the *tenſor tympani*.

MONOGRAM, Μονόγραμμος, a cipher, or character, compoſed of one or more letters interwoven; being a kind of abbreviation of a name; anciently much uſed as a badge, ſeal, arms, &c.

Under the eaſtern empire, it is uſual to find MIK, which are the *monogram* of Maria, Jeſus, Conſtantine.

The uſe of *monograms* is of an ancient ſtanding, as appears from Plutarch, and from ſome Greek medals of the time of Philip of Macedon, Alexander his ſon, &c.

The Roman LABARUM bore the *monogram* of Jeſus Chriſt, conſiſting of two letters, a P placed perpendicularly through the middle of a X, i. e. gr. ☧, as we find it in ſeveral medals of the time of Conſtantine, thoſe being the two firſt letters of the word Χριστὸς, *Chriſt*.

Kings formerly marked their coins with their *monograms*: of this we have inſtances in Charlemagne's coins. That prince alſo uſed the *monogram* for his ſignature. Eginhard gives us this reaſon for it, viz. that Charlemagne could not write; and that, having attempted in vain to learn in his grown age, he was reduced to the neceſſity of ſigning with a *monogram*.

The ancients alſo uſed *monograms* as notes, or abbreviations of inſcriptions; for the underſtanding whereof we have expreſs treatiſes of Valerius Probus, Sert. Uffatius, &c.

MONOGRAPHI, in *Botany*, authors who have written expreſs treatiſes on only one plant; as Douglas on the Gueruſey filx, &c.

MONOLOGUE, formed of μόνος, *ſolus*; and λόγος, *diſcourſe*, *ſpeech*, a dramatic ſcene, wherein a perſon appears alone on the ſtage, and ſpeaks to himſelf. See SOLILOQUY.

MONOMACHIA, Μονομαχία, from μόνος, *ſolus*, and μάχη, *combat*, a duel, or ſingle combat of man againſt man.

Monomachia was anciently allowed by law, for the trial or proof of crimes. It was even permitted in pecuniary cauſes, as appears by ancient records. It is now forbid both by the civil and canon laws. See COMBAT.

Alciat has written a treatiſe *De Monomachia*.

MONOMACHON, a name given by ſome to the inteſtine otherwiſe called COECUM.

MONOMERES, a word uſed by the ancients alone, but more frequently joined with the word *phorbeia*, to expreſs one ſort of the bandage uſed to confine the breath, by thoſe who played on the ancient pipe. This conſiſted only of one ſtrait, and one tranſverſe piece; and the latter came fully over the mouth, and cloſed it up, except that a hole was cut in it to receive the mouth-piece of the pipe. The *phorbeiæ* conſiſted of ſeveral pieces, and only tied up the lower-lip.

MONOMIAL, in *Algebra*, a root or quantity that has but one name; or conſiſts but of one part or member. Such are *a*, *ab*, *aabb*. See QUANTITY, BINOMIAL, TRINOMIAL, ROOT, &c.

Monomials may be either RATIONAL, or irrational.

MONOPAGIA, a word uſed by ſome medical writers, for that ſpecies of head-ach which affects only one point, or ſmall part of the head.

MONOPETALOUS, in *Botany*, a term applied to flowers which have only one petalum, or leaf. See theſe flowers repreſented in *Tab.* VIII. *of Botany*, *claſs* 1. 2. 3. 4. and *Tab.* X. *claſs* 20.

MONOPHAGI, Μονοφάγοι, in *Antiquity*, a deſignation given to thoſe who celebrated the Æginean feſtival, becauſe they feaſted or eat together without the aſſiſtance of their ſervants; none but the denizens of that iſland being allowed to be preſent.

MONOPHYSITES, from μόνος, *ſolus*, and φύσις, *nature*, a general name given to all thoſe ſectaries in the Levant, who only own one nature in Jeſus Chriſt; and maintain, that the divine and human nature of Chriſt were ſo united, as to form only one nature, yet without any change, confuſion, or mixture of the two natures.

The *Monophyſites*, however, properly ſo called, are the followers of Severus, a learned monk of Paleſtine, who was created patriarch of Antioch, in 513, and Petrus Fullenſis.

The *Monophyſites* were encouraged by the emperor Anaſta-

ſius,

sius, but depressed by Justin and succeeding emperors. However this sect was restored by Jacob Baradæus, an obscure monk, insomuch, that when he died bishop of Edessa, A. D. 588, he left it in a most flourishing state in Syria, Mesopotamia, Armenia, Egypt, Nubia, Abyssinia, and other countries. The laborious efforts of Jacob were seconded in Egypt, and the adjacent countries, by Theodosius, bishop of Alexandria, and he became so famous that all the *Monophysites* of the East considered him as their second parent and founder, and are to this day called JACOBITES, in honour of their new chief. The *Monophysites* are divided into two sects or parties, the one African, the other Asiatic; at the head of the latter is the patriarch of Antioch, who resides for the most part in the monastery of St. Ananias, near the city of Merdin: the former are under the jurisdiction of the patriarch of Alexandria, who generally resides at Grand Cairo, and are subdivided into COPHTS and ABYSSINIANS. From the fifteenth century downwards, all the patriarchs of the *Monophysites* have taken the name of Ignatius, in order to shew that they are the lineal successors of Ignatius, who was bishop of Antioch in the first century, and consequently the lawful patriarchs of Antioch. In the seventeenth century, a small body of the *Monophysites* in Asia, abandoned, for some time, the doctrine and institutions of their ancestors, and embraced the communion of Rome; but the African *Monophysites*, notwithstanding that poverty and ignorance which exposed them to the seductions of sophistry and gain, stood firm in their principles, and made an obstinate resistance to the promises, presents, and attempts employed by the papal missionaries, to bring them under the Roman yoke: and in the eighteenth century, those of Asia and Africa have persisted in their refusal to enter into the communion of the Romish church, notwithstanding the earnest intreaties and alluring offers, that have been made from time to time by the pope's legates, to conquer their inflexible constancy. The *Monophysites* propagate their doctrine in Asia with zeal and affluity, and have not long ago gained over to their communion a part of the Nestorians, who inhabit the maritime coasts of India.

MONOPODIA, among the *Ancients*, a sort of tables used in their feasts, and distinguished by this name from their having but one foot; the name being derived from the Greek, μονος, *one*, and ποδ, *foot*.

MONOPOLY, MONOPOLIUM, formed of μονος, *solus*, and πωλεω, *vendo*, q. d. *I sell alone*, an unlawful kind of traffic, when one or more persons make themselves sole masters of any commodity, trade, manufacture, or the like, with design to enhance its price; those who have occasion for it being obliged to purchase it at their hands, and on their own terms.

There are two kinds of *monopolies*: the one, when a merchant buys up, for instance, all the corn of a province, to retail it at an advanced rate to the people. The other, when a letter, or PATENT, is procured from the prince, prohibiting any other person to sell a particular commodity besides the patentee.

Monopolies are much the same offence in other branches of trade, that ENGROSSING is in provisions. These had been carried to an enormous height during the reign of queen Elizabeth; but were in great measure remedied by stat. 21 Jac. I. cap. 3. which declares such *monopolies* to be contrary to law, and void (except as to patents, not exceeding the grant of fourteen years, to the authors of new inventions); and *monopolists* are punished with the forfeiture of treble damages, and double costs, to those whom they attempt to disturb; and if they procure any action, brought against them for these damages, to be stayed by any extrajudicial order, other than that of the court wherein it is brought, they incur the penalties of PRÆMUNIRE.

MONOPS, in *Natural History*, a name given by Ælian, and some other of the old Greek writers, to the ROMAUSA. The name *monopus* was given this animal, according to Aristotle, by the people of the country where the creature was most frequent, and therefore is not to be attempted on any Greek etymology. Some of the Greeks have called the same creature *monopus*, and some *ballinthos*.

MONOPTERE, μονοπτερος, a kind of temple among the ancients, round, and without walls; having its dome supported by columns.

MONOPTOTE, MONOPTOTON, in *Grammar*, a noun which has only one case; as *inficias*.

MONOPYRENEOUS *fruits*, are such as only contain one kernel or seed.

MONORCHIS. Beside the common signification of this word as the name of a plant, physicians have also used it to express a man who has but one testicle.

MONORHYME, from μονος, *solus*, and ῥυθμος, *rhyme*, a poetical composition, all the verses whereof end with the same rhyme.

Monorhymes are said to have been invented by the old French poet Leonin, who addressed some Latin verses of this kind to pope Alexander III. whence they are also called *Leonine verses*.

MONOSPERMALTHÆA, in *Botany*, a name given by Mr. Hinard, in the Acta Germanica, to a genus of plants afterwards called WALTHERIA by Linnæus.

MONOSTICH, MONOSTICHON, an epigram, or poetical piece, consisting of one single verse.

MONOSYLLABLE, MONOSYLLABUM, a word of a single syllable; or, that consists of one or more letters which are pronounced together.

The French language abounds in *monosyllables* more than any other. This renders it the more perplexing to foreigners, and yet the beauty of the language seems to consist in it. One of the best and smoothest lines in Malherbe consists of twelve *monosyllables*: speaking of Calista, he says, *—Et moi je ne vai rien quand je ne la vis pas*. In this the genius of the English tongue differs very much from the French, an uninterrupted series of *monosyllables* in the former having always an ill effect. This Mr. Pope both intimates and exemplifies in the same verse. *Awaken low words oft creep in one dull line*. Pasquier cites an Elegy of forty-two verses, consisting wholly of *monosyllables*.

MONOTHELITES, compounded of μονος, *single*, and θελημα, *will*, of θελω, *volo*, *I will*, an ancient sect, which sprung out of the EUTYCHIANS; thus called, as only allowing of one will in Jesus Christ.

The opinion of the *Monothelites* had its rise in 630, and had the emperor Heraclius for an adherent: it was the same with that of the Acephalous Severians.

They allowed of two wills in Christ, considered with regard to the two natures; but reduced them to one, by reason of the union of the two natures; thinking it absurd there should be two free wills in one and the same person. See ECTHESIS and TYPE.

They were condemned by the fifth general council, in 680, as being supposed to destroy the perfection of the humanity of Jesus Christ, depriving it of will and operation. Their sentiments were afterwards embraced by the MARONITES.

MONOTONIA, MONOTONY, a want of variation, or inflexion, of the voice; or a fault in pronunciation, where long series of words are delivering with one unvaried tone. This is one of the principal faults of our English orators. *Monotonia* is opposed to chanting or singing in speaking.

MONOTRIGLYPH, in *Architecture*, denotes the space of one TRIGLYPH, between two pilasters or two columns.

MONOTROPA, in *Botany*, the name of a genus of plants, of the *decandria monogynia* class; its characters are, that it has no empalement, and ten petals, the outer five of which are hollowed at their base, and yield a sweet juice; the fruit is a capsule with five valves. There are two species. This is called Fournefort, *orobanche alba*, and by Dillenius, *hypopitis*.

MONRINGION, in *Botany*, a name given by some authors to the tree whose fruit is the ben-nut, and whose wood is the *lignum nephriticum* of the shops.

MONS *lunæ*. See ADDUCTOR.

MONSEIGNEUR, compounded of *mon*, *my*, and *seigneur*, *lord*, in the plural MESSEIGNEURS, a title of honour and respect used by the French in writing to persons of superior rank, or quality.

Dukes, peers, archbishops, bishops, and presidents *à la mortier*, are complimented with the title of *monseigneur*. In the petitions presented to the sovereign courts, they use the term *messeigneurs*.

MONSEIGNEUR, absolutely used, is a title now restrained to the dauphin of France.

This custom was unknown till the times of Louis XIV. till then, the dauphin was styled *monsieur le dauphin*.

MONSIEUR, a compound of *mon*, *my*, and *sieur*, *sir*, in the plural MESSIEURS, a term or title of civility, used by the French, in speaking to their equals, or those a little below them; answering to Mr. or Sir, among the English.

The superscriptions of all letters begin, *A monsieur monsieur* such a one.

The use of the word *monsieur* was formerly more extensive than at present: they applied it to people who lived many ages before them. Thus, *monsieur* St. Augustine, *monsieur* St. Ambrose; and the vulgar still say, *monsieur* St. Paul, *monsieur* St. Jaques, &c. The Romans, during the flourishing time of their liberty, were unacquainted with that term of parade and flattery, which they afterwards made use of in the word *dominus*. In speaking or writing to each other, they only gave each other their proper names; which practice lasted even after Cæsar had brought the republic under his command: but after the Roman emperors were once well seated in the throne, the courtiers and minions, who by flattery sought to procure

cure favours from them, studied new honours. Suetonius observes, that a comedian on the theatre having called Augustus *dominus*, *lord*; the spectators all flared at him: so that the emperor forbad, for the future, the title to be attributed to him. Caligula was the first who expressly commanded himself to be called *dominus*. Martial, entirely devoted to tyranny, calls Domitian, *dominum ac deum nostrum*. In time, the title was also applied to the people; and of *dominus*, at length was formed DON.

MONSIEUR, absolutely used, is a title or quality appropriated to the second son of France, or the King's brother. In a letter of Philip De Valois, that prince, speaking of his predecessor, calls him *monsieur le roy, monsieur the king*. At present nobody calls the king *monsieur*, but the children of France. See SIRE.

MONSONIA, in *Botany*, a genus of the *pentadelphia decandria* class: its characters are, that it has a five-leaved calyx; the corolla has five petals; the stamina are fifteen, and united in five filaments; the style is divided into five segments, and the fruit is a five-berried capsule. There is only one species.

MONSOON, a regular or periodical wind, in the East Indies, blowing constantly the same way, during six months of the year, and the contrary way the remaining six.

In the Indian ocean, the winds are partly *general*, and blow all the year round the same way, as in the Ethiopic ocean; and partly *periodical*, i. e. half the year blow one way, and the other half near on the opposite points: and those points and times of shifting differ in different parts of this ocean. These latter are what we call *monsoons*.

The shifting of these *monsoons* is not all at once: and in some places the time of the change is attended with calms, in others with variable winds; and particularly those of China, at ceasing to be westerly, are very subject to be tempestuous: and such is their violence, that they seem to be of the nature of the West India HURRICANES, and render the navigation of those seas very unsafe at that time of the year. These tempests the seamen call the *breaking up of the monsoon*.

Monsoons, then, are a species of what we otherwise call TRADE-*winds*.

They take the denomination *monsoon* from an ancient pilot, who first crossed the Indian sea by means hereof. Though others derive the name from a Portuguese word signifying *season*, or change of wind, and *sea*.

Lucretius and Apollonius make mention of annual winds which arise every year, *certis flabris*, which seem to be the same with what in the East Indies we now call *monsoons*. For the physical cause of these winds, see WIND.

MONSTER, MONSTRUM, a birth or production of a living thing, degenerating from the proper and usual disposition of parts, in the species it belongs to. As, when there are too many members, or too few; or some of them are extravagantly out of proportion, either on the side of defect or excess.

The word comes from the Latin, *monstrum*, of *monstrando, showing*. Whence also the box wherein relics were anciently kept to be shewn was called *monstrum*. Dugdale mentions an inventory of the church of York with this article, *Item unum monstrum cum ossibus sancti Petri in Beryl, & crucifixo in summitate*.

Aristotle defines a *monster* to be a defect of nature, when, acting towards some end, it cannot attain to it, by reason some of its principles are corrupted.

Monsters do not propagate their kind; for which reason some rank mules among the number of *monsters*, as also hermaphrodites.

Females, which naturally bring forth twins, are found most liable to produce *monsters*. The reason, probably, is owing to this; that though the twins are covered with one common chorion, yet they have each their separate amnios, which, by their contiguity, may chance to grow together, and so occasion a confusion or blending of the parts. Hence so many double creatures.

F. Malebranche accounts for the production of *monsters*, in the animal world, thus. The Creator has established such a communication between the several parts of his creation, that we are not only naturally led to imitate one another, i. e. have a disposition to do the same things, and assume the same manners, with those with whom we converse; but we also have certain natural dispositions, which incline us to compassion, as well as imitation. These things most men feel, and are sensible of; and, therefore, they need not be proved. The animal spirits then are not only naturally carried into the respective parts of the body to perform the same actions, and the same motions, which we see others do, but also to receive in some manner their wounds, and take part in their sufferings.

Experience tells us, that, when we look attentively on any person severely beaten, or that has a large wound, ulcer, or the like, the spirits immediately flow into those parts of our body which answer to those we see suffer in the other; unless their course be stopped from some other principle. This flux of spirits is very sensible in persons of a delicate constitution, who frequently shudder, and find a kind of trembling in the body, on these occasions; and this sympathy in bodies produces compassion in the mind.

Now, it must be observed, that the view of a wound, &c. wounds the person who views it the more strongly and sensibly, as the person is more weak and delicate; the spirits making a stronger impression on the fibres of a delicate body than on those of a robust one. Thus strong vigorous men, &c. see an execution without much concern, while women, &c. are struck with pity and horror. As to children still in their mothers womb, the fibres of their flesh being incomparably finer than those in women, the course of the animal spirits must necessarily produce much greater alterations in them.

These things being laid down, *monsters* are easily accounted for. Suppose, v. gr. a child born a fool, and with all its legs and arms broken in the same manner as those of criminals in some countries are; which case we choose to instance in, because we are told from Paris, that such a *monster* was actually born there, and lived in one of their hospitals twenty years: the cause of this accident, according to the principles laid down, was, that the mother being a criminal executed, every stroke given to the poor man struck forcibly the imagination of the woman; and, by a kind of counter-stroke, on the tender and delicate brain of the child. Now though the fibres of the woman's brain were strongly shaken by the violent flux of animal spirits on this occasion; yet they had strength and consistence enough to prevent an entire disorder; whereas the fibres of the child's brain, being unable to bear the shock of those spirits, were quite ruined; and the ravage was great enough to deprive him of reason all his life-time.

Again, the view of the execution frighting the woman, the violent course of the animal spirits was directed forcibly from the brain to all those parts of the body corresponding to the suffering parts of the criminal; and the same thing must also happen in the child. But in regard the bones of the mother were strong enough to resist the impulse of those spirits, they were not damaged; and yet the rapid course of these spirits could easily overpower and break the tender and delicate fibres of the bones of the child; the bones being the last parts of the body that are formed, and having a very tender consistence while the child is yet in the womb.

To which it may be here added, that had the mother determined the course of these spirits towards some other parts of her body, by tickling or scratching herself vehemently, the child would not, in all probability, have had his bones broken; but the part answering that, to which the motions of the spirits was determined, would have been the sufferer.

Hence appears the reason why women, in the time of gestation, seeing person, &c. marked in such a manner in the face, imprefs the same mark on the same parts of the child; and why, upon rubbing those hidden parts of the body, when startled at the sight of any thing, or agitated with any extraordinary passion, the mark of impression is fixed on that hidden part rather than on the face of the child. From the principles here laid down, if the reader is disposed to allow them, may most, if not all, the phenomena of *monsters* be easily accounted for.

The French Academicians have of late disputed whether *monsters*, that is, creatures born with their organs preternaturally formed or situated, supernumerary or defective, were originally so formed in their first stamina; or whether this deformity has been owing to some accidental change upon them. The arguments for these opinions, are remarks upon particular histories of such *monsters*, which we cannot abridge, and therefore must refer to the Memoirs de l'Acad. des Sciences, 1733, 1734, 1734, 1739.

A MONSTER, in *Law*, is one that hath not human shape, and yet is born in lawful wedlock; and such may not purchase or retain lands; but a person may be an heir to an ancestor's land, though he have some deformity in any part of his body. If there appears no other heir than such a prodigious birth, the land shall escheat to the lord.

MONSTERS, *vegetable*. There are also monstrous productions in the vegetable world: such, e. gr. are what some botanists call MULES.

Florists also give the denomination *monsters*, or *monstrous flowers*, to those flowers which are not only double, but double podded; or when, instead of one flower, there are two or three rising one above another from a single stalk.

MONSTRANS *de droit*, a writ iſſuing out of chancery, for reſtoring a perſon to lands or tenements that are his in right, though on ſome occaſion found in poſſeſſion of another lately dead.

MONSTRAVERUNT, a writ which lies for a tenant who holds by free charter in ancient demeſne, upon his being diſtrained for the payment of any ſervice or impoſition contrary to the liberty he does or ought to enjoy.

MONTANISTS, ancient heretics, ſo called from their leader Montanus, who acted the prophet, and had his propheteſſes.

Montanus was an obſcure man, without any capacity or ſtrength of judgment, who lived in a Phrygian village, called Pepuza, towards the cloſe of the ſecond century. This weak man gave out that he was the *paraclete*, or comforter, which the divine Saviour, at his departure from the earth, promiſed to ſend to his diſciples to lead them to all truth. Some have aſſerted, that *Montanus* pretended to be the Holy Ghoſt. But others have obſerved, with greater reaſon, that he made a diſtinction between the *paraclete*, promiſed by Chriſt to his apoſtles, and the holy ſpirit: underſtanding by the former a divine teacher, who was to perfect the Goſpel by the addition of ſome doctrines omitted by our Saviour, and to caſt a full light on others which were expreſſed in an obſcure and imperfect manner: accordingly he pretended to be this divine teacher. Under this character, he added to the laws of the Goſpel many auſtere deciſions; inculcated the neceſſity of multiplying faſts; prohibited ſecond marriages as unlawful; maintained that the church ſhould refuſe abſolution to thoſe who had fallen into the commiſſion of enormous ſins; and condemned all care of the body, eſpecially all neatly in dreſs, and all female ornaments. He ſhewed the ſame averſion to the nobleſt employments of the mind, that he did to the innocent enjoyments of life; and gave it as his opinion, that philoſophy, arts, and whatever favoured of polite literature, ſhould be mercileſſly baniſhed from the Chriſtian church. He looked upon thoſe Chriſtians as guilty of a moſt heinous tranſgreſſion, who ſaved their lives, by flight, from the perſecuting ſword, or who ranſomed them by money, from the hands of their cruel and mercenary judges. He added many other precepts equal to theſe in ſeverity and rigour: and iſſued many predictions concerning the diſaſters that were to happen in the empire, and the approaching deſtruction of the Roman republic, which rendered him obnoxious to the governing powers. *Montanus* was, therefore, firſt by a decree of certain aſſemblies, and afterwards by the unanimous voice of the whole church, ſolemnly ſeparated from the body of the faithful. However he had many patrons and adherents, the principal of whom was Tertullian, and his cauſe ſpread abroad through Aſia, Africa, and a part of Europe. Moth. Eccl. Hiſt. vol. i. p. 192, &c. 8vo.

The *Montaniſts* are the ſame with what were otherwiſe denominated *Phrygians*, *Cataphrygians*, and *Quintilians*; which ſee.

MONTANUM *ſaxum*. See VERU.

MONTENSES. See AGONISTICI, CAMPITÆ, and DONATISTÆ.

MONTH, in the *Computation of Time*, the twelfth part of the year.

Among the ancient Greeks, the year was divided into twelve *months*, which contained thirty and twenty-nine days alternately; but ſo as the *months* of thirty days always went before thoſe of twenty-nine; the former were termed πλήρεις, *full*, and ἔμπλεοι, as ending on the tenth day; the latter were called κοῖλοι, *hollow*, and from their ending on the ninth day, ἐννεάφθοι.

In order to underſtand their method of reckoning the days of the *month*, it muſt be conſidered that every *month* was divided into three δεκάδες or three decads of days; the firſt decad they called the πρώτη ἀρχομένου or ἱσταμένου; the ſecond, δευτέρα μεσούντος; the third, τρίτη φθίνοντος, or ἑνὸς καὶ νέας. Whence the firſt day of the *month* was called ἱσταμένου, as falling upon the new moon, and πρώτη ἀρχομένου or ἱσταμένου, as being the firſt day of the firſt decad; the ſecond day was termed, δευτέρα ἱσταμένου; the third, τρίτη ἱσταμένου; and ſo on to the tenth inclusive.

The firſt day of the ſecond decad, which was the eleventh day of the *month*, was called πρώτη μεσούντος or πρώτη φθίνοντος; the ſecond of this decad, δευτέρα μεσούντος, or φθίνοντος, and ſoon to δεκάτη, the twentieth, which was the laſt of the ſecond decad.

The firſt day of the third decad was termed πρώτη τοῦ μηνὸς; the ſecond, δευτέρα τοῦ μηνὸς, and ſo of the reſt. Sometimes they inverted the numbers of this laſt decad, the firſt being called ἑνδεκάτη φθίνοντος; the ſecond, δωδεκάτη φθίνοντος; the third, τρισκαιδεκάτη; and ſo on to the laſt day of the *month*, which was called Δημήτριος, *Demetrius*, from Demetrius Poliorcetes; before whoſe time, particularly in Solon's laws, it was called ἕνη καὶ νέα, *the old and new*; becauſe the new moon falling out on that day part of it belonged to the old moon, and part to the new. It was alſo called τριακὰς, *the thirtieth*; and that not only in the *months* which conſiſted of thirty days, but alſo in thoſe of twenty-nine; for in theſe, according to ſome accounts the twenty-ſecond day was omitted; or, according to others, the twenty-ninth: but which day ſoever was omitted in computation, the thirtieth was conſtantly retained. Hence, according to Thales's firſt ſcheme, all the *months* were called *months* of thirty days; though, by Solon's regulation, half of them contained only twenty-nine: and the lunar year of Athens was called a year of three hundred and fifty days; though really after Solon's time, it conſiſted of no more than three hundred and fifty-four. Vide Petr. Archæol. Gr. lib. ii. cap. 30.

The names of the *months* being various in different parts of Greece, it will be ſufficient particularly to conſider thoſe of Athens, barely mentioning thoſe of others that correſpond with them. 1. *Hecatombæon*, or ECATOMBÆON. 2. METAGITNION. 3. BOEDROMION. 4. MAIMACTERION. 5. PYANEPSION. 6. ANTHESTERION. 7. POSIDION. 8. GAMELION. 9. ELAPHEBOLION. 10. MUNYCHION. 11. THARGELION. 12. SCIROPHORION.

As the Roman *months* were the ſame with thoſe now in uſe among the Europeans, we ſhall only refer to the article CALENDS, where the manner of their computation is explained.

The Hebrew *months* were originally reckoned in order, as the firſt, ſecond, &c. but after the Babyloniſh captivity, the Iſraelites borrowed the names of their *months* from the Chaldeans and Perſians: and they were diſtinguiſhed in the ſacred and civil year as follows. In the ſacred year, *Niſan*, anſwering to our March, *Iyar* to April, *Sivan* to May, *Thammuz* to June, *Ab* to July, *Elul* to Auguſt. *Tizri* to September, *Marſcheſvan* to October, *Caſlev* to November, *Tebet* to December, *Schbat* to January, and *Adar* to February. In the civil year, *Tizri* correſponding to September, *Marſcheſvan* to October, *Caſlev* to November, *Tebet* to December, *Schbat* to January, *Adar* to February, *Niſan* to March, *Iyar* to April, *Sivan* to May, *Thammuz* to June, *Ab* to July, and *Elul* to Auguſt.

Time, we have obſerved, is duration marked out for certain uſes, and meaſured by the motions of the heavenly bodies.

Hence reſult divers kinds of years, and *months*, according to the particular luminary by whoſe revolutions they are determined, and the particular purpoſes they are deſtined for: as, *ſolar months*, *lunar months*, *civil months*, *aſtronomical months*, &c.

MONTH, *ſolar*, is the ſpace of time wherein the ſun moves through one entire ſign of the ecliptic.

Hence, if regard be had to the ſun's true motion, the *ſolar months* will be unequal; ſince the ſun is longer in paſſing through the ſummer ſigns, than through thoſe of the winter.

But as he conſtantly travels through all the twelve in 365 days, 5 hours, and 49 minutes, the quantity of a mean *month* will be had by dividing that number by 12. On this principle, the quantity of a *ſolar month* will be found 30 days, 10 hours, 29 minutes, 5 ſeconds.

MONTH, *lunar*, are either *ſynodical*, *periodical*, or *illuminative*.

MONTH, *lunar ſynodical*, called alſo, abſolutely, *lunar* MONTH, and *lunation*, is the ſpace of time between two conjunctions of the moon with the ſun; or between two new moons. See SYNODICAL *month*, and LUNATION. The quantity of the *ſynodical month* is 29 days, 12 hours, 44′, 3″, 11‴. See MOON.

MONTH, *lunar periodical*, is the ſpace of time wherein the moon makes her round through the zodiac, or wherein ſhe returns to the ſame point.

The quantity of this *month* is 27 days, 7 hours, 43′, 8″.

The ancient Romans made uſe of *lunar months*, and made them alternately of 29 and 30 days: and they marked the days of each *month* by three terms, viz. *calends*, *nones*, and *ides*.

MONTH, *lunar illuminative*, is the ſpace from the firſt time of the moon's appearance after new moon, to her firſt appearance after the new moon following.

Hence, as the moon appears ſometimes ſooner after the new moon, and ſometimes later; the quantity of the *illuminative month* is not always the ſame. By this *month* the Turks and Arabs reckon.

MONTH, *aſtronomical* or *natural*, is that meaſured by ſome exact interval correſponding to the motion of the ſun, or moon.

Such are the lunar and ſolar *months* above mentioned.

Where note, that theſe *months* can be of no uſe in civil life, where it is required that the *months* begin and end on ſome certain days. For this reaſon, recourſe is had to another form of *months*.

MONTH, *civil*, or *common*, is an interval of a certain num-

ber of whole days, approaching nearly to the quantity of some astronomical, either lunar, or solar *month*.

Civil months are various, according to the astronomical *month* they are accommodated to.

MONTHS, *civil lunar*, are to consist alternately of 29 and 30 days. Thus will two *civil months* be equal to two astronomical ones, abating for the odd minutes; and, consequently, the new moon will be hereby kept to the first day of each such *civil month* for a long time together. However to make them keep constant pace with the *civil months*, at the end of each 948 *months*, a month of 29 days must be added; or else every 33d *month* must consist of 30 days.

This was the *month* in civil or common use among the Jews, Greeks, and Romans, till the time of Julius Cæsar.

MONTHS, *civil solar*, are to consist alternately of 30 and 31 days, excepting one *month* of the twelve, which for every fourth year should consist of 30 days, and for the other years of 29. This form of *civil months* was introduced by Julius Cæsar.

Under Augustus, the sixth *month*, till then from its place called *Sextilis*, was denominated *Augustus*, in honour of that prince; and, to make the compliment yet the greater, a day was added to it: so that it now consisted of 31 days, though till then it had only contained 30; to make up for which, a day was taken from February; so that henceforward it only consisted of 28 days, and every fourth year of 29; though before it had ordinarily consisted of 29 days, &c. and such are the *civil* or CALENDAR *months* which now obtain through Europe.

MONTH, *philosophical*, among *Chemists*, is the space of forty days and nights.

MONTH, *ecclesiastic, embolismic, fence, revolving*. See the adjectives.

MONTH-*minutes*. See CLIMATE.

MONTHLY *courses*. See MENSES.

MONT-PAGNOTE, *the pell of the mountebanks*, an eminence chosen without the reach of the cannon of a place besieged; where curious persons put themselves to see an attack, and the manner of the siege, without being exposed to danger.

MONTIA, *blinks*, in the Linnæan system of *Botany*, the name of a distinct genus of plants of the *triandria trigynia* class; the characters of which are these: the cup is a perianthium compoled of two oval, hollow, obtuse, and erect leaves, which remain when the flower is fallen; the flower is compoled of one irregular petal; the ftamina are three capillary filaments, of the length of the flower; the antheræ are fmall; the germen of the piftillum is of a turbinated form; the ftyles are three, hairy and expanded; the ftigmata are fimple; the fruit is a capfule of a turbinated form obtufe, of one cell, feparated by three valves; the feeds are three in number and roundifh. There is only one fpecies.

MONTIFRINGILLA, in *Zoology*, the name of a bird, known in Engliih by the name of the BRAMBLE, *brambling, or mountain-finch*; and called, by the ancients, *ærithus*.

MONUMENT, *monumentum*, of *monere*, to *admonish, admonish*, in *Architecture*, a building deftined to preferve the memory of the perfon who raifed it, or of him for whom it was raifed: fuch are, a triumphal arch, a mauloleum, a pyramid, &c.

The firft monuments, which the ancients erected, were the ftones which they laid over their tombs, whereon they wrote the names and actions of the deceafed.

Thefe ftones were diftinguifhed, by various names, according as their figures were different. The Greeks gave the name of *ftelæ*, στλαι, to fuch as were fquare in their bafe, and preferved the fame depth throughout their whole length; whence we derived our fquare pilafters, or Attic columns. They called thofe *ftyles*, στυλοι, which, being round in their bafe, ended in a point at top, which gave occafion to the invention of diminifhed columns.

The name *pyramids* they gave to thofe which were fquare at the foot, and determined in a point at top, in manner of a funeral pile.

And the name *obelifc*, to thofe whofe bafes were more in length than in breadth, and which rofe, ftill leffening, to a very great height, refembling the figure of the fuits or inftruments ufed by the ancients in roafting the flefh of their facrifices, which they called *obeli*, οβελοι.

MONUMENT, *the*, abfolutely fo called among us, denotes a magnificent pillar, defigned by fir Chriftopher Wren, erected by order of parliament, in memory of the burning of the city of London, anno 1666, in the very place where the fire began.

This pillar was begun in 1671, and finifhed in 1677. It is of the Doric order, fluted, 202 feet high from the ground, and fifteen feet in diameter, of folid Portland ftone, with a ftone-cafe in the middle of black marble, containing 345 fteps. The loweft part of the pedeftal is 28 feet fquare, and its altitude 40 feet; the front being enriched with curious baflo reliefs. It has a balcony within 32 feet of the top, where is a curious and fpacious blazing urn of gilt brafs.

MONYCHA, formed of *μονος, fingle*, and *ονυξ, hoof*, an epithet applied by naturalifts to thofe animals whofe hoofs are fingle and undivided; fuch are the horfe, and the like.

MOOD, or MODE, in *Logic*, called alfo *Syllogiftic* MOOD, is a proper difpofition of the feveral propofitions of a fyllogifm, in refpect of quantity and quality.

By proper difpofition, we mean fuch wherein the antecedent being true, the confequent, in virtue of the form, cannot be falfe. So that all thofe modes or manners of fyllogifms are at once excluded, where no conclufion formally follows; or where the antecedent being true, a falfe conclufion may be drawn from it.

There are two kinds of *moods*; the one *direct*, the other *indirect*.

MOOD, *direct*, is that wherein the conclufion is drawn from the premifes directly and immediately: as, every animal is a living thing; every man is an animal; therefore every man is a living thing.

MOOD, *indirect*, is that wherein the conclufion is not inferred immediately from the premifes, but follows from them by means of a converfion: as, every animal is a living thing; every man is an animal; therefore fome living thing is a man. Thefe are fourteen direct moods; whereof four belong to the firft figure, four to the fecond, and fix to the third. See FIGURE.

They are denoted by fo many artificial words formed for that purpofe; viz. 1. *Barbara, celarent, darii, ferio*. 2. *Baroko, cefare, cameftres, feftino*. 3. *Darapti, felapton, disamis, datisi, bocardo, ferifon*. 4. *Bamalip, calentes, dimatis, fefapmo, fresifon*.

The ufe and effect of which words fee under the fyllables, and the letters wherein the fyllables confift. Each word, e. g. conftits of three fyllables, denoting the three propofitions of a fyllogifm; viz. major, minor, and conclufion. Add, that the letters of each fyllable are either vowels or confonants: the vowels are *a*, which denotes an univerfal affirmative propofition; *e*, an univerfal negative; *i*, a particular affirmative; and *o*, a particular negative.

Thus, *barbara* is a fyllogifm or *mood* of the firft figure, confifting of three univerfal affirmative propofitions: *baralip* of the fourth figure, confifting of two univerfal affirmative premifes, and a particular affirmative conclufion. The confonants are chiefly of ufe in the REDUCTION of fyllogifms.

MOOD, or MODE, in *Grammar*, is ufed to fignify the different manners of conjugating verbs, agreeably to the different actions or affections to be expreffed; as fhowing, commanding, wifhing, &c.

Hence arife five *moods*; viz. the *indicative, imperative, optative, fubjunctive*, and *infinitive*; which fee.

Some grammarians reckon but four *moods*, confounding the optative with the fubjunctive; and fome make fix, dividing the optative into potential and optative.

The Greeks have five *moods* of verbs different in termination; but the Latins have only four. In Engliih the terminations are the fame in all the *moods*.

For the origin of *moods*, it may be obferved, that verbs are of that kind of words which fignify the manner and form of our thought: whereof the principle is affirmation. Verbs are alfo formed to receive different inflexions, as the affirmation regards different perfons, and different times: whence arife the tenfes and perfons of verbs.

But, befides thefe, men have thought fit to invent other inflexions, to explain what paffes in their mind ftill more diftinctly: for, in the firft place, they conidered, that, befides the fimple affirmations, as *I love, he loves*, there were others modified and conditional, as, *if he loved, though he fhould love*: and the better to diftinguifh thefe affirmations from the others, they doubled the inflexions of thofe tenfes or times; making fome ferve for fimple affirmations, as, *I love, he loves*; and referving the reft for affirmations that were modified, as, *if he fhould love, might he have loved*. Yet they kept not fteadily to their rules; but fometimes made ufe of fimple inflexions to expreis affirmations that were modified: as, *if he come*, for *if he fhould come*. And it is from this kind of reflection, that grammarians have formed the *mood* they call *fubjunctive*.

But farther, befides the affirmation, the action of our mind may be taken for a *mood*, or manner of our thought: and men have found themfelves under a neceffity of expreffing what they *will*, as well as what they *know*. Now we may will a thing in feveral manners; whereof there are three which may be conidered as the principal. Firft then, we fometimes will things which do not depend

depend on ourselves; and in that case we only will them by a bare wish, which the Latins express by the particle *utinam*; and we by *please God*. Some languages, for instance the Greek, have invented particular inflexions for this end; whence the grammarians have taken occasion to call this the *optative mood*: and there seems something like both in the French, Italian, and Spanish tongues, in regard these have a kind of triple tenses; but in Latin, English, &c. the same inflexions serve for the subjunctive, and for the optative. For this reason, one may very well retrench this *mood* from the Latin conjugations; it being the different inflexions that make *moods*, not the different manners of signifying, which may be varied to infinity.

We sometimes will in another manner; as when we are content a thing should come to pass, though we do not absolutely desire it; as when Terence says, *profundat perdat, perdas, lex hanc fecit, fecit, peristi*. Men might have invented a particular inflexion to express this movement, as in Greek they have done to express a simple desire: but they have not done it; and, in lieu thereof, they make use of the subjunctive. In English, we add the particle *let*, let him spend, &c. Authors call this the *permissive mood*, or *concessive mood*.

The third manner of willing is, when what we desire, depends on another person, of whom we can obtain it, and we signify our will that he do it. This is the motion we use, when we command or pray; and to express this motion, was invented the *mood* we call *imperative*; which has no first person in the singular, because a man, properly speaking, cannot command himself: in some languages it has no third person, because, in strictness, a man cannot command any person, but him to whom he speaks and addresses himself. And in regard the command or prayer always relates to what is to come, it happens that the imperative *mood*, and the future tense, are frequently used for each other (especially in the Hebrew); as, *non occides, thou shalt not kill, for do not kill*. Hence some grammarians place the imperative among the number of futures.

Of all the *moods* we have mentioned, the oriental languages have none but the last, which is the imperative; and, on the contrary, the modern languages have none of them any particular inflexion for the imperative. The method we take for it in English, is either to omit the pronoun, or transpose it: thus, I love, is a simple affirmation; love, an imperative: we love, an affirmation; love we, an imperative.

In explaining the origin of *moods*, the ingenious Mr. Harris observes, that the soul's leading powers are those of perception and volition; and that all speech or discourse is a publishing either a certain perception or volition. Hence then, according as we exhibit it either in a different part, or after a different manner, the variety of *moods*. If we simply declare or indicate something to be, or not to be, whether a perception or volition, this constitutes the declarative or indicative *mood*. If we affect something possible only, and in the number of contingents, this makes the potential *mood*. When this is subjoined to the indicative, and used, as it usually is, to denote the end or final cause, it is the subjunctive. When we address others, in order to have some perception informed, or some volition gratified, we form new modes of speaking: if we interrogate, it is the interrogative *mood*: if we require, it is the requisitive, which, with respect to inferiors, is imperative; and, with respect to equals and superiors, precative or optative. The indicative, potential, interrogative, and requisitive *moods* have their foundation in nature; and, therefore, certain marks or signs of them have been introduced into language, that we may be enabled by our discourse to signify them to one another: so that *moods* are, in fact, no more than so many literal forms, intended to express these useful distinctions. All these *moods*, with their respective tenses, the verb being considered as denoting an attribute, have always reference to some person or substance. But there is another *mood* or form, under which verbs sometimes appear, where they have no reference at all to persons or substances: there, from their indefinite nature, are called INFINITIVES. Hermes, p. 140, &c.

MOOR, in *Philosophy*, and *Music*. See MOOR.

MOON, *luna*, ☽, in *Astronomy*, one of the heavenly bodies, usually ranked among the planets; but with more propriety accounted a satellite, or secondary planet.

The *moon* is an attendant of our earth, whom she respects as a centre, and in whose neighbourhood she is constantly found; insomuch as, if viewed from the sun, she would never appear to depart from us by an angle greater than ten minutes.

As all the other planets move primarily round the sun, so does the *moon* round the earth: her orbit is an ellipsis, in which she is retained by the force of gravity; performing her revolution round the earth, from change to change, in 29 days, 12 hours, and 44 minutes, and round the sun with it every year: tho' she goes round her orbit in 27 days, 7 hours, 43 minutes, moving about 2190 miles every hour; and turns round her axis exactly in the time that she goes round the earth, which is the reason of her keeping always the same side towards us; and that her day and night taken together are as long as our lunar month.

The mean distance of the *moon* from the earth is 60½ semi-diameters of the earth; which is equivalent to 240,000 miles. The mean eccentricity of her orbit is 11/2 of her mean distance, or 10 miles 4,000, which makes a considerable variation in that mean distance.

The *moon*'s diameter is to that of the earth, as 100 to 365, or 11 to 40.15, or 2180 miles: its mean apparent diameter is 31 minutes 16½, and that of the sun 32 minutes 12 seconds. Its mean diameter, as seen from the sun, is 6 seconds.

The *moon*'s surface contains 14,898,750 square miles, and its solidity 5,208,240,000 cubical ones. The density of the *moon*'s body is to that of the earth, as 48,972 to 370,141; to that of the sun, as 48,911 to 19,020; its quantity of matter to that of the earth, nearly as 1 to 39.15; the force of gravity on its surface, is to that on the surface of the earth, as 1392 to 4077.8; and the *moon*'s bulk to that of the earth as 1 to 1. The *moon* has scarce any difference of seasons; because her axis is almost perpendicular to the ecliptic.

The full *moon* appears to the naked eye broader than a circular object subtending an equal angle seen by perfect vision. In a moon of three or four days old the illuminated part appears too broad, in proportion to the obscure part, and likewise seems to extend more outwards, or to have a greater diameter that the obscure part. Also, in an eclipse of the sun or *moon*, the bright part appears too broad in proportion to the dark part, and the eclipse appears less than it really is.

This observation was made by Horrox, and is accounted for by Dr. Jurin, in his Essay upon distinct and indistinct Vision.

In the Philosophical Transactions, N° 473, we have a new method of computing the appulses of the *moon* to the fixed stars and planets; as also of eclipses of the earth, commonly called eclipses of the *sun*, by Mr. Gerbet, professor of the mathematics at Gresham.

MOON, *phenomena of the*. The different appearances of the *moon* are very numerous; sometimes she is increasing, then waning; sometimes horned, then semicircular; sometimes gibbous, then full and round.

Sometimes, again, she illumines us the whole night; sometimes only a part of it; sometimes she is found in the southern hemisphere, sometimes in the northern; all which variations having been first observed by Endymion, an ancient Grecian, who watched her motions, she was fabled to have fallen in love with him.

The source of most of these appearances is, that the *moon* is a dark, opake, and spherical body, and only shines with the light she receives from the sun; whence only that half turned towards him, at any instant, can be illuminated, the opposite half remaining in native darkness. The face of the *moon* visible on our earth, is that part of her body turned towards the earth; whence, according to the various positions of the *moon*, with regard to the sun and earth, we observe different degrees of illumination; sometimes a large, and sometimes a less portion of the enlightened surface being visible.

MOON, *phases of the*. To conceive the lunar phases, let S (*Tab. Astronomy, fig.* 13.) represent the sun; T the earth, RTS a portion of the earth's orbit, and ABDEFG the orbit of the *moon*, wherein she revolves round the earth, in the space of a month, advancing from west to east: connect the centres of the sun and *moon* by the right line S L, and through the centre of the *moon* imagine a plane M L N to pass perpendicular to the line S L; the section of that plane, with the surface of the *moon*, will give the line that bounds light and darkness, and separates the illumined face from the dark one.

Connect the centres of the earth and *moon* by T L, perpendicular to a plane P L O, passing through the centre of the *moon*: that plane will give on the surface of the *moon* the circle that distinguishes the visible hemisphere, or that towards us, from the invisible one, and therefore called *the circle of vision*. Whence it appears, that, whenever the *moon* is in A, the circle bounding light and darkness and the circle of vision coincides; so that all the illumined face of the *moon* will be turned towards the earth: in which case the *moon* is, with respect to us, full, and shines the whole night; with respect to the sun, she is in opposition; in regard the sun and *moon* are then seen in opposite parts of the heavens, the one

rising

filling when the other sets. But it is to be observed, that the *moon*'s disc is not perfectly round when she is full, in the highest or lowest part of her orbit, because we have not a full view of her enlightened side at that time. When *full*, in the highest part of her orbit, a small deficiency appears on her lower edge; and the contrary when full in the lowest part of her orbit.

When the *moon* arrives at B, the whole illuminated disc M P N is not turned towards the earth; so that the visible illumination will be short of a circle; and the *moon* will appear gibbous, as in B.

When she reaches C, where the angle C T S is nearly right, there only one half of the illumined disc is turned towards the earth, and then we observe a *half moon*, as in C; and she is said to be *dichotomized*, or *bisected*.

In this situation the sun and *moon* are a fourth part of a circle removed from each other; and the *moon* is said to be in a *quadrate aspect*, or to be in her *quadrature*.

The *moon* arriving at D, only a small part of the illumined face M P N is turned towards the earth; for which reason the small part that shines upon us will be seen falcated, or bent into narrow angles, or horns as in D.

The inclination of that part of the ecliptic to the horizon, to which the *moon* is at any time when horned, may be known by the position of her horns; for a right line touching their points is perpendicular to the ecliptic. And as the angle, which the *moon*'s orbit makes with the ecliptic, can never raise her above, nor depress her below the ecliptic, more than two minutes of a degree, as seen from the sun; it can have no sensible effect upon the position of her horns. Therefore, if a quadrant be held up, so as one of its edges may seem to touch the *moon*'s horns, the graduated side being kept towards the eye, and as far from the eye as it can be conveniently held, the arc between the plumb-line and the edge of the quadrant, which seems to touch the *moon*'s horns, will shew the inclination of that part of the ecliptic to the horizon. And the arc, between the other edge of the quadrant and plumb-line, will shew the inclination of a line, touching the *moon*'s horns, to the horizon.

At last, the *moon* arriving at E, shews no part of her illumined face at all to the earth, as in E; this position we call the *new moon*, and she is then said to be in conjunction with the sun; the sun and *moon* being in the same point of the ecliptic.

As the *moon* advances towards F, she resumes her horns; and as before the new *moon* the horns were turned westward, so now they change their position, and look eastward: when she comes to G, she is again in quadrate aspect with the sun; in H she is gibbous; and in A she is again full.

Here the arch E L, or the angle S T L, contained under lines drawn from the centres of the sun and *moon* to that of the earth, is called *the elongation of the moon* from the sun: and the arch M O, which is the portion of the illumined circle M O N, that is turned towards us, and which is the measure of the angle that the circle bounding light and darkness, and the circle of vision, make with each other, is every where nearly similar to the arch of elongation E L; or, which is the same thing, the angle S T L, is nearly equal to the angle M L O: as is demonstrated by geometers.

To delineate the MOON*'s phases for any time.* Let the circle C O B P (*fig.* 14.) represent the *moon*'s disc turned towards the earth, and let O P be the line in which the semicircle O C P is projected, which suppose cut at right angles by the diameter B C; then making L P the radius, take L F equal to the co-sine of the elongation of the *moon*; and upon B C, as the greater axis, and L F the less, describe the semiellipsis B F C; this ellipsis will cut off from the *moon*'s disc the portion B F C P, of the illumined face visible on the earth.

As the *moon* illumines the earth by a light reflected from the sun, so she is reciprocally illumined by the earth, which reflects the sun's rays to the surface of the *moon*, and that much more abundantly than she receives them from the *moon*. For the surface of the earth is above 13 times greater than that of the *moon*; and, therefore, supposing the texture of each body alike, as to the power of reflecting, the earth must return 13 times more light to the *moon* than she receives from it. In new *moons*, the illumined side of the earth is turned fully towards the *moon*, and will, therefore, at that time, illumine the dark side of the *moon*; and then the lunar inhabitants (if such there be) will have a full earth, as we, in a similar position, have a full *moon*: and hence arises that dim light observed in the old and new *moons*; whereby, besides the bright horns, we perceive somewhat more of her body behind them, though very obscurely. When the *moon* comes to be in opposition to the sun, the earth, seen from the *moon*, will appear in conjunction with him, and its dark side will be turned towards the *moon*; in which position the earth will disappear to the *moon*, as she does to us at the time of the new *moon*, or in her conjunction with the sun. After this, the lunar inhabitants will see the earth in an horned figure. In fine, the earth will present all the same phases to the *moon*, as the *moon* does to the earth. But from one half of the *moon*, the earth is never seen at all; from the middle of the other half it is always seen over head, turning round almost thirty times as quick as the *moon* does. From the circle which limits our view of the *moon*, only one half of the earth's side next her is seen; the other half being hid below the horizon of all places on that circle. To her the earth seems to be the biggest body in the universe; for it appears thirteen times as big as she does to us. As the earth turns round its axis, the several continents, seas, and islands appear to the *moon*'s inhabitants like so many spots of different forms and brightness, moving over its surface; but much faster at some times than others, as our clouds cover or leave them. By these spots, the Lunarians can determine the time of the earth's diurnal motion, just as we do the motion of the sun: and perhaps they measure their time by the motion of the earth's spots; for they cannot have a truer dial.

Dr. Hook, accounting for the reason why the *moon*'s light affords no visible heat, observes, that the quantity of light, which falls on the hemisphere of the full *moon*, is rarified into a sphere 288 times greater in diameter than the *moon*, before it arrives at us; and, consequently, that the *moon*'s light is 104368 times weaker than that of the sun. It would, therefore, require 104368 full *moons* to give a light and heat equal to that of the sun at noon.

Dr. Smith has endeavoured to shew, in his book on Optics, that the light of the full *moon* is but equal to a 90 thousandth part of the common light of the day when the sun is hidden by a cloud. See LIGHT.

MOON, *course and motion of the.* Though the *moon* finishes its course in 27 days 7 hours 43′, which interval we call a *periodical* month, yet she is longer in passing from one conjunction to another; which space we call a *synodical* month, or a *lunation*. The reason is, that while the *moon* is performing its course round the earth in its own orbit, the earth and *moon* are making their progress round the sun, and both are advanced almost a whole sign towards the east, so that the point of the orbit, which, in the former position, was in a right line passing through the centres of the earth and sun, is now more westerly than the sun: and, therefore, when the *moon* is arrived again at that point, it will not yet be seen in conjunction with the sun; nor will the lunation be completed in less than 29 days and an half.

Were the plane of the *moon*'s orbit coincident with the plane of the ecliptic, i. e. were the earth and *moon* both moved in the same plane, the *moon*'s way in the heaven, viewed from the earth, would appear just the same with that of the sun; with this only difference, that the sun would be found to describe his circle in the space of a year, and the *moon* her's in a month. But this is not the case; for the two planes cut each other in a right line, passing through the centre of the earth, and are inclined to each other in an angle of about five degrees eighteen minutes.

Suppose, e. g. A B (*fig.* 15.) a portion of the earth's orbit, T the earth, and C E D F the *moon*'s orbit, wherein is the centre of the earth; from the same centre T, in the plane of the ecliptic, describe another circle C G D H, whose semidiameter is equal to that of the *moon*'s orbit. Now these two circles, being in several planes, and having the same centre, will intersect each other in a line D C, passing through the centre of the earth. Consequently, C E D, one half of the orbit of the *moon*, will be raised above the plane of the circle C G H, towards the north; and D F C, the other half, will be sunk below towards the south. The right line D C, wherein the two circles intersect each other, is called *the line of the nodes*; and the points of the angles C and D, *the nodes*: whereof that where the *moon* ascends above the plane of the ecliptic, northwards, is called, *the ascending node*, and *the head of the dragon's* and the other, D, *the descending node*, and *the dragon's tails* and the interval of time between the *moon*'s going from the ascending node, and returning to it, *an antic month*.

If the line of the nodes were immoveable, that is, if it had no other motion, but that whereby it is carried round the sun, it would still look towards the same point of the ecliptic; i. e. it would always keep parallel to itself: but it is found by observation, that the line of the nodes constantly changes place, and shifts in situation from east to west, contrary to the order of the signs; and, by a retrograde motion, finishes its circuit in about nineteen years; in which time each of the nodes returns to that point of the ecliptic whence it before receded.

Hence it follows, that the *moon* is never precisely in the ecliptic,

ecliptic, but twice each period; viz. when she is in the nodes. Throughout the rest of her course she deviates from it, being nearer or farther from the ecliptic, as she is nearer or farther from the nodes. In the points F and E she is at her greatest distance from the nodes; which points are therefore called *her limits of north and south latitude*.

The *moon*'s distance from the nodes, or rather from the ecliptic, is called her *latitude*, which is measured by an arch of a circle drawn through the *moon*, perpendicular to the ecliptic, and intercepted between the *moon* and the ecliptic. The *moon*'s latitude, when at the greatest, as in E or F, never exceeds 5 degrees and about 18 minutes; which latitude is the measure of the angles at the nodes.

It appears by observation, that the *moon*'s distance from the earth is continually changing; and that she is always either drawing nearer, or going farther from us. The reason is, that the *moon* does not move in a circular orbit, which has the earth for its centre; but in an elliptic orbit (as represented in *fig.* 16.) one of whose foci is the centre of the earth: A P represents the greater axis of the ellipsis, and the line of the apsides; and T C the eccentricity: the point A, which is the highest apsis, is called the *apogee* of the *moon*; and P, the lower apsis, is the *moon's perigee*, or the point wherein she comes nearest the earth.

Besides, there is reason to believe that the *moon* is somewhat nearer the earth now than she was formerly; her periodical month being shorter than it was in former ages. For our astronomical tables, which in the present age shew the times of solar and lunar eclipses to great precision, do not answer so well for ancient eclipses.

The space of time wherein the *moon*, going from the apogee, returns to it again, is called the *anomalistic month*.

If the *moon*'s orbit had no other motion but that wherewith it is carried round the sun, it would still retain a position parallel to itself, and always point the same way, and be observed in the same point of the ecliptic; but the line of the apsides is likewise observed to be moveable, and to have an angular motion round the earth, from west to east, according to the order of the signs, returning to the same situation in the space of about nine years.

The irregularities of the Moon's *motion*, and that of her orbit, are very considerable. For, 1. when the earth is in her aphelion, the *moon* is in her aphelion likewise; in which case she quickens her pace, and performs her circuit in a shorter time; on the contrary, when the earth is in its perihelion, the *moon* is so too, and then she slackens her motion: and thus she revolves round the earth, in a shorter space, when the earth is in her aphelion than when in her perihelion; so that the periodical months are not all equal.

2. When the *moon* is in her syzygies, i. e. in the line that joins the centres of the earth and sun, which is either in her conjunction or opposition, she moves swifter, *ceteris paribus*, than when in the quadratures.

3. According to the different distances of the *moon* from the syzygies, i. e. from opposition to conjunction, she changes her motion: in the first quarter, that is, from the conjunction to her first quadrature, she abates somewhat of her velocity; which in the second quarter she recovers; in the third quarter she again loses; and in the last she again recovers. This inequality was first discovered by Tycho Brahe, who called it *the moon's variation*.

4. The *moon* moves in an ellipsis, one of whose foci is in the centre of the earth, round which the describes areas proportionable to the time, as the primary planets do round the sun; whence her motion in the perigee must be quickest, and it must be slowest in the apogee.

5. The very orbit of the *moon* is changeable, and does not always persevere in the same figure; its eccentricity being sometimes increased, and sometimes diminished: it is greatest, when the line of the apsides coincides with that of the syzygies; and least, when the line of the apsides cuts the other at right angles.

6. Nor is the apogee of the *moon* without an irregularity; being found to move forward, when it coincides with the line of the syzygies; and backward, when it cuts that line at right angles. Nor is this progress and regress in any measure equal: in the conjunction or opposition, it goes briskly forward; and in the quadratures it moves either slowly forward, stands still, or goes backwards.

7. The motion of the nodes is not uniform; but when the line of the node coincides with that of the syzygies at right angles, they go backward, from east to west; and this sir Isaac Newton shews, is at the rate of 10′, 19″, 24‴, in an hour.

The only equable motion the *moon* has, is that wherewith she turns round her axis exactly in the same space of time, in which she revolves round us in her orbit; whence it happens, that she always turns the same face towards us.

For as the *moon*'s motion round its axis is equal, and yet its motion, or velocity, in its orbit, is unequal, it follows, that when the *moon* is in its perigee, where it moves swiftest in its orbit, that part of its surface, which, on account of its motion in the orbit, would be turned from the earth, is not so entirely; by reason of its motion round its axis. Thus some parts in the limb or margin of the *moon*, sometimes recede from the centre of the disc, and sometimes approach towards it; and some parts, that were before invisible, become conspicuous; which is called *the moon's libration*.

Yet this equability of rotation occasions an apparent irregularity; for the axis of the *moon* not being perpendicular to the plane of her orbit, but a little inclined to it; and this axis, maintaining its parallelism, in its motion round the earth; it must necessarily change its situation, in respect of an observer on the earth; to whom sometimes the one, and sometimes the other pole of the *moon* becomes visible; whence it appears to have a kind of wavering, or vacillation.

Physical cause of the Moon's *motions.* The *moon*, we have observed, moves round the earth by the same laws, and in the same manner, as the earth, and other planets, move round the sun. The solution, therefore, of the lunar motions, in general, comes under those of the earth, and other planets.

As for the particular irregularities in the *moon*'s motion, to which the earth, and other planets, are not subject, they arise from the sun, which acts on, and disturbs her in her ordinary course through her orbit; and are all mechanically deducible from the same great law whereby her general motion is directed; viz. the law of *gravitation* and *attraction*.

Other secondary planets, viz. the satellites of Jupiter and Saturn, are, doubtless, subject to the like irregularities with the *moon*; as being exposed to the same perturbating or disturbing force of the sun; but their distance secures them from our observation.

The laws of the several irregularities in the syzygies, quadratures, &c. see under Syzygies, Quadratures, &c.

We shall, however, in this place, introduce a general view of the Newtonian theory of gravity, as it is applied to the solution of the irregularities of the *moon*'s motion.

It must first be considered, that if the sun acted equally on the earth and *moon*, and always in parallel lines, this action would serve only to restrain them in their annual motions round the sun, and no way affect their actions on each other, or their motions about their common centre of gravity. But because the *moon* is nearer the sun, in one half of her orbit, than the earth is, and farther in the other half of her orbit, and the power of gravity is always greater at a less distance, it follows, that, in one half of her orbit, the *moon* is more attracted than the earth towards the sun, and in the other half less attracted than the earth: and hence irregularities necessarily arise in the motions of the *moon*; the excess, in the first case, and the defect, in the second, of the attraction, becoming a force that disturbs her motion: and besides, the action of the sun, on the earth and *moon*, is not directed in parallel lines, but in lines that meet in the centre of the sun.

In order to understand the effects of these powers, let us suppose that the projectile motions of the earth and *moon* were destroyed, and that they were allowed to fall freely towards the sun. If the *moon* was in conjunction with the sun, or in that part of her orbit which is nearest to him, the *moon* would be more attracted than the earth, and fall with greater velocity towards the sun; so that the distance of the *moon* from the earth would be increased in the fall. If the *moon* was in opposition, or in the part of her orbit which is farthest from the sun, she would be less attracted than the earth by the sun, and would fall with a less velocity, towards the sun than the earth, and the *moon* would be left behind by the earth; so that the distance of the *moon* from the earth would be increased, in this case also. If the *moon* was in one of the quarters, then the earth and *moon* being both attracted towards the centre of the sun, they would both directly descend towards that centre, and, by approaching to the same centre, they would necessarily approach at the same time to each other, and their distance from one another would be diminished, in this case. Now, wherever the action of the sun would increase their distance, if they were allowed to fall towards the sun, there we may be sure the sun's action, by endeavouring to separate them, diminishes their gravity to each

other; wherever the action of the sun would diminish their distance, there the sun's action, by endeavouring to make them approach to one another, increases their gravity to each other: that is, in the conjunction and opposition, their gravity towards each other is diminished by the action of the sun; but in the two quarters it is increased by the action of the sun. To prevent mistaking this matter, it must be remembered, it is not the total action of the sun on them that disturbs their motions, it is only that part of its action by which it tends to separate them, in the first case, to a greater distance from each other; and that part of its action, by which it tends to bring them nearer to each other, in the second case, that has any effect on their motions, with respect to each other. The other, and the far more considerable part has no other effect but to retain them in their annual course, which they perform together about the sun.

In considering, therefore, the effects of the sun's action on the motions of the earth and *moon*, with respect to each other, we need only attend to the excess of its action on the *moon* above its action on the earth, in their conjunction; and we must consider this excess as drawing the *moon* from the earth towards the sun in that place. In the opposition, we need only consider the excess of the action of the sun, on the earth, above its action on the *moon*, and we must consider this excess as drawing the *moon* from the earth, in this place, in a direction opposite to the former, that is, towards the place opposite to where the sun is; because we consider the earth as quiescent, and refer the motion, and all its irregularities to the *moon*. In the quarters, we consider the action of the sun as adding something to the gravity of the *moon* towards the earth.

Suppose the *moon*, setting out from the quarter that precedes the conjunction, with a velocity that would make her describe an exact circle round the earth, if the sun's action had no effect on her; and because her gravity is increased by that action, she must descend towards the earth, and move within that circle: her orbit, there, will be more curve than otherwise it would have been: because this addition to her gravity will make her fall farther at the end of an arc below the tangent drawn at the other end of it; her motion will be accelerated by it, and will continue to be accelerated till she arrives at the ensuing conjunction; because the direction of the action of the sun upon her, during that time, makes an acute angle with the direction of her motion. At the conjunction, her gravity towards the earth being diminished by the action of the sun, her orbit will be less curve there, for that reason; and she will be carried farther from the earth as she moves to the next quarter; and, because the action of the sun makes then an obtuse angle with the direction of her motion, she will be retarded by the same degrees by which she was accelerated before.

Thus she will descend a little towards the earth, as she moves from the first quarter towards the conjunction, and ascend from it, as she moves from the conjunction to the next quarter. The action which disturbs her motion will have a like, and almost equal effect upon her, while she moves in the other half of her orbit, that is, that half of it which is farthest from the sun: she will proceed from the quarter that follows the conjunction with an accelerated motion to the opposition, approaching a little towards the earth, because of the addition made to her gravity, at that quarter, from the action of the sun; and receding from it again, as she goes on from the opposition to the quarter from which we supposed her to set out. The areas described in equal times, by a ray drawn from the *moon* to the earth, will not be equal, but will be accelerated by the conspiring action of the sun, as she moves towards the conjunction or opposition from the quarters that precede them; and will be retarded by the same action, as she moves from the conjunction or opposition to the quarters that succeed them. Newton has computed the quantities of these irregularities from their causes. He finds, that the force added to the gravity of the *moon*, in her quarters, is to the gravity with which she would revolve in a circle about the earth, at her present mean distance, if the sun had no effect on her, as 1 to $178\frac{1}{2}$. He finds the force subducted from her gravity, in the conjunctions and oppositions, to be double of this quantity, and the area described in a given time in the quarters, to be to the area described in the same time in the conjunctions and oppositions, as 10073 to 11073. He finds, that in such an orbit, her distance from the earth in her quarters, would be to her distance in the conjunctions and oppositions, as 70 to 69.

As to the effect of the action of the sun on the nodes, and consequently, on the inclination of the *moon*'s orbit to the ecliptic, see NODES.

Moreover, the action of the sun diminishes the gravity of the *moon* towards the earth, in the conjunctions and oppositions, more than it adds to it in the quarters, and, by diminishing the force which retains the *moon* in her orbit, it increases her distance from the earth and her periodic time: and because the earth and *moon* are nearer the sun in their perihelion than in their aphelion, and the sun acts with a greater force there, so as to subduct more from the *moon*'s gravity towards the earth; it follows, that the *moon* must revolve at a greater distance, and take a longer time to finish her revolution in the perihelion of the earth, than in the aphelion; and this also is conformable to observation.

There is another remarkable irregularity in the *moon*'s motion, that also arises from the action of the sun: which is the progressive motion of the apsides. The *moon* describes an ellipse about the centre of the earth, having one of the foci in that centre. Her greatest and least distances from the earth are in the apsides, or extremities of the longer axis of the ellipse. This is not found to point always to the same place in the heavens, but to move with a progressive motion forwards, so as to finish a revolution round the earth's centre in about nine years.

To understand the reason of this motion of the apsides, we must consider, that, if the gravity of a body decreased less as the distance increases, than according to the regular course of gravity, the body would descend sooner from the higher to the lower apsis, than in half a revolution; and therefore the apsis would recede in that case, for it would move in a contrary direction to the motion of the body, meeting it in its motion. But if the gravity of the body should decrease more as the distance increases, than according to the regular course of gravity, that is, in a higher proportion than as the square of the distance increases, the body would take more than half a revolution to move from the higher to the lower apsis; and, therefore, in that case, the apsides would have a progressive motion in the same direction as the body.

In the quarters, the sun's action adds to the gravity of the *moon*, and the force it adds is greater, as the distance of the *moon* from the earth is greater; so that the action of the sun hinders her gravity towards the earth from decreasing as much while the distance increases, as it ought to do according to the regular course of gravity; and, therefore, while the *moon* is in the quarters, her apsides must recede. In the conjunction and opposition, the action of the sun subducts from the gravity of the *moon* towards the earth, and subducts the more the greater her distance from the earth is, so as to make her gravity decrease more as her distance increases, than according to the regular course of gravity; and therefore, in this case, the apsides are in a progressive motion. Because the action of the sun subducts more in the conjunctions and oppositions from her gravity, than it adds to it in the quarters, and, in general, diminishes more than it augments her gravity; hence it is that the progressive motion of the apsides exceeds the retrograde motion: and, therefore, the apsides are carried round according to the order of the signs. See Maclaurin's Account of Sir Isaac Newton's Phil. Disc. book 1. chap. 4.

We have some observations and tables concerning the *moon*'s motion, by Mr. Richard Dunthorn, in the Philosophical Transactions, N° 482, sec. 13. where he gives a hundred observed longitudes of the *moon* compared with the tables, viz. twenty-five eclipses of the *moon*, taken (except the first) from Flamsteed's Historia Coelestis, the Philosophical Transactions, and the Memoirs of the Royal Academy of Sciences; the two great eclipses of the sun in 1706, and 1715; twenty-five select places of the *moon*, from Flamsteed's Historia Coelestis; and forty-eight of those longitudes of the *moon*, computed from Flamsteed's Observations by Dr. Halley, and printed in the first edition of the Historia Coelestis.

Figure of the MOON'S *path with respect to the sun.* The path of the *moon* is concave towards the sun throughout.

In other secondary planets, as the satellites of the superior planets, that part of the path of these satellites which is nearest the sun, is convex towards the sun, and the rest is concave. And we often find in elementary treatises of astronomy, the *moon*'s path represented in the same manner; that is, as partly convex and partly concave towards the sun; but this is a mistake. For it is to be observed, in general, that the force which bends the course of the satellite into a curve, when the motion is referred to an immoveable plane, is, at the conjunction, the difference of its gravity towards the sun, and of its gravity towards the primary. When the former prevails over the latter, the force that bends the course of the satellite tends toward the sun; and, consequently, the concavity of the path is towards the sun; and this is the case

caſe of the *moon*. When the gravity towards the primary exceeds the gravity towards the ſun, at the conjunction, then the force which bends the courſe of the ſatellite tends toward the primary, and therefore towards the oppoſition of the ſun; conſequently the path is there convex toward the ſun; and this is the caſe of the ſatellites of Jupiter. When theſe two forces are equal, the path has, at the conjunction, what mathematicians call a point of rectitude; in which caſe, however, the path is concave toward the ſun throughout.

If, indeed, the earth had no annual motion, the *moon*'s motion round the earth, and her track in open ſpace, would be always the ſame. But as the earth and *moon* move round the ſun, the *moon*'s real path in the heavens is very different from her viſible path round the earth; the latter being in a progreſſive circle, and the former in a curve of different degrees of concavity, which would be always the ſame in the ſame parts of the heavens, if the *moon* performed a complete number of lunations in a year, without any fractions.

Mr. Ferguſon has ſuggeſted the following familiar idea of the earth's and *moon*'s path. Let a nail in the end of a chariot-wheel repreſent the earth, and a pin in the nave the *moon*; if the body of the chariot be propped up, ſo as to keep that wheel from touching the ground, and the wheel be then turned round by hand, the pin will deſcribe a circle both round the nail, and in the ſpace it moves through. But if the props be taken away, the horſes put to, and the chariot driven over a piece of ground which is circularly convex; the nail in the axle will deſcribe a circular curve, and the pin in the nave will ſtill deſcribe a circle round the progreſſive nail in the axle, but not in the ſpace through which it moves. In this caſe, the curve deſcribed by the nail will reſemble in miniature as much of the earth's annual path round the ſun, as it deſcribes whilſt the *moon* goes as often round the earth as the pin does round the nail: and the curve deſcribed by the nail will have ſome reſemblance to the *moon*'s path during ſo many lunations.

Let us now ſuppoſe that the radius of the circular curve, deſcribed by the nail in the axle, is to the radius of the circle, which the pin in the nave deſcribes round the axle, as 337½ to 1; which is the proportion of the radius or ſemidiameter of the earth's orbit to that of the *moon*'s; or of the circular curve A 1 2 3 4 5 6 7 B, &c. (*Tab.* IV. *Aſtronomy, fig.* 81.) to the little circle *a*, and then, whilſt the progreſſive nail deſcribes the ſaid curve from A to E, the pin will go once round the nail, with regard to the centre of its path, and, in ſo doing, will deſcribe the curve *a b c d e*. The former will be a true repreſentation of the earth's path for one lunation, and the latter of the *moon*'s for that time. Here we may ſet aſide the inequalities of the *moon*'s motion, and alſo the earth's moving round its common centre of gravity, and the *moon*'s: all which, if they were truly copied in this experiment, would not ſenſibly alter the figure of the paths deſcribed by the nail and pin, even though they ſhould rub againſt a plain upright ſurface all the way, and leave their tracks viſible upon it. And if the chariot was driven forward on ſuch a convex piece of ground, ſo as to turn the wheel ſeveral times round, the track of the pin in the nave would ſtill be concave toward the centre of the circular curve deſcribed by the pin in the axle; as the *moon*'s path is always concave to the ſun in the centre of the earth's annual orbit.

In this diagram, the thickeſt curve line A B C D E, with the numeral figures ſet to it, repreſents as much of the earth's annual orbit as it deſcribes in 32 days from weſt to eaſt; the little circles at *a, b, c, d, e*, ſhew the *moon*'s orbit in due proportion to the earth's; and the ſmalleſt curve *a b c d e f* repreſents the line of the *moon*'s path in the heavens for 32 days, accounted from any particular new *moon* at *a*.

The ſun is ſuppoſed to be in the centre of the curve A 1 2 3 4 5 6 7 B, &c. and the ſmall dotted circles upon it repreſent the *moon*'s orbit, of which the radius is in the ſame proportion to the earth's path, in this ſcheme, that the radius of the *moon*'s orbit, in the heavens, bears to the radius of the earth's annual path round the ſun; that is, as 240,000 to 81,000,000, or as 1 to 337½.

When the earth is at *a*, the new *moon* is at *a*; and in the ſeven days that the earth deſcribes the curve 1 2 3 4 5 6 7, the *moon*, in accompanying the earth, deſcribes the curve *a b*; and is in her firſt quarter at *b* when the earth is at B. As the earth deſcribes the curve B 8 9 10 11 12 13 14, the *moon* deſcribes the curve *b c*; and is at *c*, oppoſite to the ſun, when the earth is at C. Whilſt the earth deſcribes the curve C 15 16 17 18 19 20 21 22, the *moon* deſcribes the curve *c d*; and is in her third quarter at *d* when the earth is at D. And, laſtly, whilſt the earth deſcribes the curve D 23 24 25 26 27 28 29, the *moon* deſcribes the curve *d e*; and is again in conjunction at *e* with the ſun, when the earth is at E, between the 29th and 30th day of the *moon*'s age, accounted by the numeral figures from the new *moon* at A. In deſcribing the curve *a b c d e*, the *moon* goes round the progreſſive earth as really as if ſhe had kept in the dotted circle A, and the earth continued immoveable in the centre of that circle.

And thus we ſee, that although the *moon* goes round the earth in a circle, with reſpect to the earth's centre, her real path in the heavens is not very different in appearance from the earth's path. To ſhew that the *moon*'s path is concave to the ſun, even at the time of change, it is carried on a little farther into a ſecond lunation, as to *f*.

The *moon*'s abſolute motion from her change to her firſt quarter, or from *a* to *b*, is ſo much ſlower than the earth's, that ſhe falls 240 thouſand miles (equal to the ſemidiameter of her orbit) behind the earth at her firſt quarter in *b*, when the earth is in B; that is, ſhe falls back a ſpace equal to her diſtance from the earth. From that time her motion is gradually accelerated to her oppoſition or full at *c*, and then ſhe is come up as far as the earth, having regained what ſhe loſt in her firſt quarter from *a* to *b*. From the full to the laſt quarter at *d*, her motion continues accelerated, ſo as to be juſt as far before the earth at *d*, as ſhe was behind it at her firſt quarter in *b*. But from *d* to *e* her motion is retarded ſo, that ſhe loſes as much with reſpect to the earth, as is equal to her diſtance from it, or to the ſemidiameter of her orbit; and by that means ſhe comes to *e*, and is then in conjunction with the ſun, as ſeen from the earth at E. Hence we find, that the *moon*'s abſolute motion is ſlower than the earth's, from her third quarter to her firſt; and ſwifter than the earth's, from her firſt quarter to her third: her path being leſs curved than the earth's in the former caſe, and more in the latter. Yet it is ſtill bent the ſame way towards the ſun; for if we imagine the concavity of the earth's orbit to be meaſured by the length of a perpendicular line C *g*, let down from the earth's place upon the ſtraight line *b d*, at the full of the *moon*, and connecting the places of the earth at the end of the *moon*'s firſt and third quarters, that length will be about 640 thouſand miles; and the *moon*, when new, only approaching nearer to the ſun, by 240 thouſand miles, than the earth is, the length of the perpendicular let down from her place, at that time, upon the ſame ſtrait line, and which ſhews the concavity of that part of her path, will be about 400 thouſand miles.

The gravity of the *moon* towards the ſun has been found to be greater, at her conjunction, than her gravity towards the earth, ſo that the point of equal attraction, where thoſe two powers would ſuſtain each other, falls then between the *moon* and earth: and ſince the quantity of matter in the ſun is almoſt 230 thouſand times as great as the quantity of matter in the earth, and the attraction of each body diminiſhes as the ſquare of the diſtance from it increaſes, it may be eaſily found, that this point of equal attraction between the earth and the ſun is about 70 thouſand times nearer the earth than the *moon* is at her change: whence ſome, and particularly Mr. Baxter, author of Matho, have apprehended, that either the parallax of the ſun is very different from that which is aſſigned by aſtronomers, or that the *moon* ought neceſſarily to abandon the earth; becauſe ſhe is conſiderably more attracted by the ſun than by the earth at that time. This apprehenſion may be removed eaſily, by attending to what has been ſhewn by Sir Iſaac Newton, and is illuſtrated by vulgar experiments concerning the motions of bodies about one another, that are all acted upon by a third force in the ſame direction. Their relative motions not being in the leaſt diſturbed by this third force, if it act equally upon them in parallel lines; as the relative motions of the ſhips in a fleet, carried away by a current, are no way affected by it, if it act equally upon them; or as the rotation of a bullet or bomb, about its axis, while it is projected in the air; or the figure of a drop of falling rain, are not at all affected by the gravity of the particles of which they are made up, towards the earth. The *moon* is ſo near the earth, and both of them ſo far from the ſun, that the attractive power of the ſun may be conſidered as equal on both; and, therefore, the *moon* will continue to circulate round the earth in the ſame manner as if the ſun did not attract them at all. It is to the inequality of the action of the ſun, upon the earth and *moon*; and the want of paralleliſm in the directions of theſe actions, only, that we are to aſcribe the irregularities in the motion of the *moon*.

But

But it may contribute farther towards removing this difficulty to obſerve, that if the abſolute velocity of the *moon*, at the conjunction, was leſs than that which is requiſite to carry a body in a circle there around the ſun, ſuppoſing this body to be acted on by the ſame force which acts there on the *moon*, (i. e. by the exceſs of her gravity towards the ſun, above her gravity towards the earth,) then the *moon* would, indeed, abandon the earth. For, in that caſe, the *moon* having leſs velocity than would be neceſſary to prevent her from deſcending within that circle, ſhe would approach to the ſun, and recede from the earth. But though the abſolute velocity of the *moon*, at the conjunction, be leſs than the velocity of the earth in the annual orbit, yet her gravity towards the ſun is ſo much diminiſhed, by her gravity toward the earth, that her abſolute velocity is ſtill much ſuperior to that which is requiſite to carry a body in a circle, there, about the ſun, that is acted on by the remaining force only. Therefore, from the moment of the conjunction, the *moon* is carried without ſuch a circle, receding continually from the ſun to greater and greater diſtances, till ſhe arrives at the oppoſition; where being acted on by the ſum of thoſe two gravities, and her velocity being now leſs than what is requiſite to carry a body in a circle, there, about the ſun, that is acted on by a force equal to that ſum, the *moon* thence begins to approach to the ſun again. Thus, ſhe recedes from the ſun, and approaches to it by turns, and in every month her path hath two apſides, a perihelion at the conjunction, and an aphelion at the oppoſition; between which ſhe is always carried in a manner ſimilar to that in which the primary planets revolve between their apſides. The planet recedes from the ſun at the perihelion, becauſe its velocity, there, is greater than that with which a circle could be deſcribed about the ſun, at the ſame diſtance, by the ſame centripetal force; and approaches towards the ſun from the aphelion, becauſe its velocity, there, is leſs than is requiſite to carry it in a circle, at that diſtance, about the ſun.

If we ſuppoſe the earth to revolve in a circular orbit round the ſun as its center, and the *moon* to revolve round the earth in the ſame manner; the planes of their orbits to coincide; the diameters of their orbits to be as 340 to 1; and the *moon* to perform 13,368 revolutions to every ſingle revolution of the earth; it is eaſy to inveſtigate the nature and deſcription of the curve generated by the center of the *moon*; and to determine whether this curve, in one lunation, be any-where convex towards the ſun.

Let S (*Tab.* III. *Analyſis*, *fig.* 69.) repreſent the ſun, E the earth; E*a* an arch of the orbit of the earth paſſed over by its center, in one lunation of the *moon*; the circumference of the circle E A F = the concentric arch A *a*: then, (becauſe 13 368 − 1 = 12.368 = the number of lunations in the year, or one revolution of the earth, and therefore S A : E A :: 12.368 : 1,) when the *moon* is in conjunction with the ſun, the diſtance between the ſun and *moon* will be greater than the diſtance or radius S A. Now the curve, deſcribed by the center of the *moon*, is the ſame as that deſcribed by a point M (E M being the ſemidiameter of the *moon*'s orbit), carried round by the rotation of the circle E A F on the arch A *a*: it is therefore of the cycloidal kind, having a point of inflexion, if every cycloid, deſcribed by a point within the generating circle, is inflected, as well upon a circular as upon a rectilineal baſe. To determine which,

Put S A or S R = *a*, E A or *e* R = *b*, E M or *e m* = *c*, R *m* = *r*, R *d* = *z*; and let *m* C be the radius of curvature at any point *m*, which, it is evident, muſt paſs through the point of contact R. Suppoſe the point *n* indefinitely near to *m*: then, R *r* and R *r* being the indefinitely ſmall contemporary arches with *m n*, and, conſequently, the triangles R *m r* and R *n r* equal in all reſpects; if we conſider the ſaid little arches R *r* and R *r* as little right lines perpendicular to the radii *e r* and S *r*, we ſhall have the ∠ *m* R *s* = ∠ *r* R *r* = (becauſe the angles *e* R *r* and S R *r*, added to either ſide of the equation, make it two right angles) ∠ R *e r* + ∠ R S *r*. Now, S R : *e* R :: ∠ R *e r* : ∠ R S *r*, and S R : S R + *e* R :: ∠ R *e r* : ∠ R *e r* + ∠ R S *r*, that is, $a : a+b :: \angle R\,e\,r : \angle m\,R\,n = \frac{a+b}{a} \angle R\,e\,r$.

Again, in any triangle, as *d m r*, if the angles *m d r*, *m r d*, and R *m r*, the complement of the obtuſe angle to two right angles, be indefinitely ſmall, they will be proportional to the oppoſite ſides *m r*, *m d*, and *d r*; that is, *d r* : *m d* :: ∠ R *m r* : ∠ *m r d*; and *d n* − *m d* : *d r* :: ∠ R *m r* − ∠ *m r d* : ∠ R *m r*, that is, *m* R : *d* R :: ∠ R *d r* : ∠ R *n r*, or, $r : z :: \frac{1}{2}\angle R\,e\,r : \angle R\,n\,r = \frac{z}{2r} \angle R\,e\,r$. And again, ∠ R C *n* : ∠ R *n* C :: R *n* : R C, that is, $\angle m\,R\,n - \angle R\,n\,r : \angle R\,n\,r :: R\,m : R\,C$, or, $\left(\frac{a+b}{a} - \frac{z}{2r}\right) \angle R\,r\,r : \frac{z}{2r} \angle R\,r\,r :: r : R\,C = \frac{ar z}{2ar + 2br - az}$.

Conſequently, $m\,R + R\,C = m\,C = \frac{2ar^2 + 2br^2}{2ar + 2br - az} = \frac{r^2}{r - \frac{az}{2a+2b}}$ = the radius of curvature at any point *m*.

Now, it is evident, that, at the point of inflection, the radius of curvature muſt be infinite; or that, on one ſide of the ſaid point, the expreſſion for the radius of curvature muſt be affirmative, and on the other negative; therefore, *r* muſt be more than $\frac{az}{2a+2b}$ on one ſide of the ſaid point, and on the other leſs; and conſequently, at the point of inflection, $r = \frac{az}{2a+2b}$; which, ſubſtituted for *r*, makes $(dm \times mR =) rz - r^2 = \frac{2nb^2 + a^2z^2}{2a+2b^2}$ = (becauſe $dm \times mR = fm \times ma =$) $b^2 - c^2$; from which equation we have $z = \frac{2a+2b\sqrt{b^2-c^2}}{\sqrt{2ab+a^2}}$. Or, to find *r*, ſay $2ar + 2br = az$, or $z = \frac{2ar+2br}{a}$; then, $(dm \times mR =) rz - r^2 = \frac{ar^2+2br^2}{a} = (fm \times ma =) b^2 - c^2$; which equation gives $r = \sqrt{\frac{ab^2-ac^2}{a+2b}}$, when the point *m* becomes a point of inflection.

Now, as *m* R (*r*) muſt, by the nature of the circle, always be greater than *m a*; that is, as $\sqrt{\frac{ab^2-ac^2}{a+2b}}$ muſt always be more than $b - c$; and conſequently, $\frac{ab^2-ac^2}{a+2b}$ be more than $\overline{b-c}^2$, that is, $\frac{ab+ac}{a+2b} \times \overline{b-c}$ be more than $\overline{b-c} \times \overline{b-c}$; therefore, *c* muſt always be more than $\frac{b^2}{a+b}$; that is, E M muſt be more than a third proportional to E S and E A, in order to have a point of inflection take place in the curve: but, in the preſent caſe, ES, EA, and EM, being as 13.368, 1, and $\frac{13.368}{340}$ or .039; therefore, EM is leſs than the ſaid third proportional; and conſequently, the curve M *m* *μ*, generated by the center of the *moon*, has not a point of inflection, or is no where convex towards the ſun. See Ferguſon's Aſtronomy, p. 120, &c. Maclaurin's Account of Sir Iſaac Newton's Phil. Diſc. book iv. ch. 5. p. 336, &c. 4to. Rowe's Fluxions, p. 127, &c.

MOON, *aſtronomy of the*. 1. To determine the period of the *moon*'s revolution round the earth, or the *periodical month*; and the time between one oppoſition and another, or the *ſynodical month*.

Since in the middle of a lunar eclipſe, the *moon* is oppoſite to the ſun, compute the time between two eclipſes, or oppoſitions, between which there is a great interval of time; and divide this by the number of lunations that have paſſed in the mean time; the quotient will be the quantity of the ſynodical month. Compute the ſun's mean motion, during the time of the ſynodical month, and add this to the entire circle deſcribed by the *moon*. Then, as the ſum is to 360°, ſo is the quantity of the ſynodical month to the periodical.

Thus, Copernicus, in the year 1500, November 6, at twelve at night, obſerved an eclipſe of the *moon* at Rome; and Auguſt 1, 1523, at 4h. 25′, another at Cracow: hence the quantity of the ſynodical month is thus determined:

Obſ. 2 An. 1523 d. 237 h. 4.25′
Obſ. 1 An. 1500 d. 310 h. 2.20′

Interval of time An. 22 d. 297 h. 2.5′
Add the intercalary days 5

Exact interval An. 22 d. 297 h. 2.5′
or 110910065′

Which divided by 282 months, elapſed in the mean time, gives the quantity of the ſynodical month 392211′, 9″, 9‴; that is, 29 days, 12 hours, 44 minutes.

From two other obſervations of eclipſes, the one at Cracow, the other at Babylon, the ſame author determines more accurately the quantity of the ſynodical month to be 392524′. 3″. 10‴. 9ⁱᵛ.

That is 29 d. 11h. 43′. 3″. 10‴.

The

The sun's mean motion in the time 29°. 6'. 24". 18"'.
The *moon's* motion . . . 389. 6. 24. 18.
Quantity of the periodical month 27 d. 7 h. 43'. 5".
Hence, 1. the quantity of the periodical month being given, by the rule of three we may find the *moon's* diurnal and horary motion, &c. And thus may tables of the mean motion of the *moon* be constructed.

2. If the sun's mean diurnal motion be subtracted from the *moon's* mean diurnal motion, the remainder will give the *moon's* diurnal motion from the sun: and thus may a table thereof be constructed.

3. Since, in the middle of a total eclipse, the *moon* is in the node, if the sun's place be found for that time, and to this be added six signs, the sum will give the *place of that node*.

4. From comparing the ancient observations with the modern, it appears, that the nodes have a motion, and that they proceed *in antecedentia*, i. e. from Taurus to Aries, from Aries to Pisces, &c. If, then, to the *moon's* mean diurnal motion be added the diurnal motion of the nodes, the same will be the motion of the *moon* from the node; and thence, by the rule of three may be found in what time the *moon* goes 360° from the dragon's head, or in what time the goes from, and returns to it: that is the quantity of the *draconitic month*.

5. If the motion of the apogee be subtracted from the mean motion of the *moon*, the remainder will be the *moon's* mean motion from the apogee; and thence, by the rule of three, is determined the quantity of the *anomalistic month*.

According to the observations of Kepler, the mean synodical month is 29 d. 12 h. 44' 3". 2"'. Her periodical month 27 d. 7 h. 43'. 8". The place of the apogee for the year 1700, January, 1, old style, was 11 S 8°. 57'. 1". The place of the ascending nodes 4 S 27°. 39'. 17". Mean diurnal motion of the *moon* 13°. 10'. 35". Diurnal motion of the apogee 6'. 41". Diurnal motion of the nodes 3'. 11". Lastly, the eccentricity 4362 parts, such, whereof the semidiameter of the eccentric is 100,000: and therefore the diurnal motion of the latitude is 13°. 13'. 46"; and the diurnal motion from the apogee 13°. 3'. 54".

To find the MOON'S *age or change.* The following canon, in which the twelve numbers answer to the twelve months, beginning with January, will serve for this purpose.

Janus 0, 2, 1, 2, 3, 4, 5, 6.
8, 8, 10, 10, these to the EPACT fix,
The sum, bate 30, to the month's day add,
Or take from 30, age or change is had.

The reason of adding these numbers to the epact in the several months, is because the lunar synodical months fall short of the calendar months; so that the epact, which expresses how much the lunar year falls short of the solar or calendar year, must be considered as continually increasing; and therefore to find the new *moons*, which are the beginnings of the synodical months, an addition must be made to the epact in every month, and more and more as the year advances; which additional numbers are called the menstrual epacts. Only nothing is to be added to the epact in January, because the annual epact, together with the day of the month, does then express the true age of the *moon*: but as January has 31 days, which is near 2 days more than a synodical month, therefore the beginning of the lunar months in February will fall near 2 days sooner than it did in January; consequently 2 is the menstrual epact of February; and then as February has but 28 or at most 29 days, which may be accounted one day less than a synodical month, the next lunar month will begin one day later in March than it did in February; consequently the menstrual epact of March decreases instead of increasing, and is but 1. If from thence you reckon the lunar months to consist of 30 days and 29 interchangeably, the new *moons* will fall so much earlier in the following months than the new *moons* did in January, as is expressed by the menstrual epacts in the canon, viz 2 days in April, 3 in May, &c. until they amount to 11 days at the end of the year, which are then added to the annual epact.

To find the time of the MOON'S *being in the meridian, or southing.* Multiply her age by 4; and divide the product by 5; the quotient gives the hour, and the remainder, multiplied by 12, the minute.

The reason of this rule is, that as the *moon* at the change comes to the south with the sun, or at twelve o'clock, and as there are thirty days, nearly, from one new *moon* to another, and twenty-four hours in a day; therefore she loses one day with another $\frac{4}{5}$, or $\frac{4}{5}$ of an hour in the time of her southing: now the *moon's* age, a number of days from the change being multiplied by 4, the product is so many fifths of an hour as she has lost, which divided by 5, is reduced to hours, and the remainder, if any, multiplied by 12, will be minutes.

To find the time of the MOON'S *beginning to shine.* Multiply her age, if under 15, by 48; and divide the product by 60: the quotient gives the hour; and the remainder the minute. If her age be above 15 days, subtract the time thus found, from 24; the remainder gives the time of shining in the morning.

MOON, *for the eclipses of the*, See ECLIPSES. *For the* MOON'S *parallax*, see PARALLAX.

Theory of the MOON'S *motions and irregularities.* The tables of equation, which serve to solve the irregularities of the sun, do likewise serve for those of the *moon*.

But then these equations must be corrected for the *moon*, otherwise they will not exhibit the true motions in the syzygies. The method is thus: Suppose the *moon's* place in the zodiac, required in longitude, for any given time; here, we first find, in the tables, the place where it would be, supposing its motion uniform, which we call *mean*, and which is sometimes faster, and sometimes slower, than the true motion: then, to find where the *true* motion will place her, which is also the *apparent*, we are to find in another table at what distance it is from its apogee; for, according to this distance, the difference between her true and mean motion, and the two places which correspond thereto, is the greater. The true place thus found, is not yet the *true* place; but varies from it, as the *moon* is more or less remote both from the sun, and the sun's apogee: which variation respecting, at the same time, those two different distances, they are to be both considered and combined together, as in a table apart. Which table gives the correction to be made of the true places first found. That place, thus corrected, is not yet the *true* place, unless the *moon* be either in conjunction, or opposition: if the be out of these, there must be another correction, which depends on two things taken together, and compared, viz. the distance of the *moon's* corrected place from the sun; and of that at which she is with regard to her own apogee; this last distance having been changed by the first correction.

By all these operations and corrections, we at length arrive at the *moon's true place* for that instant. In this, it must be owned, there occur prodigious difficulties: the lunar inequalities are so many, that it was in vain the astronomers laboured to bring them under any rule, before the great Sir Isaac Newton; to whom we are indebted both for the mechanical causes of these inequalities, and for the method of computing and ascertaining them: so that he has given us a world, in a great measure, of his own discovering, or rather subduing.

From the theory of gravity he shews, that the larger planets, revolving round the sun, may carry along with them smaller planets revolving round themselves; and shews also, *a priori*, that these smaller must move in ellipses having their umbilici in the centres of the larger; and must have their motion in their orbits variously disturbed by the motion of the sun; and, in a word, must be affected with those inequalities which we actually observe in the *moon*. And from this theory, he argues analogous irregularities in the satellites of Saturn.

From the same theory he examines the force which the sun has to disturb the *moon's* motion, determines the horary increase of the area which the *moon* would describe in a circular orbit by radii drawn to the earth—her distance from the earth—the horary motion in a circular and elliptic orbit—the mean motion of the nodes—the true motion of the nodes—the horary variation of the inclination of the *moon's* orbit to the plane of the ecliptic. Lastly, From the same theory he has found the annual equation of the *moon's* mean motion to arise from the various dilatation of her orbit; and that variation to arise from the sun's force, which being greater in the perigee, distends the orbit; and, being less in the apogee, suffers it to be again contracted. In the dilating orbit she moves more slowly; in the contracted, more swiftly: and the annual equation, whereby this inequality is compensated, in the apogee and perigee, is nothing at all; at a moderate distance from the sun, it amounts to 11' 50": and in other places it is proportional to the equation of the sun's centre, and is added to the mean motion of the *moon*, when the earth proceeds from its aphelion to its perihelion; and subtracted when in the opposite part.

Thus, supposing the radius of the *orbis magnus* 1000, and the earth's eccentricity 163; this equation, when greatest, according to the theory of gravity, comes out 11'. 49".

He adds, that in the earth's perihelion, the nodes move swifter than in the aphelion, and that in a triplicate ratio of the earth's distance from the sun, inversely. Whence arise annual equations of their motions, proportionable to that of the centre of the sun. Now the sun's motion in a duplicate ratio of the earth's distance from the sun inversely, and the greatest equation of the centre which this inequality occasions, is 1°, 56', 20", agreeable to

the sun's eccentricity 16½. If the sun's motion were in a triplicate ratio of its distance inversely, this inequality could generate the greatest equation 2°, 56′, 9″; and therefore the greatest equations which the inequalities of the motions of the *moon*'s apogee and nodes occasion, are to 2°, 56′, 9″, as the mean diurnal motion of the *moon*'s apogee, and the mean diurnal motion of her nodes, are to the mean diurnal motion of the sun. Whence the greatest equation of the mean motion of the apogee comes out 19′, 42″; and the greatest equation of the mean motion of the nodes 9′, 27″. The former equation is added, and the latter subtracted, when the earth proceeds from its perihelion to its aphelion, and the contrary in the opposite part of its orbit.

From the same theory of gravity, it also appears, that the sun's action on the *moon* must be somewhat greater when the transverse diameter of the lunar orbit passes through the sun, than when it is at right angles with the line that joins the earth and sun; and, therefore, that the lunar orbit is somewhat greater in the first case than in the second. Hence arises another equation of the mean lunar motion, depending on the situation of the *moon*'s apogee with regard to the sun, which is greatest when the *moon*'s apogee is in an octant with the sun; and none, when the arrives at the quadrature, or syzygies; and is added to the mean motion, in the passage of the *moon*'s apogee from the quadrature to the syzygies, and subtracted in the passage of the apogee from the syzygies to the quadrature.

This equation, which Sir Isaac calls *semestris*, when greatest, viz. in the octants of the apogee, arises to 3′, 45″, at a mean distance of the earth from the sun; but it increases and diminishes in a triplicate ratio of the sun's distance inversely; and therefore, in the sun's greatest distance, is 3′, 34″; in the smallest, 4′, 56″, nearly. But when the apogee of the *moon* is without the octants, it becomes less, and is to the greatest equation, as the sine of double the distance of the *moon*'s apogee from the next syzygy, to quadrature, to the radius.

From the same theory of gravity it follows, that the sun's action on the moon is somewhat greater when a right line, drawn through the *moon*'s nodes, passes through the sun, than when that line is at right angles with another joining the sun and earth: and hence arises another equation of the *moon*'s mean motion, which he calls *secunda semestris*, and which is greatest when the nodes are in the sun's octants, and vanishes when they are in the syzygies, or quadratures; and, in other situations of the nodes, is proportionable to the sine of double the distances of either node from the next syzygy, or quadrature.

It is added to the *moon*'s mean motion while the nodes are in their passage from the sun's quadratures to the next syzygy, and subtracted in their passage from the syzygies to the quadratures in the octants.

When it is greatest, it amounts to 47″, at a mean distance of the earth from the sun; as appears from the theory of gravity: at other distances of the sun, this equation in the octants of the nodes is reciprocally as the cube of the sun's distance from the earth; and therefore, in the sun's perigee is 45″; in his apogee nearly 49″.

By the same theory of gravity the *moon*'s apogee proceeds the fastest when either in conjunction with the sun, or in opposition to it; and is retrograde when in quadrature with the sun. In the former case, the eccentricity is greatest, and in the latter smallest. These inequalities are very considerable, and generate the principal equation of the apogee, which he calls *semestris*, or *semimenstrual*. The greatest *semimenstrual* equation is about 12°, 18′.

Horrox first observed the *moon* to revolve in an ellipsis round the earth placed in the lower umbilicus: and Halley placed the centre of the ellipsis in an epicycle, whose centre revolves uniformly about the earth: and from the motion in the epicycle arise the inequalities now observed in the progress and regress of the apogee, and the quantity of the eccentricity.

Suppose the mean distance of the *moon* from the earth divided into 100,000; and let T (*Tab. Astron. fig.* 17.) represent the earth, and TC the mean eccentricity of the *moon* 5505 parts; produce TC to B, that CB may be the sine of the greatest semimenstrual equation 12°, 18′, to the radius TC; the circle EDA, described on the centre C, with the interval CB, will be the epicycle wherein the centre of the lunar orb is placed, and wherein it revolves according to the order of the letters EDA. Take the angle ECD equal to double the annual argument, or double the distance of the true place of the sun from the *moon*'s apogee once equated, and CTD will be the semimenstrual equation of the *moon*'s apogee; and TD the eccentricity of its orbit tending to the apogee equated a second time. From hence the *moon*'s mean motion, apogee, and eccentricity, as also the greater axis of its orbit 200,000, the *moon*'s true place, as also her distance from the earth, are found, and that by the commonest methods.

In the earth's perihelion, by reason of the greater force of the sun, the centre of the *moon*'s orbit will move more swiftly about the centre C than in the aphelion, and that in a triplicate ratio of the earth's distance from the sun inversely. By reason of the equation of the centre of the sun, comprehended in the annual argument, the centre of the *moon*'s orbit will move more swiftly in the epicycle BDA, in a duplicate ratio of the distance of the earth from the sun inversely.

That the same may still move more swiftly in a simple ratio of the distance inversely from the centre of the orbit D, draw DE towards the *moon*'s apogee, or parallel to TC; and take the angle EDC equal to the excess of the annual argument, above the distance of the *moon*'s apogee from the sun's perigee in consequentia; or, which is the same thing, take the angle CDF equal to the complement of the true anomaly of the sun to 360°; and let DF be to DC as double the eccentricity of the *orbis magnus* to the mean distance of the sun from the earth, and the mean diurnal motion of the sun from the *moon*'s apogee, to the mean diurnal motion of the sun from its own apogee, conjunctly, i. e. as 33′ is to 1000, and 52′, 27″, 16‴, to 59′, 8″, 10‴, conjunctly; or as 3 to 160. Conceive the centre of the *moon*'s orbit placed in the point F, and to revolve in an epicycle, whose centre is D, and its radius DF, while the point D proceeds in the circumference of the circle DABD: thus the velocity, wherewith the centre of the *moon*'s orbit moves in a certain curve, described about the centre C, will be reciprocally as the cube of the sun's distance from the earth.

The computation of this motion is difficult; but it will be made easy by the following approximation: if the *moon*'s mean distance from the earth be 100,000 parts, and its eccentricity TC 5505 of those parts, the right line CB or CD will be found 1123; and the right line DF 33½. This right line, at the distance TC, subtends an angle to the earth, which the transferring of the centre of the orbit from the place D to F generates in the motion of this centre; and the same right line doubled, in a parallel situation, at the distance of the upper umbilicus of the *moon*'s orbit from the earth, subtends the same angle, generated by that translation in the motion of the umbilicus; and at the distance of the *moon* from the earth subtends an angle which the same translation generates in the motion of the *moon*; and which may therefore be called *the second equation of the centre*.

This equation of a mean distance of the *moon* from the earth, is as the sine of the angle contained between the right line DF, and a right line drawn from the point F to the *moon*, nearly; and when greatest, amounts to 2′, 25″. Now the angle comprehended between the right line DF and a line from the point D, is found either by subtracting the angle EDF from the mean anomaly of the *moon*, or by adding the *moon*'s distance from the sun to the distance of the *moon*'s apogee from the apogee of the sun. And as radius is to the sine of the angle thus found, so is 2′, 25″, to the second equation of the centre; which is to be added, if that line be less than a semicircle; and subtracted, if greater: thus we have its longitude in the very syzygies of the luminaries.

If a more accurate computation be required, the *moon*'s place thus found must be corrected by a second variation. The first and principal variation we have already considered, and have observed it to be greatest in the octants. The second is greatest in the quadrants, and arises from the different action of the sun on the *moon*'s orbit, according to the different position of the *moon*'s apogee to the sun, and is thus computed; as radius is to the versed sine of the distance of the *moon*'s apogee from the sun's perigee, in consequentia, so is a certain angle P to a fourth proportional. And as radius is to the sine of the *moon*'s distance from the sun, so is the sum of this fourth proportional and another angle Q to the second variation; which is to be subtracted, if the *moon*'s light be increasing; and added, if diminishing.

Thus we have the *moon*'s true place in her orbit; and by reduction of this place to the ecliptic, we have the *moon*'s longitude. The angles P and Q are to be determined by observation: in the mean time, if for P be assumed 2′, and for Q 1′, we shall be near the truth.

MOON, *nature and properties of the*. I. From the various phases of the *moon*: from her only shewing a little part illumined, when following the sun nearly to set; from that part's increasing as she recedes from the sun, till at the distance of 180° she shines with a full face; and again wanes as she re-approaches that luminary, and loses all her light when she meets him: from the lucid part's being constantly turned towards the west, while the moon increases; and towards the east when she decreases: it is evident, that only that part turned on which the sun's rays fall. And from the phenomena of eclipses,

happening when the *moon* ſhould ſhine with a full face; viz. when ſhe is 180° diſtant from the ſun; and the darkened parts appearing the ſame in all places; it is evident ſhe has no light of her own, but borrows whatever light ſhe has from the ſun: for if ſhe did, being globular, we ſhould always ſee her with a round full orb like the ſun.

2. The *moon* ſometimes diſappears in a clear heaven, ſo as not to be diſcoverable by the beſt glaſſes; little ſtars of the fifth and ſixth magnitude all the time remaining viſible. This phenomenon Kepler obſerved twice anno 1580, and 1584, and Herelius in 1620. Riccioius, and other Jeſuits at Bologna, and many people throughout Holland, obſerved the like April 14, 1642, yet at Venice and Vienna ſhe was all the time conſpicuous. December 23, 1707, there was another total obſcuration. At Arles the firſt appeared of a yellowiſh brown; at Avignon ruddy and tranſparent, as if the ſun had ſhone through it at Marſeilles, one part was reddiſh, the other very duſky; and, at length, though in a clear ſky, ſhe wholly diſappeared. Here it is evident, that the colours appearing different at the ſame time, do not belong to the *moon*; but they are probably occaſioned by our atmoſphere, which is variouſly diſpoſed at different times, for reflecting of thoſe or thoſe coloured rays.

3. The eye, either naked, or armed with a teleſcope, ſees ſome parts in the *moon*'s face darker than others, which are called *maculæ*, or *ſpots*. Through the teleſcope, while the *moon* is either increaſing or decreaſing, the illuminated parts in the maculæ appear evenly terminated; but in the bright parts, the boundary of the light appears jagged and uneven, compoſed of diſſimilar arches, convex and concave. (See *Tab. Aſtron. fig.* 18.) There are alſo obſerved lucid parts diſperſed among the darker; and illuminated parts are ſeen beyond the limits of illumination; other intermediate ones remaining ſtill in darkneſs; and near the maculæ, and even in them, are frequently ſeen ſuch lucid ſpecks. Beſide the maculæ obſerved by the ancients, there are other variable ones inviſible to the naked eye, called *new maculæ*, always oppoſite to the ſun; and which are hence found among thoſe parts which are the ſooneſt illumined in the increaſing *moon*, and in the decreaſing *moon* loſe their light later than the intermediate ones; running round, and appearing ſometimes longer, ſometimes ſmaller.

Hence, 1. As all parts are equally illumined by the ſun, inaſmuch as they are equally diſtant from him; if ſome appear brighter, and others darker; ſome reflect the ſun's rays more copiouſly than others; and therefore they are of *different natures*. And, 2. Since the boundary of the illumined part is very ſmooth and equable in the maculæ, their ſurface muſt be ſo too. 3. The parts illumined by the ſun ſooner, and deſerted later, than others that are nearer, are higher than the reſt; i. e. they ſtand upabove the other ſurface of the *moon*. 4. The new maculæ anſwer perfectly to the ſhadows of terreſtrial bodies.

4. Hevelius writes, that he has ſeveral times found, in then perfectly clear, when even ſtars of the ſixth and ſeventh magnitude were conſpicuous, that at the ſame altitude of the *moon*, and the ſame elongation from the earth, and with one and the ſame excellent teleſcope, the *moon* and its maculæ ſeemed equally lucid, clear, and perſpicuous, at all times; but are much brighter, purer, and more diſtinct, at one time than another. From the circumſtances of the obſervation, it is evident, the reaſon of this phenomenon is not either in our air, in the tube, in the *moon*, or in the ſpectator's eye; but it muſt be ſought for in ſomething exiſting about the *moon*.

5. Caſſini frequently obſerved Saturn, Jupiter, and the fixed ſtars, when hid by the *moon*, near her limb, whether the illumined or dark one, to have their circular figure changed into an oval one; and in other occultations he found no alteration of figure at all. In like manner, the ſun and *moon* riſing and ſetting in a vaporous horizon, do not appear circular, but elliptical.

Hence, as we know, by ſure experience, that the circular figure of the ſun and *moon* is only changed into an elliptical one by means of the refraction in the vapoury atmoſphere; ſome have concluded, that at the time when the circular figure of the ſtars is thus changed by the *moon*, there is a denſe matter encompaſſing the *moon*, wherein the rays, emitted from the ſtars, are refracted; and that, at other times, when there is no change of figure, this matter is wanting.

This phenomenon is well illuſtrated by the following experiment.

To the inner bottom of any veſſel, either plane, convex, or concave, with wax faſten a circle of paper; then pouring in water, that the rays, reflected from the circle in the air, may be refracted before they reach the eye: viewing the circle obliquely, the circular figure will appear changed into an ellipſis.

6. The *moon*, then, is a denſe opake body, furniſhed with mountains and valleys. That the *moon* is denſe, and impervious to the light, has been ſhewn; but ſome parts ſink below, and others riſe above the ſurface; and that conſiderably, inaſmuch as they are viſible at ſo great a diſtance as that of the earth from the ſun: in the *moon*, therefore, are huge mountains, and very deep valleys. Riccioius meaſured the height of one of the mountains, called St. Catharine, and found it nine miles high.

Moon, to meaſure the heights of the mountains of the. Suppoſe ED (*fig.* 19.) the *moon*'s diameter, ECD the boundary of light and darkneſs; and A the top of a hill in the dark part beginning to be illumined: with a teleſcope obſerve the proportion of AE, or the diſtance of A from the line where the light commences to the diameter ED: here we have two ſides of a rectangled triangle AE, CE; the ſquares of which added together give the ſquare of the third; whence the ſemi-diameter CA being ſubtracted, leaves AB, the height of the mountain.

Riccioius, v. gr. found the top of the mount St. Catharine illumined at the diſtance of $\frac{1}{15}$ of the *moon*'s diameter from the confines of light. Suppoſing, therefore, CE 8, and AE 1, the ſquares of the two will be 65, whoſe root is 8.062 the length of AC: ſubtracting therefore BC = 8, the remainder is AB = 0.062. The *moon*'s ſemidiameter, therefore, is to the mountain's height as 8 is to 0.062; i. e. as 8000 to 62. Suppoſing, therefore, the ſemidiameter of the *moon* 1162 Engliſh miles, by the rule of three we find the height of the mountain 9 miles.

The heights, &c. of the lunar mountains being meaſurable, aſtronomers have taken occaſion to give each its name. Riccioius, whom moſt others now follow, diſtinguiſhed them by the names of celebrated aſtronomers; and by theſe names they are ſtill expreſſed in obſervations of the lunar eclipſes, &c. See the figure, *Tab. Aſtron. fig.* 20.

Aſtronomers are now generally of opinion, that the *moon* has no atmoſphere of any viſible denſity ſurrounding her, as we have: for if ſhe had, we could never ſee her edge ſo well defined as it appears: but there would be a ſort of miſt or hazineſs round her, which would make the ſtars look fainter, when they are ſeen through it. But obſervation proves, that the ſtars which diſappear behind the *moon* retain their full luſtre until they come to touch her very edge, and then they vaniſh in a moment. This has been often obſerved by aſtronomers, but particularly by Caſſini, of the ſtar γ in the breaſt of Virgo, which appears ſingle and round to the bare eye; but through a refracting teleſcope of fifteen feet, appears to be two ſtars ſo near together, that the diſtance between them ſeems to be but equal to one of their apparent diameters. The *moon* was obſerved to paſs over them on the 21ſt of April, 1705, N. S. and as her dark edge drew near to them, it cauſed no change in their colour or ſituation. At 25 min. 14 ſec. paſt twelve at night, the moſt weſterly of theſe ſtars was hid by the dark edge of the *moon*; and in 30 ſeconds afterward, the moſt eaſterly ſtar was hid: each of them diſappearing behind the *moon* in an inſtant, without any preceding diminution of magnitude or brightneſs; which by no means could have been the caſe if there were an atmoſphere round the *moon*: for then, one of the ſtars falling obliquely into it before the other, might by refraction to have ſuffered ſome change in its colour, or in its diſtance from the other ſtar which was not yet entered into the atmoſphere. But no ſuch alteration could be perceived, though the obſervation was performed with the utmoſt attention to that particular; and was very proper to have made ſuch a diſcovery. The faint light, which has been ſeen all around the *moon*, in total eclipſes of the ſun, has been obſerved, during the time of darkneſs, to have its centre coincident with the centre of the ſun; and was therefore much more likely to ariſe from the atmoſphere of the ſun, than from that of the *moon*; for if it had been owing to the latter, its centre would have gone along with the *moon*'s.

If there were ſeas in the *moon*, ſhe could have no clouds, rains, nor ſtorms, as we have; becauſe ſhe has no ſuch atmoſphere to ſupport the vapours which occaſion them. And every one knows, that when the *moon* is above our horizon in the night-time, ſhe is viſible, unleſs the clouds of our atmoſphere hide her from our view; and all parts of her appear conſtantly with the ſame clear, ſerene, and calm aſpect. But thoſe dark parts of the *moon*, which were formerly thought to be ſeas, are now found to be only vaſt deep cavities, and places which reflect not the ſun's light ſo ſtrongly as others, having many caverns and pits whoſe ſhadows fall within them, and are always dark on the ſides next the ſun; which demonſtrates their being hollow: and moſt of theſe pits have little knobs like

hillocks

hillocks standing within them, and casting shadows also; which cause these places to appear darker than others which have fewer, or less remarkable caverns. All these appearances shew that there are no seas in the *moon*; for if there were any, their surfaces would appear smooth and even, like those on the earth.

There being no atmosphere about the *moon*, the heavens in the day time have the appearance of night to a lunarian who turns his back towards the sun; and when he does, the stars appear as bright to him as they do to us the night to us. For it is entirely owing to our atmosphere that the heavens are bright about us in the day.

MOON, *as to the influence of the*, on the changes of our weather, and the constitution of the human body, we shall observe that the vulgar doctrine concerning it is very ancient, and has gained credit among the learned, without sufficient examination; but it is now generally exploded by philosophers, as equally destitute of all foundation in physical theory, and unsupported by any plausible analogy.

The common opinion is, that the lunar influence is exerted at the syzygies and quadratures, and for three days before and after each of those epochs. There are twenty-four days, therefore, in each synodic month, over which the *moon* at this rate is supposed to preside, and as the whole consists but of 29 days, 12½ hours, only 5¼ days, are exempt from her pretended dominion. Hence, though the changes of the weather should happen to have no connection whatever with the *moon's* aspects, and they should be distributed in an equal proportion through the whole synodic month; yet any one who shall predict, that a change shall happen on some one of the twenty-four days assigned, rather than in any of the remaining 5¼, will always have the chances 24 to 5¼ in his favour. Men may, therefore, easily deceive themselves, especially in so unsettled a climate as our's. Moreover, the writers who treat of the signs of the weather, derive their prognostics from circumstances, which neither argue any real influence of the *moon* as a cause, nor any belief of such an influence, but are merely indications of the state of the air at the time of observation: such are, the shape of the horns, the degree and colour of the light, and the number and quality of the luminous circles which sometimes surround the *moon*, and the circumstances attending their disappearance. See the *Diosemeia* of Aratus, and the Scholia of Theon. The vulgar soon began to consider these things as causes, which had been proposed to them only as signs: and the notion of the *moon's* influence on all terrestrial things was confirmed by her manifest effect upon the ocean. See on this subject, Phil. Trans. vol. lxv. part 2. p. 178, &c.

The famous Dr. Mead was a believer in the influence of the sun and *moon* on the human body, and published a book to this purpose, intitled, De Imperio Solis ac Lunæ in Corpore humano: but this opinion has been exploded by philosophers, as equally unreasonable in itself, and contrary to fact. As the most accurate and sensible barometer is not affected by the various positions of the *moon*, it is not likely that the human body should be affected by them. See LUNATIC.

MOON, *harvest*. It is remarkable, that the *moon*, during the week in which she is full in harvest, rises sooner after sun-setting than she does in any other full *moon* week in the year. By doing so, she affords an immediate supply of light after sun-set, which is very beneficial to the farmers for reaping and gathering in the fruits of the earth: and therefore they distinguish *this* full *moon* from all the others in the year, by calling it the *harvest-moon*.

Mr. Ferguson has given a full account of the *harvest-moon* in his Astronomy; the substance of which is as follows, in a problem on the common celestial globe.

Make chalk-marks all round the globe, on the ecliptic, at 12½ degrees from each other (beginning at Capricorn) which is equal to the *moon's* daily mean motion from the sun; then elevate the north pole of the globe to the latitude of any place in Europe; suppose London, whose latitude is 51½ degrees north.

This done, turn the ball of the globe round, westward, in the frame thereof; and you will see that different parts of the ecliptic make very different angles with the horizon, as these parts rise in the east: and therefore, in equal times, very unequal portions of the ecliptic will rise. About Pisces and Aries, seven of these chalk-marks will rise in little more than two hours, as measured by the motion of the index on the horary circle: but, about the opposite signs, Virgo and Libra, the index will go over eight hours in the time that seven marks will rise. The intermediate signs will more or less partake of these differences as they are more or less remote from those above mentioned.

Hence it is plain, that when the *moon* is in Pisces and Aries, the difference of her rising will be little more than two hours in seven days; but in Virgo and Libra it will be eight hours in seven days: and this happens every month of the year, because the *moon* goes through all the signs of the ecliptic in a month, or rather in 27 days, 8 hours.

The *moon* is always opposite to the sun when she is full, and the sun is never in Virgo and Libra but in our harvest months; and therefore, the *moon* is never full in Pisces and Aries (which are the signs opposite to Virgo and Libra) but in our harvest months. Consequently, when the *moon* is about her full in harvest, she rises with less difference of time, or more immediately after sun-set, than when she is full in any other month of the year.

In our winter, the *moon* is in Pisces and Aries about the time of her first quarter, and rises about noon; but her rising is not then taken notice of, because the sun is above the horizon.

In spring, *the moon* is in Pisces and Aries about the time of her change; and then, as she gives no light, and rises with the sun, her rising cannot be perceived.

In summer, the *moon* is in Pisces and Aries about the time of her last quarter; and then, as she is on the decrease, and rises not till midnight, her rising generally passes unobserved.

But in harvest, the *moon* is full in Pisces and Aries (these signs being opposite to the sun in our autumnal months) and rises soon after sun-set for several evenings successively; which makes her regular rising very conspicuous at that time of the year, as it is so beneficial then to the farmers, in affording them an immediate supply of light after the going down of the sun.

This would always be the case if the *moon's* orbit lay in the plane of the ecliptic. But as the *moon* moves in an orbit which makes an angle of 5 degrees 18 minutes with the ecliptic, and crosses it only in the two opposite points called the nodes, her rising when in Pisces and Aries, will sometimes not differ above an hour and forty minutes through the whole of seven days; and at other times, in the same two signs, she will differ three hours and a half in the time of her rising in a week, according to the different positions of the nodes with respect to these signs; which positions are constantly changing, because the nodes go backward through the whole ecliptic in 18 years and 225 days.

This revolution of the nodes will cause the *harvest moons* to go through a whole course of the most and least beneficial states with respect to the farmers every nineteen years. The following table shews in what years the *harvest moons* are least beneficial as to the times of their rising, and in what years most, from 1751 to 1861. The columns of years under the letter L, are those in which the *harvest moons* are least of all beneficial, because they fall about the descending node; and those under M are the most of all beneficial, because they fall about the ascending node. In all the columns from N to S, the *harvest moons* gradually descend in the lunar orbit, and rise to less heights above the horizon. From S to N, they ascend in the like proportion, and rise to greater heights above the horizon. In both the columns under S, the *harvest moons* are in the lowest part of the *moon's* orbit, that is, farthest south of the ecliptic; and in the columns under N, the reverse. And in both these cases, their rising, though not at the same times, are nearly the same with regard to the difference of time, as if the *moon's* orbit were coincident with the ecliptic.

Years in which the *harvest moons* are least beneficial.

1854	1854	1855	1856	1857	1858	1859	1860	1861	

We may observe farther, that in summer, with us the full *moons* are low, and their stay is short above the horizon, when the nights are short and we have the least occasion for *moon*-light: in winter they go high, and stay long above the horizon, when the nights are long, and we want the greatest quantity of *moon*-light. Moreover, as the sun is above the horizon of the north pole from the 20th of March till the 23d of September, it is plain that the *moon*, when full, being opposite to the sun, must be below the horizon during that half of the year. But when

when the sun is in the southern half of the ecliptic, he never rises to the north pole, during which half of the year, every full *moon* happens in some part of the northern half of the ecliptic, which never sets. Consequently, as the polar inhabitants never see the full *moon* in summer, they have her always in the winter, before, at, and after the full, shining for fourteen of our days and nights. And when the sun is at his greatest depression below the horizon, being then in Capricorn, the *moon* is at her first quarter in Aries, full in Cancer, and at her third quarter in Libra. And as the beginning of Aries is the rising point of the ecliptic, Cancer the highest, and Libra the setting point, the *moon* rises at her first quarter in Aries; is most elevated above the horizon, and full, in Cancer; and sets at the beginning of Libra in her third quarter, having continued visible for fourteen diurnal rotations of the earth. Thus the poles are supplied one half of the winter time with constant *moon*-light in the sun's absence; and only lose sight of the *moon* from her third to her first quarter, while the gives but very little light, and could be but of little, and sometimes of no service to them.

To find the true time of new and full moon. For this purpose, Mr. Ferguson has calculated and given us the following tables; by which the method of operation is perhaps the shortest and easiest extant.

For any proposed year, within the limits of table I. write out the mean time of new or full *moon* in January, with its arguments for the two equations under A and B. With these arguments find the correspondent equations in table III. and IV. which add to the above mean time, and you will have the true time of new or full *moon* in January.

For the time of new or full *moon* in any month after January, to the mean time in that month add as many lunations from table II. as the given month is after January; and to the arguments A and B for January, add those under A and B belonging to the number of lunations taken out. With the sum of all these arguments, if not more than 360, find the correspondent equations in table III. and IV. which equations being added to the mean time, will give the true time of the required new or full *moon*, near enough for any almanack. When the sum of the arguments under A or B exceeds 360, subtract 360 from it; and with the remainder enter the corresponding table, and take out the equation.

N. B. If the number of months (thus taken out) after January, be equal to, or exceed the number of days accounted from the beginning of January on which the new or full *moon* falls, in that month, you must take out one lunation more from table II. than what answers to the number of months after January; otherwise you will not have the time of the required new or full *moon*, but of that which is next before it.

Lastly, with the number of days (arising from the lunations added to the time in January) enter table V. under the given month; and, against *that* number, look in the left hand column, under *days*, and you will have the day of the month on which the required new or full *moon* falls.

N. B. In leap years, in the months of January and February, to have the new or full *moon* on the day wherein it really falls, add a day to the time found by the tables.

EXAMPLE I. *Required the true time of new* moon *in January*, 1772?

	D.	H.	M.	A	B
A. D. 1772, (tab. I. for Jan.) new *moon*	3	6	9	185	298
In tab. III. (A) against 185 is the equation	0	4	33		
In tab. IV. (B) against 298 is the equation	0	0	52		
These added together give the true time, viz. January	3	11	34	Add 1 day.	

So the true time (1772 being a leap year) is January 4th, at 34 minutes past 11 o'clock at night; the time being always reckoned from noon.

EXAMPLE II. *Required the true time of new* moon, in *July*, 1772.

	D.	H.	M.	A.	B.
A. D. 1772, mean new *moon* in Jan.	3	6	9	185	298
Add 7 lunations from tab. II.	206	17	8	204	181
The sums are	209	23	17	389	479
In table III. (A) against 29 is		2	12	360	360
In table IV. (B) against 119 is		18	3	29	119
The whole sum amounts to	210	19	32		

Then, in table V. under July, against 210 is 29 in the left hand column: so that the true time is the 29th of July, at 19 hours 32 minutes past noon; which, in common reckoning, is the 30th of July, at 32 minutes past seven in the morning.

EXAMPLE III. *Required the true time of full* moon *in July*, 1770?

	D.	H.	M.	A.	B.
A.D. 1770, mean full *moon* in Jan.	10	18	5	192	205
Add 6 lunations from table II.	177	4	24	175	155
The sums are	187	22	33	367	360
In table III. (A) against 7 is		3	42	0	0
In table IV. (B) against 360 is		9	48	7	
The whole amounts to	188	12	3		

Then, in table V. under July, against 188, is 7 in the left hand column: so that the true time is the 7th of July, at three minutes past twelve o'clock at night.

The times found by these tables never differ above twenty minutes from the truth, and it is very seldom the error is half so much. The calculation is made in less than a twentieth part of the time that it could be done from Flamsteed's Tables.

TABLE I.

The mean times of new and full *moon* in January.

MOON, *acceleration of the*. See ACCELERATION.

MOON-*dial*. See DIAL.

MOON, *horizontal*. See *Apparent* MAGNITUDE.

MOON, *prime of the*. See PRIME.

MOON-*eyes*, in the *Manege*. A horse is faid to have *moon-eyes* when the weakneſs of his eyes increaſes or decreaſes according to the courſe of the *moon*; ſo that in the wane of the *moon* his eyes are muddy and troubled, and at new *moon* they clear up; but ſtill he is in danger of loſing his eye-ſight quite.

MOON-*fiſh*, a name given to the fiſh called by authors ORBIS.

MOON-*ſeed*, *menifpermum*, in *Botany*, a genus of the *dioecia dodecandria* claſs. Its characters are theſe: they are male and female in different plants; the male flowers have four exterior and eight interior petals, and fixteen ſtamina; the female have eight barren ſtamina, and double ſingle-ſeeded berries. Linnæus reckons eight ſpecies.

MOON *trefoil*, in *Botany*. See *Snail* TREFOIL.

MOON-*wort*, in *Botany*. See HONESTY.

MOOR, *mor*, a word ſometimes uſed to expreſs a heath, or barren tract of ground.

The word is ſometimes alſo uſed for a *morafs*, *muſh*, or *fen*.

Mera

Moro masse, in *Ancient Writings*, particularly denotes a mass, or peat mass.

MOOR-*berry*, in *Botany*. See WHORTLE-*berry*.

MOOR-*hazard*. See HAZZARD.

MOOR-*cock*, an English name for the red game, or lagopus, more commonly called the gor-cock. It is a very delicate bird, larger than a partridge, and common on the hills in Derbyshire and Yorkshire. See GOR-*cock*.

MOOR-*hens*, in *Ornithology*, is according to some authors, the name of a genus of water-birds. See GALLINULA.

The common *moor-hen*, called *gallinula aquatica* by authors, and by Linnæus *fulica coerulea*, is a very well known bird, somewhat like the coot in shape, but smaller, and very much differing from the body; the crown of the head, hind part of the neck, the back, and coverts of the wings, are of a fine, but very deep olive green; its feet are greenish, and its breast a lead-coloured blue; its belly greyish; the colours of the plumage in the female are much less brilliant than those of the male; and it is inferior in size. This bird is common about our rivers, breeds twice or thrice in the summer, strikes with the bill like a hen, and in the spring has a shrill call; and is a very well-shaped bird.

MOOR-*land*, or *Moor-ground*, in *Agriculture*, is a black, light, and soft earth, very loose, and without any admixture of stones, and with very little clay, or sand.

The uppermost stratum of the fen-lands is usually of this earth, and it commonly constitutes a moderately thick or deep bed. Intermixed with water it cannot easily be worked up into a paste; and when with labour worked up into somewhat of a firm mass, its surface appears spungy and porous; and as soon as dry, it easily moulders away to powder.

It is usually soft to the touch, unless it be worked very closely between the fingers, then it shews a mixture of a small quantity of sand, both to the touch and to the eye. It seems indeed to consist almost entirely of pure vegetable matter, and this lying in such plenty on the surface of the fen-lands is the cause of their being so very fertile.

The great disadvantage of the places which have this soil, is their being liable to be glutted with wet; and to remedy the inconveniencies arising from thence, the farmers who rent these lands have a custom of burning the soil at proper seasons. It burns very freely and easily, the surface readily catching flame, and a substance somewhat bituminous, usually contained among the soil, helps the burning.

MOOR-*stone*, the name of a very remarkable stone found in Cornwall, and some other parts of England, and used in the coarser works of the present builders.

This is truly a white granite, and is a very valuable stone. It is a very coarse and rude, but beautiful congeries of variously constructed and differently figured particles, not diffused among, or running into one another, but each pure and distinct, though firmly cohering with whatever it comes in contact with. Its colours are principally black and white; the white are of a soft, marbly texture, and opake, formed into large congeries, and containing a sort of tabulated structure; among these there are many of a pure crystalline splendor and transparence; and in some are lodged in different directions many small flaky masses of pure talcs of several colours; some are wholly pellucid, others of an opake white, others of the colour of brown crystal, and a vast number perfectly black. It is found in immense strata in some parts of Ireland, but is differgarded there.

It is found with us in Devonshire, Cornwall, and some other counties; and brought thence in vast quantities to London. It never forms any whole strata there, but is found on the surface of the earth in immense and unmanageable masses; and to separate these into portable ones, they dig a hole with a wedge in some part of them, and surrounding it with a ridge of clay they fill it up with water; this by degrees soaks in, and finding its way into the imperceptible cracks, so far loosens the cohesions of the particles there, that the day after they drive a larger wedge into the hole, and the stone breaks into two or more pieces. It is used in London for the steps of public buildings; and on other occasions, where great strength and hardness are required.

The people of Cornwall, who have this stone in great plenty, use it in their tin-works, and particularly in their tin-kiln, on the good effect of which a great deal depends. This kiln is four-square, and at its top is placed a large block of *moor-stone*; the usual size of this block is six feet in length, and four in breadth; in the middle of this block there is made a hole of about six inches in diameter. This stone serves as a head to cover another like stone placed beneath it; but this under one is not so long as the upper by six inches. The reason of this is, that it must not reach the innermost or back part of the wall, which is the open place through which the flame ascends from another place below that, where a very strong fire of furze is constantly kept up; and there is another little hole also on the outside. The fore-part is like a common oven, and has such a sort of chimney.

The tin-ore is roasted in this kiln, to burn away the mundic, in this manner: the ore is brought in powder, and poured out in heaps on the surface of the top-stone; a man stands there and thrusts it down through the hole in this stone into the kiln, that is, to the surface of the under-stone; a person who stands below spreads this as it falls with an iron rake, and gives notice to the person above when there is enough down, that is when the surface of the lower stone is covered three or four inches thick. When this is done, the hole at the top is covered with green furze, that the flame may reverberate the stronger; and the heat that the *moor-stone* acquires helps to roast the ore: while the flame that comes up from the ore is blue, there yet remains mundic among it; but when this is burnt off, the flame is yellow. Phil. Trans. N° 69.

The miners in some parts of Cornwall use the name *moor-stone* for a sort of coarse free-stone, which lies very often over the tin-ore; this is of a greyish colour, and is somewhat softer than that usually employed in building. See GROWAN.

MOOR-*stitching*, a common English name for the œnanthe, more frequently called the CROSS-*chaster*.

MOORING, at *Sea*, is the act of confining and securing a ship in a particular station, by chains or cables, which are either fastened to the adjacent shore, or to anchors in the bottom.

To MOOR *across*, is to lay out one of the anchors on one side.

To MOOR *alongst*, is to have an anchor in a river, and a hawser on shore.

To MOOR *quarter fast*, is to moor quartering, between the two first ways.

MOORING *for east, west*, &c. is when they observe which way, and on what point of the compass the wind or sea is most likely to endanger the ship, and there lay out an anchor.

MOORING *a fair birth*, at *Sea*, is *mooring* in a place free from any annoyance.

MOORING *a-precife*, at *Sea*, is to have an anchor out, and a hawser athore; then the ship is *moored* with her head athore: and two cables are the least, and four the best to *moor* by. See ANCHOR.

MOORING *water-fast*, is to *moor* neither alongst nor athwart the tide, but quartering between both.

MOORINGS, in *Sea-Language*, are usually an assemblage of anchors, chains, and bridles, laid athwart the bottom of a river, or haven, to ride the shipping contained therein. The anchors, employed on this occasion, have rarely more than one fluke, which is sunk in the river near low-water mark. Two anchors, being fixed in this manner, in the opposite side of the river, are furnished with a chain extending across from one to the other. In the middle of the chain is a large square link, whose lower end terminates in a swivel, which turns round in the chain as about an axis, whenever the ship veers about with the change of the tide. To this swivel-link are attached the bridles, which are short pieces of cable, well served, whose upper ends are drawn into the ship, at the *mooring* ports, and afterwards fastened to the masts, or cable-bolts. A great number of *moorings* of this sort are fixed in the harbours adjacent to the king's dock-yards, as Deptford, Chatham, Portsmouth, Plymouth, &c. Falconer.

MOORS, in the Isle of Man, those who summon the courts for the several *sheadings*; such are the lord's bailiffs. Every *moor* has the like office with our bailiff of the hundred.

MOOR-*head*, in *Chemistry*, a copper cap made in form of a head, to be set over any vessel, or over a reverberating furnace.

MOOR-*head* also denotes the head of a copper or glass still or alembic, which is fitted on to the body or cucurbit, and hath a beak or pipe to let the spirit run down into the receiver.

MOOR-*hoard*, in the *Mystery*. See MOOR-*head*.

MOOSE-*deer*. The first mention we find of this remarkable animal, is in a tract of Mr. Josselyn's, entitled, New England Rarities. That author says, it is a very fine creature, growing to twelve feet high; the horns are extremely beautiful, with broad palms, some of those full grown being two fathom from the tip of one horn to the tip of the other. The same author, in another work, entitled, Two Voyages to New England, calls this creature a monster of superfluity; and says, that when full

grown,

grown, it is many times larger than an ox. What Neal fays of this animal feems copied from Joſſelyn. But the beſt account we have of it, is from Mr. Paul Dudley. This gentleman ſays, that they are of two kinds: the common light-grey *moſe-deer*, called by the Indians *wumpoſe*, and the larger black *moſe*. The grey *moſe* is the ſame animal which Mr. Clayton, in his account of the Virginian quadrupeds, publiſhed in the Philoſophical Tranſactions, calls the elk; and this is the creature, deſcribed in the Anatomical Diſcoveries of the Paris Academy, under the name of the ſtag of Canada. Horns of this creature have been ſent from Virginia, and called elks horns: they are wholly the ſame with thoſe of our red deer, except in ſize; weighing about twelve pounds, and meaſuring from the burr to the tip about ſix feet long. Phil. Tranſ. N° 444. p. 386. abr. vol. vii. p. 447. See ELK.

Mr. Dudley ſays, that the grey *moſe* is like the Engliſh deer; and that theſe creatures herd together thirty or more in a company. The black or large *moſe* has been taken, he ſays, meaſuring fourteen ſpans in height from the withers, which, allowing nine inches to the ſpan, is ten feet and a half.

The ſtag or male of this kind has a palmed horn, not like that of our common or fallow deer, but the palm is much longer and more like to that of the German elk; but it differs from that in having a branched brow-antler between the burr and the palm, which the German elk hath not.

The large horns found foſſile in Ireland, have, from their vaſt dimenſions, been ſuppoſed to have originally belonged to the black *moſe-deer*; but they, as likewiſe moſt other of the large horns found in this part of the world, muſt be referred to the elk kind, but of a ſpecies different from the European, being provided with brow-antlers, which that wants. Some of theſe horns are near twelve feet between tip and tip, and ſix feet four inches long; and may probably be ranked among thoſe remains which foſſiliſts diſtinguiſh by the title of diluvian. The largeſt horns of the American *moſe* ever brought over are only thirty-two inches long, and thirty-four between tip and tip.

Mr. Ray mentions, in his Synopſis of Animals, a pair of extremely large foſſile horns, which he ſaw in a muſeum in Suſſex; but he mentions no brow-antlers in theſe, and therefore probably they, as well as ſome others preſerved in muſeums, were the horns of the German elk.

It is not agreed by authors what number of young the *moſe* brings forth at a time; Mr. Dudley ſays but two; but Joſſelyn, and from him Neal, ſay three; and theſe authors add, that they do not go ſo long with young as ours does, by two months.

There is, beſide the *moſe*, another animal of the deer-kind, very common in Virginia, and other of the northern provinces of America. This creature has round horns, not ſpreading out as in the ſtag or red deer, but meeting nearer together at the tips, and bending forwards over the creature's head; and the brow-antlers are not crooked and ſtanding forward, but ſtraight and upright. The ſkin of this deer is of a ſandy colour with ſome black hairs, and is ſpotted all over while young with white ſpots, as ſome of our fallow deer are, and it is about the bigneſs of our fallow deer when full grown.

The *dama Virginiana* of Mr. Ray was different from this, if the deſcription be exact, and the horns of the palmated kind. This *dama* of Mr. Ray ſeems to be what Joſſelyn, in his Voyages, calls the *mauvoiſe*; but his deſcription is too ſhort to form any regular judgment from; he only ſays, that the *mauvoiſe* is like the *moſe*, but that its horns are ſmall, and the creature about the bigneſs of a ſtag. Phil. Tranſ. N° 444. p. 388.

Joſſelyn mentions alſo the buck, the ſtag, and the reindeer; but it is very much to be doubted whether they are the ſame animals that we mean by thoſe names. He mentions alſo another ſort of American deer, an animal called a *macarib*, a *caribe*, or a *pohano*; but this ſeems a mere fiction; no ſuch animal exiſting in nature.

MOOT, formed either from the Saxon *motan*, *gemetan*, *meeting*; or from the French *mot*, *word*, a difficult caſe, or queſtion, argued by the ſtudents of inns of court, by way of exerciſe.

MOOTER, in the *Dock-Yards*, the perſon who forms and ſmooths the tree-nails for uſe.

MOOTING, the chief exerciſe of the ſtudents in the inns of court; being the arguing of caſes, which young utter barriſters, &c. perform at appointed times, the better to enable them for practice, and the defence of their clients cauſes.

Such as, from their learning and ſtanding, are called by the benchers to argue *moot-caſes*, are ſometimes called *utter barriſters*; the reſt, who, for want of experience, &c. are not admitted, are by ſome called *inner barriſters*. The place where the *moot-caſes* were argued, was anciently called a *moot-hall*.

In the inns of court there is a *bailiff* or *ſurveyor of the moots*, yearly choſen by the bench to appoint the *mootmen* for the inns of chancery, and to keep account of performance of exerciſes, both there and in the houſe.

MOOT-MEN, are thoſe who argue *moot-caſes*.

Out of theſe *moot-men* are choſen readers for the inns of chancery; where, in term-time, and in vacations, they argue caſes in the preſence of attornies and clerks.

MOP, in ſome counties in England, is the term for what is called the ſtatute in other places; being the time that young perſons who intend themſelves for ſervants, meet at ſome certain place, in order to be hired into ſervice.

MORAI, is the name given at Otaheite, in the South Sea, to their burying grounds, which are alſo places of worſhip. This is a pile of ſtone raiſed pyramidically upon an oblong baſe or ſquare, two hundred and ſixty-ſeven feet long, and eighty-ſeven wide. On each ſide is a flight of ſteps; thoſe at the ſides being broader than thoſe at the ends; ſo that it terminated not in a ſquare of the ſame figure with the baſe, but in a ridge, like the roof of a houſe. There were eleven of theſe ſteps to one of theſe *morais*, each of which was four feet high, ſo that the height of the pile was forty-four feet; each ſtep was formed of one courſe of white coral ſtone, which was neatly ſquared and poliſhed; the reſt of the maſs, for there was no hollow within, conſiſted of round pebbles, which, from the regularity of their figure, ſeemed to have been wrought. The foundation was of rock ſtones, which were alſo ſquared. In the middle of the top ſtood an image of a bird, carved in wood, and near it lay the broken one of a fiſh, carved in ſtone. The whole of this pyramid made part of one ſide of a ſpacious area or ſquare, 360 feet by 354, which was walled in with ſtone, and paved with flat ſtones in its whole extent. About a hundred yards to the weſt of this building was another paved area or court, in which were ſeveral ſmall ſtages raiſed on wooden pillars, about ſeven feet high, which are called by the Indians *ewattas*, and ſeem to be a kind of altars, as upon theſe are placed proviſions of all kinds, as offerings to their gods. On ſome of them were ſeen whole hogs, and on others the ſculls of above fifty, beſides the ſculls of many dogs. The principal object of ambition among the natives is to have a magnificent *morai*. The male deities, for they have them of both ſexes, are worſhipped by the men, and the female by the women; and each have *morais*, to which the other ſex is not admitted, though they have alſo *morais* common to both. Hawkeſworth's Voyages, vol. ii. p. 166—230.

MORALS, any thing relating to the manners or conduct of life.

Beſides the theological virtues, as *faith*, *hope*, *charity*, &c. there are alſo *moral* virtues; as *juſtice*, *temperance*, &c.

MORAL *actions*, or *acts*, are ſuch as render the agent *good*, or *evil*; and, conſequently, rewardable, or puniſhable, becauſe he does them. See ACTION.

MORAL *cauſe*. See CAUSE.

MORAL *certainty*, or *aſſurance*, is uſed to ſignify a very ſtrong probability; in contradiſtinction to a mathematical demonſtration. See CERTITUDE.

MORAL *evidence*, *evil*, *fables*, *good*. See the ſeveral ſubſtantives.

MORAL *impoſſibility*, is what we otherwiſe call a *very great*, and almoſt *inſuperable difficulty*; in oppoſition to a phyſical, or natural impoſſibility. See IMPOSSIBLE.

MORAL *liberty*, *neceſſity*, and *perfection*. See the ſubſtantives.

MORAL *philoſophy*, a ſcience whoſe object is, to direct and form men's manners; to explain the reaſon and nature of actions; and to teach and inſtruct us how to acquire that felicity which is agreeable to human nature.

Moral philoſophy is the ſame with what we otherwiſe call ETHICS, ſometimes MORALITY.

MORAL *quantity*. See QUANTITY.

MORAL *ſenſe*, the faculty whereby we diſcern or perceive what is good, virtuous, beautiful, &c. in actions, manners, characters, &c.

A late author has endeavoured to prove, that it is a peculiar ſenſe whereby we get the ideas of theſe things; and denominates it a *moral ſenſe*. See SENSE.

MORAL *theology* is that which treats of caſes of conſcience; called alſo *caſuiſtry*, or *caſuiſtical divinity*.

MORAL *univerſality*. See UNIVERSALITY.

MORAL *of a fable* is the inſtruction drawn from it.

Thus when Phædrus at the end of a fable adds, *Hoc illis dictum qui*, &c. this makes what we call the *moral*: the Greeks called it ἐπιμυθιον, when at the end of the fable; and προμυθιον, when at the beginning. Among the Latins it was called *affabulatio*.

MORALITIES, in *Engliſh Antiquity*. See MYSTERY.

MORALITY denotes a conformity, in things and actions, to those unalterable obligations which result from the nature of our exiſtence, and the neceſſary relations of life; whether to God as our creator, or to mankind as our fellow-creatures.

For other definitions of *morality* or virtue, given by ſome celebrated writers, as well as different hypotheſes relating to its foundation, ſee *Moral* VIRTUE.

MORALITY is alſo uſed for the ſcience or doctrine of morals, or the art of living well and happily; deduced from reaſon, and the nature, relation, and fitneſs of things.

In this ſenſe it amounts to the ſame with what we otherwiſe call *ethics*, *moral philoſophy*, or the *doctrine of offices*. Notwithſtanding the great obſcurity and uncertainties in the moral ſcience, Mr. Locke is of opinion, that the doctrine of manners is equally capable of being brought to demonſtration with the doctrine of quantity and number; that is, with the pureſt parts of mathematics.

According to this author, the idea of a Supreme Being, infinite in power, goodneſs, and wiſdom, whoſe workmanſhip we are, and on whom we depend; and the idea of ourſelves, as underſtanding, rational creatures; would, if duly conſidered, afford ſuch foundations of our duty, and rules of action, as might place *morality* among the ſciences capable of demonſtration; wherein we need not doubt but that, from principles as inconteſtible as thoſe of the mathematics, by neceſſary conſequences, the meaſure of right and wrong might be made out to any one, who will apply himſelf, with the ſame indifferency and attention, to the one, as he doth to the other of theſe ſciences: for the relations of other modes may certainly be perceived, as well as thoſe of number and extenſion. E. gr. that *where there is no property, there can be no injuſtice*, is a propoſition as certain as any in Euclid: for the idea of property being a right to any thing, and the idea of injuſtice being the invaſion or violation of that right, it is evident, that theſe ideas being thus eſtabliſhed, and theſe names annexed to them, we can as certainly know this propoſition to be true, as that a triangle has three angles equal to two right ones. Again, *no government allows abſolute liberty*: the idea of government being the eſtabliſhment of ſociety, upon certain rules or laws, which require conformity to them; and the idea of abſolute liberty being for any one to do whatever he pleaſes, I am as capable of being certain of the truth of this propoſition, as of any in mathematics.

What has given the advantage to the ideas of quantity, and made them thought more capable of certainty and demonſtration than the ideas of good and evil, right and wrong, &c. is,

1. That the former can be repreſented by ſenſible marks, which have a nearer correſpondence with them than any words or ſounds. Diagrams drawn on paper are copies of the ideas, and are not liable to the uncertainty that words carry in their ſignification; but we have no ſenſible marks that reſemble our moral ideas, and nothing but words to expreſs them by; which, though, when written, they remain the ſame, yet the ideas they ſtand for may change in the ſame man, and it is very ſeldom that they are not different in different perſons.

2. Moral ideas are commonly more complex than figures; whence theſe two inconveniences follow: 1. That their names are of more uncertain ſignification; the preciſe collection of ſimple ideas they ſtand for not being ſo eaſily agreed on; and ſo the ſign that is uſed for them in communication always, and in thinking often, does not readily carry with it the ſame idea.

2. The mind cannot eaſily retain thoſe preciſe combinations ſo exactly and perfectly, as is neceſſary in the examination of the habitudes and correſpondences, agreements or diſagreements, of ſeveral of them one with another, eſpecially where it is to be judged of by long deductions, and the intervention of ſeveral other complex ideas, to ſhew the agreement or diſagreement of two remote ones.

One part of theſe diſadvantages in moral ideas, which has made them be thought not capable of demonſtration, may in a good meaſure be remedied by definitions, ſetting down that collection of ſimple ideas which every term ſhall ſtand for, and then uſing the term ſteadily and conſtantly for that preciſe collection.

The mathematician conſiders the truth and properties belonging to a rectangle or circle, only as they are ideas in his own mind, which poſſibly he never found actually exiſted mathematically, that is, preciſely, true: yet his knowledge is not only certain, but real; becauſe real things are no farther, nor intended to be, meant by any ſuch propoſitions, than as things really agree to thoſe archetypes in the mind. It is true of the idea of a triangle, that its three angles are equal to two right ones; it is true alſo of a triangle, wherever it exiſts: what is true of thoſe figures that have barely an ideal exiſtence in the mind, will hold true of them alſo, when they come to have a real exiſtence in matter. Hence it follows, that moral knowledge is as capable of real certainty as mathematics: for certainty being nothing but the perception of ſuch agreement, by the intervention of other ideas; our moral ideas, as well as mathematical, being archetypes themſelves, and ſo adequate or complete ideas, all the agreement or diſagreement we ſhall find in them will produce real knowledge, as well as in mathematical figures. That which is requiſite to make our knowledge certain, is the clearneſs of our ideas; and that which is required to make it real, is that they anſwer their archetypes.

But it will here be ſaid, that if moral knowledge be placed in the contemplation of our own moral ideas, and thoſe are of our own making, what ſtrange notions will there be of juſtice and temperance! what confuſion of virtues and vices, if every man may make what ideas of them he pleaſes? It is anſwered, no confuſion or diſorder at all in the things themſelves, nor the reaſonings about them, no more than there would be a change in the properties of figures, and their relations one to another, if a man ſhould make a triangle with four corners, or a trapezium with four right angles; that is, in plain Engliſh, change the names of the figures, and call that by one name which is called ordinarily by another. The change of name will indeed at firſt diſturb him who knows not what idea it ſtands for; but as ſoon as the figure is drawn, the conſequences and demonſtration are plain and clear.

Juſt the ſame is it in moral knowledge: let a man have the idea of taking from others, without their conſent, what they are juſtly poſſeſſed of, and call this *juſtice*, if he pleaſeth; he that takes the name there, without the idea put to it, will be miſtaken, by joining another idea or his own to that name; but ſtrip the idea of that name, or take it, ſuch as it is in the ſpeaker's mind, and the ſame things will agree to it, as if you called it *injuſtice*. One thing we are to take notice of, that where God, or any other law-maker, has defined any moral names, there they have made the eſſence of that ſpecies to which that name belongs; and there it is not ſafe to apply or uſe them otherwiſe; but in other caſes it is bare impropriety of ſpeech to apply them contrary to the common uſage of the country they are uſed in.

MORASS, a marſh, fen, or low moiſt ground, which receives the waters from above, without having any deſcent to carry them off again.

Somner derives the word from the Saxon *merſe*, *lake*; Salmaſius from *mare*, *a collection of waters*; others from the German *moraſt*, *a muddy place*; and others from *marſc*, of *mariſcum*, *à mariſci*, *i. e. ruſtici*. See BOG, FEN, MARSH, &c.

In Scotland, Ireland, and the north of England, they have a peculiar kind of *moraſſes*, called *moſſes*, or *peat-moſſes*, whence the country people dig their peat or turf, for firing.

The earl of Cromertie gives a particular account of theſe moſſes in the Philoſophical Tranſactions. They are covered with a heathy ſcurf, under which is a black, moiſt ſpongy earth, in ſome places ſhallower, in others deeper, ordinarily from three or four, to ſeven or eight feet depth, though in ſome few places twice or thrice as much.

This black ſpongy earth they cut into oblong ſquares with iron ſpades made for that purpoſe, eight or nine inches long, and four or five broad: as the men cut them up, they are carried and ſpread on a dry ground, to be dried in the wind and ſun. Some of theſe become harder, ſome ſofter, according to the nature of the mould or earth: the more black and ſolid they are, the better fire they make; and thoſe are the leaſt eſteemed which are greyeſt, lighteſt, and moſt ſpongy.

When they have cut off one ſurface of four or five inches deep, they proceed downwards to another, and ſo to a third and a fourth, till they come to the hard ſtrata; unleſs they be ſtopped with water, which they alſo ordinarily remove by making a channel, if they can; but where they cannot, there the water ſtagnates. In ſuch waſted pits, or *peat-dikes*, as they call them, where water hinders the cutting the ſpongy earth to the bottom, the pits will be filled up again, in ſome years, with a new ſpongy earth; which, in proceſs of time, comes to the conſiſtence of peat-moſs as at firſt, and a ſcurfy heathy turf grows over the top of it. When the dikes are dug down to the hard channel, the moſſes do not renew, as in the other caſe; though it has been obſerved, that if they be cut down to the channel, provided the heathy turf cut off from the top be but laid on the channel, in courſe of time the moſs grows again. Theſe moſſes are always level; though they are frequently found on hills, and near the tops of them too; yet, as that curious nobleman obſerves, the moſſes have always a deſcent to them, and

generally from them; insomuch that he never knew any where the water might stagnate. It is the water draining from above, that seems to be the parent of the peat. In many of these mosses are found quantities of fir and oak-wood, usually in whole trees; but the smaller branches are seldom found unconsumed. This wood is as good for use as any old wood is; only that, having imbibed a deal of moisture, it takes some time to dry, in order to fit it for burning.

There are many places where wood will not grow, where yet the mosses are well stocked with this under-ground timber; but yet it appears there must have been woods formerly there; else how came they in the mosses? To prove this, that noble lord gives us the history and origin of a moss, in great measure from his own experience. In the parish of Lochburn, in the year 1651, he saw, near the top of a very high hill, a plain about a mile over, then covered with a firm standing wood, but which was so very old, that not only the trees had no leaves or bark on, but the outside, for the space of an inch inwards, was dead white timber, though within they were firm. Coming by the place fifteen years after, he could not discover the least appearance of a tree; but, instead thereof, there was a plain green ground covered with a moss; the trees being all fallen, and having lain so thick over one another, that the green had over-run the whole timber, by means of the moisture draining from the hill above it, and stagnating on the plain. He adds, that none could pass over it; the scurf not being firm enough to support them. In thirty years more he found this whole piece of ground turned into a common peat-moss, and the country people digging turf and peat there. This accounts for the generation of mosses, and whence it is that many of them are furnished with timber.

It appears from the whole, that all the trees which we find in this fossile state, originally grew in the very places where we now find them, and have only been thrown down and buried there, not brought from elsewhere. It may appear indeed an objection to this opinion, that most of these fossile trees are of the fir-kind; and that Cæsar says expressly, that no firs grew in Britain in his time; but this is easily answered by observing, that these trees, though of the fir-kind, yet are not the species usually called the fir, but pitch-tree; and Cæsar has no where said that pitch-trees did *not* grow in England. Norway and Sweden yet abound with these trees, and there are at this time whole forests of them in many parts of Scotland, and a large number of them wild upon a hill at Wareton in Staffordshire to this day.

In Hatfield-marsh, where such vast numbers of the fossile trees are now found, there has evidently once been a whole forest of them growing. The last of these was found alive, and growing in that place within a hundred years last past, and cut down for some common use. See *Bog-Wood*.

The Roman historians tell us, that when their armies pursued the wild Britons, these people always sheltered themselves in the miry woods, and low watery forests. Cæsar expressly says this, and observes, that Cassibelan and his Britons, after their defeat, passed the Thames, and fled into such low *morasses* and woods, that there was no pursuing them; and we find that the Silures secured themselves in the same manner when attacked by Ostorius and Agricola. The same thing is recorded of Venutius, king of the Brigantines, who fled to secure himself into the boggy forests of the midland part of this kingdom; and Herodian expressly says, that, in the time of the Romans pushing their conquests in these islands, it was the custom of the Britons to secure themselves in the thick forests which grew in their boggy and wet places, and when opportunity offered, to issue out thence, and fall upon the Romans. The consequence of all this was, the destroying all these forests, the Romans finding themselves so plagued with parties of the natives issuing out upon them at times from these forests, that they gave orders for the cutting down and destroying all the forests in Britain which grew on boggy and wet grounds. These orders were punctually executed; and to this it is owing that at this day we can hardly be brought to believe that such forests ever grew with us as are now found buried.

The Roman histories all join in telling us, that when Suetonius Paulinus conquered Anglesea, he ordered all the woods to be cut down there, in the manner of the Roman generals in England; and Galen tells us, that the Romans, after their conquest in Britain, kept their soldiers constantly employed in cutting down forests, draining of marshes, and paving of bogs. Not only the Roman soldiers were employed in this manner, but all the native Britons made captives in the wars, were obliged to assist in it; and Dion Cassius tells us, that the emperor Severus lost no less than fifty thousand men in a few years time, in cutting down the woods, and draining the bogs of this island. It is not to be wondered at, that such numbers executed the immense destruction which we find in these buried forests. One of the greatest subterranean treasures of wood is that near Hatfield; and it is easy to prove that these people, to whom this havock is thus attributed, were upon the spot where these trees now lie buried. The common road of the Romans out of the south into the north, was formerly from Lindum (Lincoln) to Segelochum (Little-Borrow upon Trent), and from thence to Danum (Doncaster), where they kept a standing garrison of Crispinian horse. A little off on the east, and north-east of their road, between the two last named towns, lay the borders of the greatest forest, which swarmed with wild Britons, who were continually making their sallies out, and their retreats into it again, intercepting their provisions, taking and destroying their carriages, killing their allies and passengers, and disturbing their garrisons. This at length so exasperated the Romans, that they were determined to destroy it; and to do this safely and effectually, they marched against it with a great army, and encamped on a great moor not far from Finningley: this is evident from their fortifications, yet remaining.

There is a small town in the neighbourhood called Osterfield, and as the termination *field* seems to have been given only in remembrance of battles fought near the towns whose names ended with it, it is not improbable that a battle was fought here, between all the Britons who inhabited this forest, and the Roman troops under Ostorius. The Romans flew many of the Britons, and drove the rest back into this forest, which at that time overspread all this low country. On this the conquerors taking advantage of a strong south-west wind set fire to the pitch trees, of which this forest was principally composed; and when the greater part of the trees were thus destroyed, the Roman soldiers and captive Britons cut down the remainder, except a few large ones, which they left standing, as remembrances of the destruction of the rest. These single trees however could not stand long against the winds; and these falling into the rivers which ran through the country, interrupted their currents, and the water then overspreading the level country, made one great lake, and gave origin to the *mosses* or moory bogs, which were afterwards formed there, by the workings of the waters, the precipitation of earthy matter from them, and the putrefaction of rotten boughs and branches of trees, and the vast increase of water moss, and other fuel plants which grow in prodigious abundance in all these sorts of places. Thus were these burnt and felled trees buried under a new-formed spungy and watery earth; and afterwards found, on the draining and digging through this earth again.

Hence it is not strange, that Roman weapons and Roman coins are found among these buried trees; and hence it is that among the buried trees some are found burnt, some chopped and hewn; and hence it is that the bodies of the trees all lie by their proper roots, and with their tops lying north-east, that is, in that direction in which a south-west wind would have blown them down. Hence also it is, that some of the trees are found with their roots lying flat, these being not cut or burned down, but blown up by the roots afterwards when left single; and it is not wonderful that such trees as these should have continued to grow even after their fall, and shoot up branches from their sides, which might easily grow into high trees. Phil. Trans. N° 255.

By this system it is also easily explained why the moor soil in the country is in some places two or three yards thicker than in others, or higher than it was formerly, since the growing up of peat-earth or bog-ground is well known, and the soil added by overflowing of waters is not a little.

As the Romans were the destroyers of this great and noble forest, so they probably were also of the several other ancient forests; the ruins of which furnish us with the bog-wood of Staffordshire, Lancashire, Yorkshire, and other counties. But as the Romans were not much in Wales, in the Isle of Man, or in Ireland, it is not to be supposed, that forests cut down by these people gave origin to the fossile wood found there; but though they did not cut down these forests, others did; and the origin of the bog-wood is the same with them and with us. Hollinghead informs us, that Edward the First being not able to get at the Welch, because of their hiding themselves in boggy woods, gave orders at length that they should be destroyed by fire and by the ax; and doubtless the roots and bodies of trees found in Pembrokeshire under ground, are the remains of the execution of this order. The fossile wood in the bogs of the Isles of Man and Anglesea, is doubtless of the same origin; though

we have not any accounts extant of the time or occasion of the forests there being destroyed; but as to the fossile trees of the bogs of Ireland, we are expressly told, that Henry the Second, when he conquered that country, ordered all the woods to be cut down that grew in the low parts of it, to secure his conquests by cutting away the places of resort of rebels.

We have an account in the Philosophical Transactions of a moving moss, near Church-town in Lancashire, which greatly alarmed the neighbourhood as miraculous. The moss was observed to rise to a surprising height, and soon after sunk as much below the level, and moved slowly towards the south. See *Moving* BOG.

MORAVIAN, or BOHEMIAN *brethren*, in *Ecclesiastical History*, were protestants of Bohemia, who, in the fifteenth century, threw off the despotic yoke of Rome, animated by the zealous exhortations and heroic example of John Huss. These *Moravian* brethren were distinguished by several religious institutions of a singular nature, and well adapted to guard their community against the reigning vices and corruptions of the times. In 1552 they united themselves to the Lutheran churches in Saxony; but after the death of Luther, and their expulsion from their country in 1547, many of them, who retired into Poland, embraced the religious sentiments and discipline of the reformed; and by degrees they all entered into the communion of the Swiss church. This union was, at first, formed on the express condition, that the two churches should continue to be governed by their respective laws and institutions, and should have separate places of public worship; but, in the following century, all remains of diffension were removed in the synods held at Astrog in 1620 and 1627, and the two congregations were formed into one, under the title of the *Church of the United Brethren*. From this honourable origin the modern *Moravians* pretend to derive their descent. See HERRNHUTERS.

MORATUR, or DEMORATUR, in *Law*, signifies as much as, *he demurs*; that is, the party here goes not forward, but rests or abides by the judgment of the court, who take time to deliberate, argue, and advise thereon.

When the counsel of the party are of opinion, that the count or plea of the adverse party is insufficient in law; then he *demurs*, or abides in law, and refers the same to the judgment of the court. See DEMURRER.

MORBID, *morbidus*, in *Medicine*, is applied to those parts, humours, &c. wherein a disease lies.

MORBID, in *Painting*, is particularly applied to fat flesh very strongly expressed.

MORBILLI, in *Medicine*, a disease popularly called MEASLES.

MORBUS, a term purely Latin, signifying DISEASE.

MORBUS *caducus* denotes the EPILEPSY.

MORBUS *Gallicus*. See VENEREAL *disease*.

MORBUS *Hungaricus*. See HUNGARICUS *morbus*.

MORBUS *prodromus*. See PRODROMUS.

MORBUS *pedicularis*. See PEDICULARIS.

MORBUS *regius*. See JAUNDICE.

MORBUS *strigosus*. See CHLOROSIS.

MORBUS, *cholera*. See CHOLERA.

MORDEH, an East Indian name for a disease, to which the people of that country are subject. It consists in a violent disorder of the stomach. The great heats, copious sweats, and supervening cold of that country, all naturally tend to weaken the stomach. Now if the inhabitants eat or drink immoderately at night, the concoction of their aliments can be but very unduly performed. Hence, besides this distemperature of the stomach, they are subject to others of the bowels; and diarrhœas are very common among them, and with difficulty cured.

MORDELLA, a name given by some writers to the EARWIG.

MORDELLA, in *Zoology*, the name of a genus of four-winged flies, of the *coleoptera* order of insects; the characters of which are, that the antennæ are filiform and serrated; the head deflexed under the neck; that the palpi are compressed, elevated, and obliquely truncated; that the elytra are bent downwards towards the apex; and that the fore-thighs are broad at the base of the abdomen. Linnæus enumerates six species. See INSECT. Dr. Hill distinguishes this genus by slender antennæ, the last joint being globose, and by most of the species having legs, which serve them for leaping. Hist. Anim. p. 40.

MORDEXYN, or MORDOXI, a name given to a disease very frequent among the inhabitants of Goa, which consists in a nausea, and continued vomiting, and usually seizes the patient suddenly and unexpectedly, and often proves fatal.

MORDILAPIS, a name given by some writers to loaches, a small fish, often found under stones in shallow waters.

MORE'S-*head*, in the *Manege*, implies the colour of a *roan-horse*, who, besides the mixture or blending of a grey and a bay, has a black head, and black extremities, as the main and tail. See ROAN.

MORÆA, in *Botany*, a genus of the *triandria monogynia* class. Its characters are these: the flower is very like those of the iris, but it has six spear-shaped petals, which spread open horizontally; three of which are alternately longer than the other; and it has three erect standards, which have no falls as the irises have; the spatha, number of stamina, and seed-vessel, agree very nearly with the iris. Linnæus reckons five, and Miller three species, natives of the Cape of Good Hope.

MORELLA, in *Botany*, a name used by some as a common term for all the nightshades; others have appropriated it to the *lycopersicum*, or love-apple only. Æmilius Macer tells us, that in his time all the plants called by the Greeks *strychna*, were called by the Latins *morella*.

MORESK, or MORISKO, a kind of painting, carving, &c. done after the manner of the Moors; consisting of several grotesque pieces and compartiments promiscuously interminghed, not containing any perfect figure of a man, or other animal, but a wild resemblance of birds, beasts, trees, &c.

These are also called *arabesques*, and are particularly used in embroideries, damask-work, &c.

Moresque-dances, vulgarly called *morrice-dances*, are those altogether in imitation of the Moors; as farabands, chacons, &c. and are usually performed with castanets, tambours, &c.

There are few country places in this kingdom where the *morrice-dance* is not known. It was probably introduced into this country about, or a little before, the reign of HENRY VIII. and is a dance of young men in their shirts, with bells at their feet, and ribbands of various colours tied round their arms, and flung across their shoulders.

MORETUM, among the Romans, a kind of sallad, composed of the eight following ingredients, viz. garlic, parsley, rue, coriander, onions, cheese, oil, and vinegar.

MORGANATIC *marriage*. See MARRIAGE.

MORGAY, an English name for the sea-fish, called also the *rough hound-fish*, one of the galeus kind; the *catulus minor* of Salvian, and *mustelus stellatus tertius* of Belonius.

It is of a pale, and somewhat reddish grey, and is spotted with brown and whitish spots; the belly is silver white, and the body long and round; its skin is very rough, and its flesh very firm, and finely flavoured; some say it tastes of musk, or some such perfume. It is the smallest of all this genus of fishes, and seldom weighs above a pound and a half. It is common in the Mediterranean, and is frequent in the markets in Italy.

MORGH, among the *Mahometans*, a sect who lay much stress upon belief, and stand opposed to the ALWAIDII.

MORHUA, in *Zoology*, a name used by some authors for the common cod-fish.

MORIAM, in our *Old Writers*, a head-piece called a pot, stat. 4 & 5 P. & M. c. 2.

The word comes from the French *morion*, or Italian *morione*, i. e. *casque*.

MORILLES, a kind of mushroom, about the bigness of a walnut, pierced with holes like a honey-comb, and said to be good for creating an appetite. They are also accounted restorative, and frequently used in sauces and ragouts.

MORILLON, in *Zoology*, the name of a species of duck, seeming the same with the *capo rosso*, a small red-headed wild duck. See DUCK.

MORINA, in *Botany*, a genus of the *diandria digynia* class. Its characters are these: it has a double empalement, which is tubulous, bifid, of one leaf, and permanent; the flower hath one petal, with a long tube a little incurved; the top is divided into two lips; the upper lip is small and bifid; the under lip is cut into three equal obtuse segments, the middle one being extended beyond the other; it hath two bristly stamina; the globular germen is situated under the flower, supporting a slender style, which is longer than the stamina, and crowned by a target-shaped stigma; the germen afterward becomes a single seed, crowned by the empalement of the flower. There is but one species of this genus known at present, which grows naturally near Erzeron, in Persia. It is cordial, cephalic, and stomachic; good for resisting the influence of a bad air, and to excite the transpiration of peccant humours, being taken in infusion or conserve.

MORINDA, in *Botany*, a genus of the *pentandria monogynia* class. Its characters are, that the flowers are aggregate and monopetalous; the stigma divided into two segments, and the fruit aggregate drupes. There are three species.

MORINELLUS, in *Zoology*. See DOTTEREL, and TURNSTONE.

MORINGA, in *Botany*, the name by which some authors call the tree which produces the ben nut, or *glans unguentaria*, and whose wood is the *lignum nephriticum*, or nephritic wood of the shops.

MORION, in *Botany*, a name given by the ancients to a kind of nightshade. The ancient Greeks, Theophrastus, and others, called all the nightshades in general by the name *strychnos*. Some of these they said were poisonous, and other esculent. The poisonous were of two kinds, some bringing on sleepy disorders, and others making the patient mad.

The esculent kind was the *pomum amoris*, or love-apple, eaten at this time by the Portuguese, and many other nations, and by some in England. Some after-writers use the word *morion* as a distinctive name for those kinds of nightshade which caused sleepy disorders; and after these, some used it as the peculiar name of one species, and others as the name of the male mandrake of Dioscorides, whose fruit, according to that author, was commonly eaten by the shepherds; but when taken too largely, threw them into sleepy disorders. From this word *morion* has come, in all probability, the Latin name *morella*, given at first to the *pomum amoris*, or love-apple; and afterwards, according to Æmilius Macer, to all the nightshades; for he expressly says, that those plants which the Greeks called *strychnos*, the Latins called *morella*; and we find that the old Greeks called all the nightshades *strychnos*.

MORION, in the *Natural History of the Ancients*, a name given to one of the semi-pellucid gems, more commonly called HAMMON. It is a stone appearing externally only of a fine deep black; but when held up against a candle, or against the sun-shine, giving a very beautiful red, in different degrees, from that of the hyacinth to that of the amethyst or carbuncle.

MORISONIA, in *Botany*, the name of a genus of plants of the *monadelphia polyandria* class; the characters of which are these: the perianthium is one leaved, inflated, and divided at the top into two lips; these stand open; but the neck is contracted, and the whole soon withers; the flower consists of four oblong obtuse petals, which are expanded when they are out of the cup; the stamina are numerous filaments; the anthers are simple; the style is capillary and erect, and is longer than the tube of the flower; the germen of the pistil is oval; the stigma is capitated, and of a plano-convex figure; the fruit is a globose berry, with a hard smooth rind; it has only one cell, and is supported by the style by way of pedicle; the seeds are numerous, and are of the shape of the common kidney-beans, but small. Linnæi Gen. Plant. p. 230.

MORLING, or MORTLING, in our *Old Writers*, the wool which is taken from the skin of dead sheep, whether killed, or dying of the rot. See SHORLING.

MORMYLUS, in *Ichthyology*, the name of a species of SPARUS, with the upper jaw longest, and with twelve parallel, transverse black lines on each side.

MORMYRUS, in *Ichthyology*, a genus of abdominal fish, with a smooth head, several emarginated teeth, a linear aperture in the gills, without a cover, and squamose body. There are two species, inhabitants of the Nile.

MORNING, the beginning of the day; or the time of the sun-rising.

The astronomers reckon *morning*, *noon*, from the time of midnight, to that of mid-day. Thus an eclipse is said to begin at eleven o'clock in the *morning*, &c.

MORNING *star* is the planet Venus, when a little to the westward of the sun; that is, when she rises a little before him. In this situation she is called, by the Greeks, *Phosphorus*; by the Latins, *Lucifer*, &c.

MORNING *twilight*. See CREPUSCULUM.

MOROCCO, or MAROQUIN, the skin of a goat, or some other animal resembling it, dressed in sumac or galls, and coloured of any colour at pleasure; much used in book-binding, &c.

The name is ordinarily derived from the kingdom of *Morocco*, whence it is supposed the manner of preparing these skins was first borrowed.

We have *Morocco* skins brought from the Levant, Barbary, Spain, Flanders, and France; red, black, yellow, blue, &c. The various manners of preparing *Morocco*, both black and in colours, are so curious, and withal so little known among us, that the public will not be displeased to find them here.

MOROCCO, *manner of preparing black*. The skins having been dried in the hair, are steeped in clear water three days and nights; then they are stretched on a wooden horse or leg, like that used by tanners; then beaten with a large knife for the purpose, and steeped afresh in water, changed daily till they be well come again. In this state they are thrown into a large vat in the ground, full of water, wherein quicklime has been flaked, where they lie fifteen days; whence, however, they are taken, and again returned every night and morning; they are thrown into a fresh vat of lime and water, and shifted night and morning, as before, for fifteen days longer; then rinsed in clear water; and the hair is then taken off, on the leg, with the knife; the skins are then returned into a third vat, and shifted, as before, for about eighteen days; then steeped twelve hours in a river; then taken out, rinsed, put in pails, where they are pounded with wooden pestles, changing the water twice; then laid on the horse, and the flesh taken off, returned into pails of new water, taken out, and the hair-side scraped; then returned into fresh pails, taken out, and thrown into a pail of a particular form, having holes at bottom; here they are beaten the space of an hour, and fresh water poured on from time to time; stretched on the leg, and scraped on either side; returned into pails of fresh water; taken out, stretched, and sewed up all around in manner of bags, leaving out the hind legs, which serve to make an aperture for the conveyance of a mixture mentioned hereafter.

The skins, thus sewed, are put in lukewarm water, where dogs excrement has been dissolved. Here they are stirred with long poles half an hour, left at rest a dozen, taken out, rinsed in fresh water, and filled by a tunnel with a preparation of water and sumac, mixed and heated over the fire till ready to boil; and as they are filled, the hind legs are sewed up to stop the passage. In this state they are let down into the vessel of water and sumac, and kept stirring four hours successively; they are then taken out, and heaped on one another; after a little time, their sides are changed; and thus they continue an hour and a half, till drained. This done, they are loosened, and filled a second time with the same preparation, sewed up again, and kept stirred two hours, piled up, and drained as before. This is again repeated a third time, with this difference, that they are now only stirred a quarter of an hour; after which, they are left till the morrow morning, when they are taken out, drained on a rack, unsewed, the fumac taken out, folded in two from head to tail, the hair-side outwards, laid over each other on the leg, to perfect their draining, stretched out, and dried; then trampled under-foot by two and two, stretched on a wooden table, what flesh and sumac remains scraped off, and the hair-side rubbed over with oil, and that again with water.

Having thus received their oil and water, they are wrung in the hands, then stretched and pressed right on the table with an iron instrument like that of the curriers, the flesh-side uppermost; then turned, and the hair-side rubbed strongly over with a handful of rushes, to squeeze out as much of the oil remaining within as possible. The first course of black is now laid on the hair-side, by means of a lock of hair twisted and steeped in a kind of black dye, prepared of sour beer, wherein pieces of old rusty iron have been thrown. When half dry, by hanging in the air, they are stretched on a table, and rubbed over every way with a paumelle, or wooden-toothed instrument, to raise the grain, over which is passed a light couche of water, then flocked by rubbing them with rushes prepared for the purpose. Thus flocked, they have a second couche of black; they are then dried, laid on the table, rubbed over with a paumelle of cork, to raise the grain again; and, after a light couche of water, flocked over anew; and, to raise the grain a third time, a paumelle of wood is used.

After the hair-side has thus received all its preparations, the flesh-side is pared with a sharp knife for the purpose, and the hair-side rubbed strongly over with a woollen cap, having first given it a lustre with barberries, citron, or orange. The whole is finished by raising the grain lightly, for the last time, with the paumelle of cork, which leaves them in a condition for sale and use.

MOROCCO, *manner of preparing red*. The skins are steeped twenty-four hours in a river, taken out, stretched on the leg, beaten with the knife, returned into the water for twenty-four hours, re-beaten on the leg, re-steeped; thrown into a vat, and for three weeks taken out, and returned every morning, to dispose them to peel. Being taken out for the last time, they are scraped with the knife, and when the hair is quite off, thrown into pails of fresh water, where they are rinsed; then the flesh-side scraped, thrown into the pails, and thus alternately from the leg to the pails, till they leave the water quite clean; then they are put in lukewarm water, with the sumac as before; and, after twelve hours, they are rinsed in clear water, and scraped on the leg on both sides, pounded in pails, and the water changed three times; then wrung, and stretched on the leg, and pailed after each other into water, with alum dissolved in it. Thus alumed, they are left to drain till the morning, then wrung out, pulled on the leg, and folded from head to tail, the flesh inwards.

In this state they receive their first dye, by passing them one

one after another into a red liquor, prepared with laccs, and some other ingredients, kept secret among the *morequinners*. This they repeat again and again, till the skins have got their first colour. They are then rinsed in clear water, stretched on the leg, and left to drain twelve hours; then thrown into water, into which white galls pulverized have been passed through a sieve, and stirred incessantly for a whole day with long poles, taken out, hung on a bar across the water all night, white againſt red, and red againſt white; and in the morning the water is stirred up, and the skins are returned into it for twenty-four hours. See DYEING *of leather*.

MOROCHITES, in *Natural History*, a name by which some of the old authors have called the *marochthus*, or French chalk.

MOROCHTHUS, in the *History of Fossils*, a name of an indurated clay, commonly known among us by the name of French chalk, or marking-stone; and its principal use with us is the taking of spots out of cloaths, and the ſerving taylors to mark with, as it makes a much more determinate and a neater line than chalk. The ancients, however, had it much in eſteem in medicine, and used it as an aſtringent, and in colics and hæmorrhages, and externally in ulcerations of the eyes.

It is diſtinguiſhed from all other earths, by being the hardeſt of all, conſiderably heavy, ſemi-tranſparent, of a very ſmooth, unctuous, glaſſy ſurface, and of a greyiſh white colour, with a conſiderable admixture of green; it is of a diſagreeable brackiſh taſte, and does not ferment with acids; it does not colour the hands, nor adhere to the tongue, nor melt in the mouth, and it is not diſſuſible in water. It burns to a great hardneſs, and a white colour. It is dug in Germany, the iſland of Sardinia, and many other places; but no where ſo pleniſully about Bruncon in France, whence it is there commonly called *Bruncon d'alk*.

MOROCTES, one of the names by which Pliny, and ſome other of the older authors, called the *morochthus*, or French chalk.

MORONA, a name uſed by ſome for the HUSO, or iſinglaſs-fiſh.

MORPHASMUS, *μορφασμος*, among the *Antients*, a kind of dance, wherein, by a great many figures, they imitated the tranſformations of Proteus.

MORPHEW, *morphœa*, a leproſy ſort of freckle or ſcurf, which breaks out ſometimes upon the ſkin, particularly about the forehead; called alſo *alphus*.

MORRHA, in *Natural History*, a name given by ſome to the ſubſtance more properly called *murra* or *myrrha*, of which the cups called MURRHINA and *myrrhina* were made.

MORRHINA *vaſa*, in the *Writings of the Ancients*. See MURRHINA.

MORRICE-*dance*. See MORRIS.

MORSE, in *Zoology*, the name of a monſtrous ſea animal, called by ſome the *rosmarus* and *rosmarus*, and by others, very improperly, the *hippopotamus* and *equus marinus*.

The *morſe*, or TRICHECUS *roſmarus* of Linnæus is an ill-ſhaped amphibious animal, of the ſize of a large ox, covered with a hair like that of the ſeal, and ſomewhat reſembling an ox in the head; for which reaſon ſome have called it the ſea-cow, or *cavea marina*; whence it has been erroneouſly confounded by ſome with the *manati*.

It has two large prominent and crooked tuſks in the upper jaw, which are as fine as ivory, and are uſed by artificers for the ſame purpoſes; and four grinders on both ſides above and below, but no cutting teeth: the teeth have been ſometimes found of the weight of twenty pounds each; it brings forth uſually but one young at a time, never more than two. It is a very ſtrong and vigorous animal, and difficultly taken; when it is caught, it is uſually at land, ſeldom at ſea. See *Tab.* III. *Quadrupeds*, N° 37.

Vorſtius, who met with a young one of this creature, has very accurately deſcribed it; whence we have the beſt deſcription extant of the nature of the animal. This young one was of the ſize of a large dog, and in ſhape much reſembled the phoca or ſea-calf. Its head was round; its eyes large, and like thoſe of an ox; its noſtrils diſtended and wide, and opening, and drawing together as the creature pleaſed; it had apertures on the ſides of the head for ears; its mouth opened round, and not very large; and on the upper lip it had a ſort of whiſkers, compoſed of thick cartilaginous briſtles; the lower jaw was of a trigonal form; the tongue ſhort and thick, and the mouth well furniſhed with broad and flatted teeth; its fore-feet, as well as the hinder ones, were very broad; and the hinder extremity of its body very much reſembled that of the *phoca* or ſea-calf: when it walked, the fore-feet were directed forwards, the others turned backward; the toes were five on each foot, and theſe were joined by a membrane, which was remarkably thick; the hinder feet had claws, the fore ones had none; and the creature had no tail, and crept rather than walked on the hinder parts; its ſkin was thick and tough, and covered with a few ſhort grey hairs; it made a noiſe like the grunting of a hog.

Theſe animals inhabit the coaſt of Spitzbergen, Nova Zembla, Hudſon's Bay, and the Gulph of St. Lawrence, and the icy ſea, as far as Cape Iſchukitſchi; they are gregarious: in ſome places appear in herds of hundreds: are thy animals, and avoid places that are much haunted by mankind. The method of killing them on the Magdalene iſles is ſaid to be as follows: the hunters watch their landing, and as ſoon as they find a ſufficient number for what they call a *cut*, go on ſhore, each armed with a ſpear, ſharp on one ſide like a knife, with which they cut their throats, taking care not to ſtand in the way of thoſe which attempt to get again to ſea, which they do with great agility, by tumbling headlong; for they would crush any body to death by their vaſt weight. They are killed for the ſake of their oil, one *cut* producing about half a tun. The knowledge of this chace is of great antiquity: Other, the Norwegian, about the year 890, made a report of it to king Alfred, ſaying, as he ſays, made the voyage beyond Norway, for the convenience of fiſhing for *horſe whales*, which have in their teeth bones of great value, of which he brought ſome at his return to the king. Pennant.

MORSELLI, or MORSULI, are denominations given to thoſe forms of medicine intended to be ſucked in the mouth, as a *lozenge*; the word ſignifying a little mouthful.

MORSUS *diaboli, devil's bit*, a plant of the ſcabious kind, which ſeems to have a fringe around the bottom of its root; otherwiſe called *ſucciſa*. See SCABIOUS.

It has its denomination from its roots, which appear as if bitten off at the bottom; which ſuperſtitious people attributed to the devil, as done out of envy, leſt we ſhould have too much of ſo ſalutary a root. It was formerly looked on as a good alexipharmic; but is now much out of uſe.

From a likeneſs to this plant, the edge or ſelvedge of the tubæ Falloppianæ has obtained the ſame appellation.

MORSUS *canis rabidi*. See HYDROPHOBIA.

MORSUS *ranæ*. See HYDROCHARIS.

MORSUS *viperæ*. See VIPER.

MORT *d'anceſtre*, in *Law*. See ASSIZE *of mort d'ancestre*.

MORT, among the fiſhermen of ſome parts of England, a name given to the SALMON while in its third year's growth.

MORTALITY, a term frequently uſed to ſignify a contagious diſeaſe, which deſtroys great numbers of either men, or beaſts.

MORTALITY, *bills of*, are accounts or regiſters ſpecifying the numbers born, married, and buried in any pariſh, town, or diſtrict. In general they contain only theſe numbers; and, even when thus limited, are of great uſe, by ſhewing the degrees of healthineſs and proliſickneſs, and the progreſs of population in the places where they are kept. It is therefore much to be wiſhed, that ſuch accounts had been always correctly kept in every kingdom, and regularly publiſhed at the end of every year. We ſhould then have had under our inſpection the comparative ſtrength of every kingdom, as far as it depends on the number of inhabitants, and its increaſe or decreaſe at different periods.

But ſuch accounts are rendered more uſeful, when they include the ages of the dead, and the diſtempers of which they have died. In this caſe they convey ſome of the moſt important inſtruction, by furniſhing us with the means of aſcertaining the law which governs the waſte of human life, the values of annuities dependent on the continuance of any lives, or any ſurviorſhips between them, and the favourableneſs or unfavourableneſs of different ſituations to the duration of human life. There are but few regiſters of this kind; nor has this ſubject, though ſo intereſting to mankind, ever engaged much attention till lately. The firſt bills containing the ages of the dead were thoſe for the town of Breſlaw in Silcſia. It is well known what uſe has been made of theſe by Dr. Halley, and after him by De Moivre. A table of the probabilities of the duration of human life at every age, deduced from them by Dr. Halley, has been publiſhed in the Philoſophical Tranſactions (ſee the Abridgment, vol. iii. p. 669.) and has been inſerted under the article LIFE-*Annuities* in this work; and this is the firſt table of this ſort that has been ever publiſhed. Since the publication of this table, ſimilar bills have been eſtabliſhed in a few towns of this kingdom; and particularly in London (in the year 1728), and at Northampton, in 1735.

Two improvements of theſe regiſters have been propoſed: the firſt is, that the ſexes of all that die in every period

of life ſhould be ſpecified in them, under the denominations of *boys*, *married men*, *widowers*, and *bachelors*; and of *girls*, *married women*, *widows*, and *virgins*. The ſecond is, that they ſhould ſpecify the numbers of both ſexes dying of every diſtemper in every month, and at every age. See the end of the fourth eſſay in Dr. Price's Treatiſe on Reverſionary Payments. Regiſters of *mortality* thus improved, when compared with records of the ſeaſons, and with the circumſtances that diſcriminate different ſituations, might contribute greatly to the increaſe of medical knowledge; and they would afford the neceſſary *data* for determining the difference between the duration of human life among males and females; for ſuch a difference there certainly is, much in favour of females, as will appear from the following facts; in addition to thoſe which have been already recited under the article MARRIAGE, which the reader is deſired to conſult.

At Northampton, though more males are born than females, and nearly the ſame number die; yet the number of living *females* appeared, by an account taken in 1746, to be greater than the number of males, in the proportion of 2301 to 1770, or 39 to 30.

At Berlin it appeared, from an accurate account which was taken of the inhabitants in 1747, that the number of *female* citizens exceeded the number of *male* citizens in the proportion of 459 to 391. And yet out of this ſmaller number of males, more had died for twenty years preceding 1751, in the proportion of 19 to 17.

At Edinburgh, in 1743, the number of *females* was to the number of *males*, as 4 to 3. (See Maitland's Hiſtory of Edinburgh, p. 220.) But the females that died annually from 1749 to 1758, were to the males in no higher proportion than 3¼ to 3.

He that will take the pains to examine the accounts in Phil. Tranſ. abr. vol. viii. part iv. p. 46, &c. referred to under MARRIAGE, will find, that though in the towns there enumerated, the proportion of males and females born is no higher than 19 to 18, yet the proportion of boys and girls that die is 8 to 7; and that, in particular, the *ſtill-born* and *chryſom* males are to the ſtill-born and chryſom females as 3 to 2. See MARRIAGE.

In thirty-nine parishes of the diſtrict of Vaud in Switzerland, the number of *males* that died during ten years before 1766, was 81703 of females 81673 of whom the numbers that died under one year of age were 1817 *males*, and 1305 *females*; and under ten years of age 3099 *males*, and 2598 *females*. In the beginning of life, therefore, and before any emigrations can take place, the rate of mortality among males appears to be greater than among females. And this is rendered yet more certain by the following accounts. At Vevey, in the diſtrict of Vaud, juſt mentioned, there died in the courſe of twenty years, ended at 1764, in the firſt month after birth of males 135 to 89 females; and in the firſt year 225 to 162. To the ſame effect, it appears from a table given by Suſmilch, in his Gottliche Ordnung, vol. ii. p. 317, that in Berlin 203 males die in the firſt month, and but 168 females; and in the firſt year, 489 to 395; and alſo, from a table of Struyck's, that in Holland 396 *males* die in the firſt year to 366 *females*.

The authorities for the facts here mentioned, and much more on this ſubject, may be found in the fourth eſſay in Dr. Price's Treatiſe on Reverſionary Payments, and in the ſupplement, at the end of that treatiſe.

We ſhall here only add the following table, taken from a memoir of Mr. Wargentin's, publiſhed in the collection of the Memoirs of the Royal Academy of Sciences at Stockholm, printed at Paris in 1772.

In all Sweden for nine years, ended in 1763, the proportion of females to males that died out of a given number living, was

Under the age of one year		—	1000 to	1099

Regiſters of *mortality* on the improved plan before mentioned, were eſtabliſhed in 1772 at Cheſter, and alſo in 1773, at Warrington in Lancaſhire; and they are ſo comprehenſive and correct, that there is reaſon to expect they will afford much inſtruction on the ſubject of human *mortality*, and the values of lives.

But the country moſt diſtinguiſhed in this reſpect is Sweden; for in that kingdom exact accounts are taken of the births, marriages, and burials, and of the numbers of both ſexes that die at all ages in every town and diſtrict; and alſo, at the end of every period of five years, of the numbers living at every age; and at Stockholm a ſociety is eſtabliſhed, whoſe buſineſs it is to ſuperintend and regulate the enumerations, and to collect from the different parts of the kingdom the regiſters, in order to digeſt them into tables of obſervations. Theſe regulations were begun in Sweden in 1755; and tables, containing the reſult of them from 1755 to 1763, have been publiſhed in Mr. Wargentin's memoir juſt referred to, and the moſt material parts of them may be found in an eſſay by Dr. Price on the Difference between the Duration of Human Life in Towns and in Country Parishes, printed in the ſixty-fifth volume of the Philoſophical Tranſactions, part ii.

In the fourth eſſay in Dr. Price's Treatiſe on Reverſionary Payments and Life-Annuities, the following account is given of the principles on which tables of obſervation are formed from regiſters of *mortality*; and of the proper method of forming them, ſo as to render them juſt repreſentations of the number of inhabitants, and the probabilities of the duration of human life in a town or country.

In every place which juſt ſupports itſelf in the number of its inhabitants, without any recruits from other places; or where, for a courſe of years, there has been no increaſe or decreaſe, the number of perſons dying every year at any particular age, and above it, muſt be equal to the number of the living at that age. The number, for example, dying every year, at all ages, from the *beginning* to the utmoſt *extremity* of life, muſt, in ſuch a ſituation, be juſt equal to the whole number *born* every year. And for the ſame reaſon, the number dying every year at *one* year of age and upwards; at *two* years of age and upwards; at *three* and upwards, and ſo on, muſt be equal to the numbers that attain to thoſe ages every year; or, which is the ſame, to the numbers of the living at thoſe ages. It is obvious, that unleſs this happens, the number of inhabitants cannot remain the ſame. If the former number is greater than the latter, the inhabitants muſt *decreaſe*; if leſs, they muſt *increaſe*. From this obſervation it follows, that in a town or country, where there is no increaſe or decreaſe, bills of *mortality* which give the ages at which all die, will ſhew the exact number of inhabitants; and alſo the exact law, according to which human life waſtes in that town or country.

In order to find the number of inhabitants; the mean numbers dying annually, at every particular age and upwards, muſt be taken as given by the bills, and placed under one another in the order of the ſecond column of the following tables. Theſe numbers will, it has appeared, be the numbers of the living at 1, 2, 3, &c. years of age; and, conſequently, the ſum, diminiſhed by half the number born annually, will be the whole number of inhabitants.

This ſubtraction is neceſſary for the following reaſon. In a table formed in the manner here directed, it is ſuppoſed, that the numbers in the ſecond column are all living together at the beginning of every year. Thus: the number in the *ſecond* column oppoſite to 0 in the *firſt* column, the table ſuppoſes to be all juſt born together on the firſt day of the year. The number, likewiſe, oppoſite to 1, it ſuppoſes to attain to one year of age juſt at the ſame time that the former number is born. And the like is true of every number in the ſecond column. During the courſe of the year, as many will die at all ages as were born at the beginning of the year; and, conſequently, there will be an exceſs of the number alive at the beginning of the year, above the number alive at the end of the year, equal to the whole number of the annual births; and the true number conſtantly alive together, is the arithmetical mean between theſe two numbers; or, agreeably to the rule here given, the *ſum* of the numbers in the ſecond column of the table, leſſened by *half* the number of annual births.

In ſuch a ſeries of numbers, the exceſs of each number above that which immediately follows it, will be the number dying every year, out of the particular number alive at the beginning of the year; and theſe exceſſes ſet down regularly as in the third column of the table to which we have referred, will ſhew the different rates at which human life waſtes through all its different periods, and the different probabilities of life at all particular ages.

It muſt be remembered, that what has been now ſaid goes on the ſuppoſition, that the place whoſe bills of *mortality* are given, ſupports itſelf, by procreation only, in the number of its inhabitants. In towns this very ſeldom happens, on account of the luxury and debauchery which generally prevail in them. They are, therefore, commonly kept up by a conſtant acceſſion of ſtrangers, who remove to them from country parithes and villages. In theſe circumſtances, in order to find the true number of inhabitants, and probabilities of life, from bills of *mortality* containing an account of the ages at which all die; it is neceſſary, that the proportion of the annual births to the annual ſettlers ſhould be known, and alſo the period of life at which the latter remove. Both theſe particulars may be diſcovered in the following method.

If for a courſe of years there has been no ſenſible increaſe or decreaſe in a place, the number of annual ſettlers will be equal to the exceſs of the annual burials above the annual births. If there is an *increaſe*, it will be *greater* than this exceſs. If there is a *decreaſe*, it will be *leſs*.

The period of life at which theſe ſettlers remove, will appear in the bills by an increaſe in the number of deaths at that period and beyond it. Thus, in the London bills, the number of deaths, between 20 and 30, is generally above double; and between 30 and 40, near triple the number of deaths between 10 and 20; and the true account of this is, that from the age of 18 or 20, to 35 or 40, there is an afflux of people every year to London from the country, which occaſions a great increaſe in the number of inhabitants as theſe ages; and, conſequently, raiſes the deaths for all ages *above* 20, conſiderably above their due proportion, when compared with the number of deaths *before* 20. This is obſervable in all the bills of *mortality* for towns with which we are acquainted, not excepting even the Breſlaw bills. Dr. Halley takes notice, that theſe bills gave the number of deaths, between 10 and 20, too ſmall. This he conſidered as an irregularity in them, owing to chance; and, therefore, in forming his table of obſervations, he took the liberty to *vary* to correct it, ſo to render the proportion of thoſe who die to the living in this diviſion of life, nearly the ſame with the proportion which, he ſays, he had been *informed* die annually of the young lads in Chriſt-Church Hoſpital. But the truth is, that this irregularity in the bills was derived from the cauſe we have juſt aſſigned. During the five years for which the Breſlaw bills are given by Dr. Halley, the births did, indeed, a little exceed the burials; but it appears, that this was the effect of ſome peculiar cauſes that happened to operate juſt at that time; for, during a complete century from 1633 to 1734, the annual medium of *births* was 1089 (ſee Dr. Short's Comparative Hiſtory, p. 63), and of burials 1256. This town, therefore, muſt have been all along kept up by a number of yearly recruits from other places, equal to about *a fourth* part of the yearly births.

It appears from the account in the Philoſophical Tranſactions (Abridgment, vol. vii. N° 380, p. 46, &c.) that from 1717 to 1725, the annual medium of births at Breſlaw was 1252, of burials 1507; and alſo, that much the greateſt part of the births died under ten years of age. From a table in Sufmilch's Works, vol. i. p. 38, it appears, that, in reality, the greater part of all that die in this town are children under five years of age.

What has been now obſerved, concerning the period of life at which people remove from the country to ſettle in towns, would appear ſufficiently probable, were there no ſuch evidence for it as has been mentioned; for it might be well reckoned, that theſe people in general muſt be ſingle perſons in the beginning of mature life, who, not having yet obtained ſettlements in the places where they were born, migrate to towns in queſt of employments.

Having premiſed theſe obſervations, it will be proper next to endeavour to explain diſtinctly the effect which theſe acceſſions to towns muſt have on tables of obſervation formed from their bills of *mortality*. This is a ſubject proper to be inſiſted on, becauſe miſtakes have been committed about it; and becauſe alſo the diſcuſſion of it is neceſſary to ſhew, how near to truth the values of lives come as deduced from ſuch tables.

The following general rule may be given on this ſubject. If a place has, for a courſe of years, been maintained in a ſtate nearly ſtationary, as to number of inhabitants, by recruits coming in every year, to prevent the decreaſe that would ariſe from the exceſs of the burials above the births; a table formed on the principle, "That the number dying annually, after every particular age, is equal "to the number living at that age," will give the number of inhabitants, and the probabilities of life, too *great*, for all ages preceding that at which the recruits ceaſe; and after this it will give them *right*. If the acceſſions are ſo great as to cauſe an *increaſe* in the place, ſuch a table will give the number of inhabitants, and the probabilities of life, too *little*, after the age at which the acceſſions ceaſe; and too great, if there is a decreaſe. *Before* that age it will in *both* caſes give them too great; but moſt conſiderably ſo in the former caſe, or when there is an increaſe.

Agreeably to theſe obſervations, if a place increaſes, not in conſequence of acceſſions from other places, but of a conſtant exceſs of the births above the deaths; a table, conſtructed on the principle that has been mentioned, will give the probabilities of life too low through the *whole extent* of life; becauſe, in ſuch circumſtances, the number of *deaths* in the *firſt* ſtages of life muſt be too great, in compariſon of the number of deaths in the *latter* ſtages; and more or leſs ſo, as the *increaſe* is more or leſs rapid. The contrary, in all reſpects, takes place where there is a decreaſe, ariſing from the exceſs of the *deaths* above the *births*.

For example. Let us ſuppoſe, that 244 of thoſe born in a town, attain annually to 20 years of age; and that 250 more, all likewiſe twenty years of age, come into it annually from other places; in conſequence of which, it has, for a courſe of years, been juſt maintained in the number of its inhabitants, without any ſenſible increaſe or decreaſe. In theſe circumſtances, the number of the living in the town of the age of 20, will be always 244 *natives* and 250 *ſettlers*, or 494 in all; and, ſince theſe are ſuppoſed all to die in the town, and no more recruits are ſuppoſed to come in, 494 will be likewiſe the number dying annually at 20 and upwards. In the ſame manner it will appear, on theſe ſuppoſitions, that the number of the living, at every age, ſubſequent to 20, will be equal to the number dying annually at that age and above it; and, conſequently, that the number of inhabitants and the decrements of life, for every ſuch age, will be given exactly by the table. But for all ages *before* 20, they will be given much too great. For let 280 of all born in the town, reach 10; in this caſe, 280 will be the true number of the living in the town at the age of 10; and the recruits not coming in till 20, the number given by the bills, as dying between 10 and 20, will be the true number dying annually of the living in this diviſion of life. Let this number be 36; and it will follow, that the table ought to make the numbers of the living at the ages between 10 and 20, a ſeries of decreaſing means between 280 and (280 diminiſhed by 36, or) 244. But in forming the table on the principle juſt mentioned, 250 (the number above 20 dying annually *in* the town who were not born in it) will be added to each number in this ſeries; and, therefore, the table will give the numbers of the living, and the probabilities of life in this diviſion of life, almoſt twice as great as they really are. This obſervation, it is manifeſt, may be applied to *all* the ages under 20.

It is neceſſary to add, that ſuch a table will give the number of inhabitants, and the probabilities of life equally wrong before 20, whether the recruits all come in at 20, agreeably to the ſuppoſition juſt made, or only *begin* then to come in. In this laſt caſe, the table will give the number of inhabitants, and probabilities of life, too great throughout the whole extent of life, if the recruits come in at all ages above 20. But if they ceaſe at any particular age, it will give them right only from that age; and before, it will err all along on the ſide of exceſs; but leſs conſiderably between 20 and that age, than before 20. For example: if, of the 250 ſuppoſed to come in at 20, only 150 then come in, and the reſt at 30; the number of the living will be given 100 too high, at every age between 20 and 30; but, as juſt ſhewn, they will be given 250 too high at every age before 20. In general, therefore, the number of the living at any particular age, muſt be given by the ſuppoſed table, as many too great as there are annual ſettlers *after* that age; and, if theſe ſettlers come in at all ages indiſcriminately, during any certain interval of life, the number of inhabitants and the probabilities of life will be continually growing leſs and leſs wrong, the nearer any age is to the end of that interval. Theſe obſervations prove, that tables of obſervation formed in the common way, from bills of *mortality* for places where there is an exceſs of the burials above the births, muſt be erroneous, for a great part of the duration of life, in proportion to the degree of that exceſs. They ſhew likewiſe at what parts of life the errors in ſuch tables are moſt conſiderable, and how they may be in a great meaſure corrected.

All this ſhall be exemplified in the particular caſe of London.

The number of deaths between the ages of 10 and 20, is always ſo ſmall in the London bills, that it ſeems certain few recruits come to London under 20; or, at leaſt, not ſo many as before this age are ſent out for education to ſchools and univerſities. After 20, great numbers come

in

in till 30, and some, perhaps, till 40 or 50. But at every age after 50, it is probable, that more retire from London than come to it. The London tables of observation, therefore, being formed on the principle already mentioned, cannot give the probabilities of life right till 40. Between 30 and 40 they must be a little too high; but more so between 20 and 30; and most of all before 20. It follows also, that these tables must give the number of inhabitants in London much too great.

The first of the following tables is formed in the manner here explained, from the London bills for ten years, from 1759 to 1768; and adapted to a 1000 born as a *radix*. The sum of the numbers in the second column, diminished by half the number born, is 25,757. According to this table, then, for every 1000 deaths in London, there are 25½ as many inhabitants; or, in other words, the expectation of a child just born is 25½; and the inhabitants are to the annual burials as 25½ to 1. But it has appeared, that the numbers in the second column, being given on the supposition, that all those who die in London were born there, must be too great; and we have from hence a demonstration, that the probabilities of life are given in the common tables, of London observations, too high, for, at least, the first 30 years of life; and also, that the number of inhabitants in London must be *less* than 25½, multiplied by the annual burials. The common tables, therefore, of London observations undoubtedly need correction, as Mr. Simpson suggested, and in some measure performed; though too imperfectly, and without going upon any fixt principles, or shewing particularly, how tables of observation ought to be formed, and how far in different circumstances, and at different ages, they are to be depended on. The way of doing this, and, in general, the right method of forming genuine tables of observation for towns, may be learnt from the following rules.

"From the sum of all that die annually, *after* any given "age, subtract the number of annual settlers *after* that "age; and the remainder will be the number of the "living *at* the given age."

This rule can want no explication or proof, after what has been already said.

If, therefore, the number of annual settlers in a town at every age could be ascertained, a perfect table of observations might be formed for that town, from bills of *mortality*, containing an account of the ages at which all die in it. But no more can be learnt in this instance, from any bills than the whole number of annual *settlers*, and the general division of life in which they enter. This, however, may be sufficient to enable us to form tables that shall be tolerably exact. For instance: suppose the *annual deaths* in a town which has not increased or decreased, to have been for many years, in the proportion of 4 to 3, to the *annual births*. It will hence follow, that ¼ of the persons who die in such a town are *settlers*, or *emigrants* from other places, and not *natives*; and the sudden increase in the deaths after 20, will also shew, agreeably to what was before observed, that they enter after this age. In forming, therefore, a table for such a town, a *quarter* of all that die at all ages throughout the whole extent of life, must be deducted from the sum of all that die after every given age before 20; and the remainder will be the true number living at that given age. And if, at 20, and every age above it, this deduction is omitted, or the number of the living at every such age is taken the same with the sum of all that die after it, the result will be (supposing *most* of the settlers to come in before 30, and *all* before 40) a table exact till 20; too high between 20 and 30; but nearly right for some years before 40; and after 40 exact again. Such a table, it is evident, will be the same with the table last described at all ages above 20, and different from it only under 20. It is evident also that, on account of its giving the probabilities of life too great for some years after 20, the number of inhabitants deduced from it may be depended on as somewhat greater than the truth; and more or less so, as the annual recruits enter in general later or sooner after 20.

Let us now consider what the result of these remarks will be, when applied particularly to the London bills. It must be here first observed, that, at least one *quarter* of all that die in London are supplies or *settlers* from the country, and not *natives*. The medium of annual burials for ten years, from 1759 to 1768, was 23,936; of births, 15,710. The excess is 8246, or near a *third* of the burials. The same excess, during ten years, before 1750, was 10,500, or near *half* the burials. London was then *increasing*. For the last 12 or 15 years it has been *increasing*. This excess, therefore, agreeably to the foregoing observations, was then *greater* than the number of annual settlers, and it is now *less*. It is, however, here supposed, that the number of annual settlers is now no more than a *quarter* of the annual burials, in order to allow for more omissions in the births than the burials; and also, in order to be more sure of obtaining results that shall not exceed the truth.

Of every thousand then who die in London, only 750 are *natives*, and 250 are recruits, who come to it after 18 or 20 years of age; and, consequently, in order to obtain from the bills a more correct table than the first of the following tables, 250 must be subtracted from every one of the numbers in the second column till 20; and the numbers in the third column must be kept the same, the bills always giving these right. After 20, the table is to be continued unaltered; and the result will be, a table which will give the numbers of the living at all ages in London much nearer the truth, but still somewhat too high. Such is the second of the following tables. The sum of all the numbers in the second column of this table, diminished by 500, is 20,750. For every 1000 deaths, therefore, in London, there are, according to this table, 20,750 living persons in it; or for every single death, 20¾ inhabitants. It was before shewn, that the number of inhabitants in London could not be so great as 25 times ½ the deaths. It now appears (since the numbers in the second column of this table are too high) that the number of inhabitants in London cannot be so great as even 20 times ½ the deaths. And this is a conclusion which every one, who will bestow due attention on what has been said, will find himself forced to receive. It will not be amiss, however, to confirm it by the following fact, the knowledge of which is derived from the particular enquiry and information of Mr. Harris, the late ingenious master of the Royal Mathematical School in Christ-Church Hospital. The average of lads in this school has, for thirty years past, been 831. They are admitted at all ages between seven and eleven; and few stay beyond fifteen: they are, therefore, in general, lads between the ages of eight and fifteen. They have better accommodations than it can be supposed children commonly have; and about three hundred of them have the particular advantage of being educated in the country. In such circumstances it may be well reckoned, that the proportion of children dying annually, must be less than the general proportion of children dying annually at the same ages in London. The fact is, that, for the last thirty years, 212 have died annually, or *one* in 70.

According to Table II. *one* in 74 dies between 10 and 20, and *one* in 70 between 8 and 16. That table, therefore, probably, gives the decrements of life in London, at these ages, too little, and the numbers of the living too great: and, if this is true of these ages, it must be true of all other ages *under* 20; and it follows demonstrably, in conformity to what was before shewn, that more people settle in London after 20, than the ¼ above supposed; and that from 20 to at least 30 or 35, the numbers of the living are given too great, in proportion to the decrements of life.

In this table the numbers in the second column are doubled at 20, agreeably to what really happens in London; and the sum of the numbers in this column diminished by half the whole number of deaths, gives the *expectation* of life, not of a child just born, as in other tables, but of all the inhabitants of London at the time they enter it, whether that be at birth, or at 20 years of age. The *expectations*, therefore, and the *values* of London lives under 20, cannot be calculated from this table. But it may be very easily fitted for this purpose, by finding the number of births which, according to the given decrements of life, will leave 404 alive at 20; and then adapting the intermediate numbers in such a manner to this radix, as to preserve all along the number of the living, in the same proportion to the numbers of the dead. This is done in the third of the following tables; and this table may be recommended as better adapted to the present state of London than any other table. The values of lives, however, deduced from it, are in general nearly the same with those deduced by Mr. Simpson from the London bills, as they stood forty years ago; the main difference is, that after 52, and in old age, this table gives them somewhat lower than Mr. Simpson's table.

For the method of applying these observations in determining the number of inhabitants in London, &c. see EXPECTATION of *life*.

Under the article EXPECTATION, an account has been given of the difference between the rate of human *mortality* in great towns and in country parishes and villages. The fourth and fifth of the following tables, compared with the two last, will give a more distinct and full view of this difference.

TABLE

TABLE I.

Shewing the Probabilities of Life in London, on the fuppofition, that all who die in London were born there. Formed from the Bills, for 10 years, from 1759 to 1768.

This writer has alſo given the bills of the pariſh of St. Peter's at Berlin, for 24 years; and a table formed from them, agrees nearly with this.

MORTAR, or MORTER, in *Architecture*, a compoſition of lime, ſand, &c. mixed up with water; ſerving, as a cement to bind the ſtones, &c. of a building.

The ancients had a kind of *mortar* ſo very hard and binding, that, after ſo long a duration as to this time, it is next to impoſſible to ſeparate the parts of ſome of their buildings; though there are ſome who aſcribe that exceſſive ſtrength to time, and the influence of certain properties in the air, which is, indeed, found to harden ſome bodies very ſurpriſingly.

The lime uſed in the ancient *mortar* is ſaid to have been burnt from the hardeſt ſtones, or often from fragments of marble.

De Lorme obſerves, that the beſt *mortar* is that made of pozzolana for ſand; adding, that this penetrates black flints, and turns them white. See POZZOLANA, and *Puteolanus* PULVIS.

Mr. Worlidge obſerves, that fine ſand makes weak *mortar*, and that the larger the ſand the ſtronger the *mortar*. He therefore adviſes, that the ſand be waſhed before it is mixed; and adds, that ditty water weakens the *mortar* conſiderably.

Wolfius obſerves, that the ſand ſhould be dry and ſharp, ſo as to prick the hands when rubbed; yet not earthy, ſo as to ſoul the water it is waſhed in.

Vitruvius obſerves, that foſſile ſands dry ſooner than thoſe taken out of rivers. Whence he adds, the latter is fitted for the inſides, the former for the outſides of a building. He ſubjoins, that foſſile ſand, lying long in the air, becomes earthy. Palladio takes notice, that of all ſands white ones are the worſt; and the reaſon is owing to their want of aſperity.

The proportion of lime and ſand in our common *mortar* is extremely variable: Vitruvius preſcribes three parts of pit-ſand, and two of river ſand, to one of lime; but the quantity of ſand here ſeems to be too great.

The proportion moſt commonly uſed in the mixing of lime and ſand is to a buſhel of lime a buſhel and a half of ſand, i. e. two parts of lime and three of ſand; though the common *mortar*, in and about London, has more ſand in it than according to this proportion. The improvement of *mortar* is certainly an object of great importance: and different ſchemes have been ſuggeſted for giving it that degree of durability for which the *mortar* uſed by the ancients is ſo juſtly celebrated.

Mr. Doſſie, in the ſecond volume of the Memoirs of Agriculture, p. 20, &c. gives the following method of making *mortar* impenetrable to moiſture, acquiring great hardneſs and exceedingly durable, ſimilar to that uſed by the ancients, which was diſcovered by a gentleman at Neufchatel: take of unſlaked lime and of fine ſand, in the proportion of one part of the lime to three parts of the ſand, as much as a labourer can well manage at once; and then adding water gradually, mix the whole well together, with a trowel, till it be reduced to the conſiſtence of *mortar*. Apply it immediately, while it is hot, to the purpoſe, either of *mortar*, as a cement to brick or ſtone, or of plaſter for the ſurface of any building. It will then ferment for ſome days in drier places, and afterwards gradually concrete, or ſet, and become hard: but in a moiſt place it will continue ſoft for three weeks or more; though it will, at length, attain a firm conſiſtence, even if water have ſuch acceſs to it ſo as to keep the ſurface wet the whole time. After this it will acquire a ſtone-like hardneſs, and reſiſt all moiſture. The perfection of this *mortar* depends on the ingredients being thoroughly blended together; and the mixture's being applied immediately after to the place where it is wanted. The lime for this *mortar* muſt be made of lime-ſtone, ſhells, or marble; and the ſtronger it is, the better the *mortar* will be: beſides, the lime ſhould be carefully kept from the acceſs of air or wet; otherwiſe, by attracting moiſture, it will loſe proportionably that power of acting on the ſand, by which their incorporation is produced. It is proper alſo to exclude the ſun and wind from the *mortar*, for ſome days after it is applied; that the drying too faſt may not prevent the due continuance of the fermentation, which is neceſſary for the action of the lime on the ſand. When a very great hardneſs and firmneſs are required in this *mortar*, the uſing of ſkimmed milk inſtead of water, either wholly or in part, will produce the deſired effect, and render the *mortar* extremely tenacious and durable.

M. Loriot's *mortar*, the method of making which was announced by order of his majeſty, at Paris, in 1774, is made in the following manner: take one part of brick-duſt finely ſifted, two parts of fine river ſand ſcreened, and as much old ſlaked lime as may be ſufficient to form *mortar* with water, in the uſual method, but ſo wet as to ſerve for the ſlaking of as much powdered quick-lime as amounts to one fourth of the whole quantity of brick-duſt and ſand. When the materials are well mixed, employ

employ the compoſition quickly, as the leaſt delay may render the application of it imperfect or impoſſible. Another method of making this compoſition is to make a mixture of the dry materials; i. e. of the ſand, brick-duſt, and powdered quick-lime, in the preſcribed proportion; which mixture may be put in ſacks, each containing a quantity ſufficient for one or two troughs of *mortar*. The above mentioned old ſlaked lime and water being prepared apart, the mixture is to be made, in the manner of plaſter, at the inſtant when it is wanted, and is to be well chaſed with the trowel. With reſpect to this method, Dr. Higgins obſerves, that M. Loriot corrects the bad quality of the old and effete lime, which conſtitutes the baſis of his *mortar*, and which has regained a part of the fixed air, that had been expelled from it, by the addition of freſh and non-effervefcent lime, ſtiſtly added to it, at the time of uſing the compoſition, which muſt undoubtedly improve the imperfect maſs. And he adds, that when an ignorant artiſt makes *mortar* with whiting inſtead of lime, he can mend it conſiderably by adding lime to it; but his *mortar* will ſtill be defective, in compariſon with the beſt that may be made, by reaſon of the old ſlaked lime or whiting: this on repeated trials he has found to be the true ſtate of the caſe. Dr. Higgins has made a variety of experiments, in conſequence of the modern diſcoveries relating to fixed air, for the purpoſe of improving the *mortar* uſed in our buildings. According to this author, the perfection of lime, prepared for the purpoſe of making *mortar*, conſiſts chiefly in its being totally deprived of its fixed air. On examining ſeveral ſpecimens of the lime commonly uſed in building, he found that it is ſeldom or never ſufficiently burned; for they all effervefced, and yielded more or leſs fixed air, on the addition of an acid, and ſlaked ſlowly, in compariſon with well burned lime. Dr. Higgins alſo relates ſome experiments, which ſhew how very quickly lime imbibes fixed air from the atmoſphere; on its expoſure to which, it by degrees loſes thoſe characters which chiefly diſtinguiſh it from mere lime-ſtone or powdered chalk; by ſoon attracting from thence that very principle, to the abſence of which it owes its uſeful quality as a cement, and which had before been expelled from it in the burning. Hence he concludes, that, as lime owes its excellence to the expulſion of fixed air from it in the burning, it ſhould be uſed as ſoon as poſſible after it is made, and guarded from expoſure to the air, as much as poſſible, before it is uſed. It is no wonder, therefore, he ſays, that the London *mortar* is bad, if the imperfection of it depended ſolely on the badneſs of the lime; ſince the lime employed in it is not only bad when it comes freſh from the kiln, becauſe it is inſufficiently burned and the air has acceſs to it, but becomes worſe before it is uſed, by the diſtance and mode of its conveyance, and when ſlaked is as widely different from good lime, as it is from powdered chalk. For a ſimilar reaſon, every other cauſe, which tends to reſtore to the lime, the fixed air, of which it had been deprived in the burning, muſt deprave it. It muſt receive this kind of injury, for inſtance, from the water, ſo largely uſed, firſt in ſlaking the lime, and afterwards in making it into *mortar*; if that water contains fixed air, from which few waters are perfectly free, and which will greedily be attracted by the lime. The injury ariſing from this cauſe is prevented by the ſubſtitution of lime-water, ſo far as may be practicable or convenient.

From other experiments, made with a view of aſcertaining the beſt relative proportions of lime, ſand, and water, in the making of *mortar*, it appeared, that thoſe ſpecimens were the beſt which contained one part of lime in ſeven of the ſand; for thoſe which contained leſs lime, and were too ſhort whilſt freſh, were more eaſily cut and broke, and were pervious to water; and thoſe which contained more lime, although they were cloſer in grain, did not harden ſo ſoon or to ſo great a degree, even when they eſcaped cracking by lying in the ſhade to dry ſlowly. It appeared farther, that *mortar*, which is to be uſed where it muſt dry quickly, ought to be made as ſtiff as the purpoſe will admit, or, with the ſmalleſt practicable quantity of water, and that *mortar* will not crack, although the lime be uſed in exceſſive quantity, provided it be made ſtiffer, or to a thicker conſiſtence than *mortar* uſually is.

Dr. Higgins has alſo ſhewn, that though the ſetting of *mortar*, as it is called by the workmen, chiefly depends on the exſiccation of it, yet its induration, or its acquiring a ſtony hardneſs, is not cauſed by its drying, as has been ſuppoſed, but is principally owing to its abſorption of fixed air from the atmoſphere, and is promoted in proportion as it acquires this principle; the acceſſion of which is indiſpenſably neceſſary to the induration of calcareous cements. In order to the greateſt induration of *mortar*, therefore, it muſt be ſuffered to dry gently and ſet; the exſiccation muſt be effected by temperate air, and not accelerated by the heat of the ſun or fire; it muſt not be wetted ſoon after it ſets; and afterwards it ought to be protected from wet as much as poſſible, until it is completely indurated; the entry of acidulous gas muſt be prevented as much as poſſible, until the *mortar* is finally placed and quieſcent; and then it muſt be as freely expoſed to the open air, as the work will admit, in order to ſupply acidulous gas, and enable it ſooner to ſuſtain the trials to which *mortar* is expoſed in cementitious buildings, and incruſtations.

Dr. Higgins has alſo inquired into the nature of the beſt ſand or gravel for *mortar*, and into the effects produced by bone aſhes, plaſter powder, charcoal, ſulphur, &c. and he deduces great advantages from the addition of bone aſhes, in various proportions, according to the nature of the work for which the compoſition is intended.

This author deſcribes a water cement or ſtucco, of his own invention, for incruſtations internal and external, exceeding, as he ſays, Portland ſtone in hardneſs, for which he obtained his majeſty's letters patent in 1779. As for the materials of which this is made; driſt ſand, or quarry ſand, or, as it is commonly called, pit ſand, conſiſting chiefly of hard quartoſe flat-faced grains, with ſharp angles, the moſt free from clay, ſalts, and calcareous, gypſeous, or other grains, leſs durable than quartz, containing the ſmalleſt quantity of pyrites, or heavy metallic matter, inſeparable by waſhing, and admitting the leaſt diminution in bulk by waſhing, is to be preferred to any other. The ſand is to be ſifted in ſtreaming clear water, through a ſieve which ſhall give paſſage to all ſuch grains as do not exceed one ſixteenth of an inch in diameter: and the ſtream of water and ſifting are to be ſo regulated, that all the ſand, which is much finer than the Lynn ſand, together with clay and other matter, ſpecifically lighter than ſand, may be waſhed away with the ſtream; whilſt the purer and coarſer ſand, which paſſes through the ſieve, ſubſides in a convenient receptacle, and whilſt the coarſe rubbiſh and ſhingle remain on the ſieve to be rejected. The ſubſiding ſand is then waſhed in clean ſtreaming water, through a finer ſieve, ſo as to be further cleanſed and ſorted into two parcels, a coarſer, which will remain in the ſieve which is to give paſſage to ſuch grains of ſand only as are leſs than one thirtieth of an inch in diameter, and which is to be ſaved apart under the name of coarſe ſand: and a finer, which will paſs through the ſieve and ſubſide in the water, and which is to be ſaved apart under the name of fine ſand. Theſe are to be dried ſeparately, either in the ſun, or on a clean iron plate ſet on a convenient ſurface, in the manner of a ſand heat. Let the lime be choſen, which is ſtone-lime, which heats the moſt in ſlaking, and ſlakes the quickeſt when duly watered; which is the freſheſt made and moſt cloſely kept; which diſſolves in diſtilled vinegar with the leaſt effervefcence, and leaves the ſmalleſt reſidue inſoluble, and in this reſidue the ſmalleſt quantity of clay, gypſum, or martial matter. Let this lime be put in a braſs-wired fine ſieve, to the quantity of fourteen pounds. Let the lime be ſlaked by plunging it in a butt, filled with ſoft water, and raiſing it out quickly and ſuffering it to heat and ſume, and by repeating this plunging and raiſing alternately, and agitating the lime, until it be made to paſs through the ſieve into the water: reject the part of the lime that does not eaſily paſs through the ſieve; and uſe freſh portions of lime, till as many ounces of lime have paſſed through the ſieve, as there are quarts of water in the butt. Let the water, thus impregnated, ſtand in the butt, cloſe covered, until it becomes clear; and, through wooden cocks placed at different heights in the butt, draw off the clear liquor, as faſt and as low as the lime ſubſides, for uſe. This clear liquor is called the cementing liquor. Let fifty-ſix pounds of the foreſaid choſen lime be ſlaked, by gradually ſprinkling on it, and eſpecially on the unſlaked pieces, the cementing liquor, in a cloſe clean place. Let the ſlaked part be immediately ſifted through the fine braſs-wired ſieve. Let the lime which paſſes be uſed inſtantly, or kept in air-tight veſſels, and let the part of the lime which does not paſs through the ſieve be rejected: the other part is called purified lime. Let bone aſh be prepared in the uſual manner by grinding the whiteſt burnt bones; but let it be ſifted to be much finer than the bone aſh commonly ſold for making cupels. Having thus prepared the materials, take fifty-ſix pounds of the coarſe ſand, and forty-two pounds of the fine ſand; mix them on a large plank of hard wood placed horizontally: then ſpread the ſand ſo that it may ſtand to the height of ſix inches, with a flat ſurface on the plank; wet it with the cementing liquor; to the wetted ſand add fourteen pounds of the purified lime, in ſeveral ſucceſſive

ceſſive portions, mixing and beating them up together; then add fourteen pounds of the bone aſh in ſucceſſive portions, mixing and beating all together. This Dr. Higgins calls the water-cement coarſe-grained, which is to be applied in building, pointing, plaſtering, ſtuccoing, &c. obſerving to work it expeditiouſly in all caſes, and in ſtuccoing to lay it on by ſliding the trowel upwards upon it; to wet well the materials uſed with it, or the ground on which it is laid, with the cementing liquor, at the time of laying it on; and to uſe the cementing liquor for moiſtening the cement and facilitating the floating of it.

If a cement of a finer texture be required, take ninety-eight pounds of the fine ſand, wet it with the cementing liquor, and mix it with the purified lime and the bone aſh, as above, with this difference, that fifteen pounds of lime are to be uſed inſtead of fourteen pounds, if the greater part of the ſand be as fine as Lynn ſand. This is called water-cement fine-grained; and is uſed in giving the laſt coating or the finiſh to any work, intended to imitate the finer grained ſtones or ſtucco. For a cheaper and coarſer cement, take of coarſe ſand or ſhingle fifty-ſix pounds, of the foregoing coarſe ſand twenty-eight pounds, and of the finer ſand fourteen pounds; and after mixing and wetting theſe with the cementing liquor, add fourteen pounds, or ſomewhat leſs, of the purified lime, and then as much of the bone aſh, mixing them together. When the cement is required to be white, white ſand, white lime, and the whiteſt bone aſh are to be choſen. Grey ſand, and grey bone aſh, formed of half-burnt bones, are to be choſen to make the cement grey; and any other colour is obtained, either by chuſing coloured ſand, or by the admixture of the neceſſary quantity of coloured talc in powder, or of coloured vitreous or metallic powders, or other durable colouring ingredients, commonly uſed in paint. The water-cement above deſcribed is applicable to forming artificial ſtone, by making alternate layers of the cement and of flint, hard ſtone, or brick, in moulds of the figure of the intended ſtone, and by expoſing the maſſes ſo formed to the open air to harden. When it is required for water fences, two thirds of the bone aſhes are to be omitted, and in its ſtead an equal meaſure of powdered terras is to be uſed. When the cement is required of the fineſt grain, or in a fluid form, ſo that it may be applied with a bruſh, flint powder, or the powder of any quartoſe or hard earthy ſubſtance, may be uſed in the place of ſand, ſo that the powder ſhall not be more than ſix times the weight of the lime, nor leſs than four times its weight. For inſide work, the admixture of hair with the cement is uſeful. Higgins's Exp. and Obſ. on Calcareous Cements, &c. 8vo. 1780, paſſim. See STUCCO.

MORTAR, *mixing and blending of.* M. Felibien obſerves, that the ancient maſons were ſo very ſcrupulous herein, that the Greeks kept ten men conſtantly employed, for a long ſpace of time, to each baſon; this rendered the *mortar* of ſuch prodigious hardneſs, that Vitruvius tells us the pieces of plaſter falling off from old walls ſerved to make tables. The ſame Felibien adds, it is a maxim among old maſons to their labourers, that they ſhould dilute with the ſweat of their brow, i. e. labour it a long time, inſtead of drowning it with water, to have done the ſooner.

Beſides the common *mortar* uſed in laying of ſtones, bricks, &c. there are ſeveral other kinds: as,

MORTAR, *white*, uſed in plaſtering the walls and ceilings, made of ox or cow's hair mixed with lime and water, without any ſand. The common method of making this *mortar* is one buſhel of *hair* to ſix buſhels of lime.

MORTAR *uſed in making water-courſes, ciſterns, &c.* is very hard and durable, being made of lime and hogs-greaſe, ſometimes mixed with the juice of figs, and ſometimes with liquid pitch: and, after application, is waſhed over with linſeed-oil. See BUTON.

For this purpoſe, *mortar* made of terras, pozzolana, tile-duſt, or cinders, is mixed and prepared in the ſame manner as common *mortar*: only that theſe ingredients are mixed with lime, inſtead of ſand, in a due proportion, which is about half and half. The lime ſhould be made of ſhells or *marble*; and in works which are ſometimes dry and ſometimes wet, inſtead of terras, which is very dear, tile-duſt or cinder-duſt may be uſed.

MORTAR *for furnaces, &c.* See LUTE.

MORTAR *for ſun-dials* on walls may be made of lime and ſand, tempered with linſeed-oil; or, for want of that, with ſkimmed milk. This will grow to the hardneſs of a ſtone.

For buildings, one part of waſhed ſoup-aſhes, mixed with another of lime and ſand, make a very durable *mortar*. See CEMENT.

The ſalt-petre workers in France uſing the *mortar* of old buildings for extracting that ſalt, Mr. Petit has thought it worthy a peculiar attention, and has made ſeveral trials, by way of analyſis of *mortar*, to determine whether it really and eſſentially contains nitre in it, or whether it be only ſerviceable in that mixture of ſalts from which nitre is produced.

The common managers of the ſalt-petre works are of opinion, that *mortar* contains in it all the ſalt-petre they procure from it, and that the wood aſhes, and other ſubſtances they uſe with it, only ſerve to abſorb the fat or oily parts, and ſo ſet the ſalt-petre at liberty to ſhoot. This they pretend to affirm upon experience; but they do not conſider that though they can procure ſalt-petre from the rubbiſh or *mortar* without the addition of wood aſhes, yet it is not pure *mortar* that they make their experiments upon, but ſuch as is taken from their own heaps, upon which they always throw all the reſiduum of their former works, and all that liquor which will ſhoot no more cryſtals, but which they call the mother-water of ſalt-petre.

This gentleman, therefore, very properly judged, that to make a regular trial of the *mortar* or rubbiſh alone, he muſt not take it from their ſtores, uſed in the ſalt-petre works, but pick it himſelf from the ruins of old buildings.

The mark the ſalt-petre workers have to know good *mortar* for their purpoſe, is, that it taſtes acrid and ſalt when applied to the tongue; but to this it may be alſo added, that it ought to be of a greyiſh colour, and ſuch as when powdered and ſprinkled upon burning charcoal yields ſome ſparks of fire; and the more ſparks it gives, the better it is for the purpoſe: and another character of the goodneſs is, that theſe well impregnated *mortars* have a certain unctuoſity or fatineſs to the touch, which other kinds have not.

The fineſt of all kinds of *mortar* for ſalt-petre work, is ſuch as is had from the ruins of old buildings in a low ſituation, and out of the way of much ſunſhine; where there has been no great quantity of fire kept, and eſpecially ſuch as has ſerved for the cements of the walls of ſtables, or the like.

Mr. Petit choſe from ſuch a wall twelve pounds of old *mortar*; this he had beat to powder, and poured upon it eighteen pints of water: the whole was then ſet over the fire, and ſtirred from time to time for three or four hours, that the water might be well tinctured from the *mortar*; after this the water was filtered through paper, and was then found to be tinctured to a pale, yellow, tranſparent bitter, and ſomewhat acrid to the taſte.

The impregnation may be made without heat, by only ſtirring the *mortar* about for nine or ten days in cold water, and a quantity of the ſalt taken up will be according to the goodneſs of the *mortar* and the quantity of water employed. The common ſpecific gravity of this liquor to water, is as 32 to 31, or thereabouts. Mr. Petit having procured the tincture of fifty pounds of *mortar*, by ſeveral impregnations, in ſeventy-two French pints of water, evaporated it ſo far till it appeared highly charged with ſaline particles, taſting very acrid and bitter, and being of a brownith red colour; and its ſpecific gravity was in this ſtate to water as 4 to 3, there being more in quantity than about four pints. This was ſtill limpid and of a duſky colour, and was afterwards evaporated over a gentle fire, to the conſiſtence of an extract, which as it cooled became much thicker and firmer, reſembling butter. This being left open to the air, ſoon relented into a liquor of the conſiſtence of a ſyrup: its ſpecific gravity was now to water as 5 to 3; but in leaving it open to the air, it continually attracted freſh humidity, and became leſs ſpecifically heavy. Experiments made with this extract ſucceeded in the following manner.

1. It turned the common blue paper to a fine deep red. The impregnations in water uninſpiſſated do this alſo in different degrees according to their ſtrength.

2. Mixed in equal quantities with ſpirit of nitre and with ſpirit of ſea ſalt, it made no effervеſcence or alteration in either.

3. A leaf of gold being put into the mixture of this impregnation with ſpirit of nitre was immediately diſſolved, and in an hour or two afterwards the liquor was much clearer than before.

A leaf of gold being put into the mixture of this impregnation and ſpirit of ſea ſalt, was in the ſame manner diſſolved in a few minutes. It is generally ſuppoſed indeed that the ſpirit of ſalt alone will diſſolve gold, but there ſeems an error in this founded on the inaccuracy of the preparation of ſuch ſpirit of ſalt; for Meſſrs. Geoffroy and Boulduc have at different times produced before the French Academy ſpirit of ſalt carefully prepared by themſelves, which would not at all diſſolve gold, not even with the aſſiſtance of heat; even ſuch ſpirit of ſalt would however be made to diſſolve gold, by

mixing

mixing this impregnation with it: so that it has the power of diſſolving gold in a great degree.

4. A leaf of ſilver being diſſolved in ſpirit of nitre, and this impregnation of *mortar* added to the ſolution, the whole became turbid, and a precipitation happened, part of the matter being thrown to the bottom, and part remaining ſuſpended in form of a white cloud, which kept its place without falling.

5. The impregnation being mixed in equal quantities with oil of vitriol formed a coagulum, and made a great effervescence, with copious red vapours, and a ſtrong ſmell of aqua fortis; and theſe vapours appeared at any time, on ſtirring the mixture for ſeveral days together. If a larger quantity of oil of vitriol be added to this coagulum, it all becomes fluid, but ferments violently; and finally there will be a white matter precipitated to the bottom of the clear liquor; and if a leaf of gold be brought near this mixture it will be diſſolved even by the vapour which exhales from it. Spirit of nitre has no effect upon this mixture, either in its ſtate of a coagulum, or when reduced by more oil of vitriol into a clear liquor; but the volatile ſpirit of urine ferments violently, without the leaſt heat with it.

6. Oil of tartar *per deliquium* being added to the impregnation, the liquors would not readily mix, but remained ſeparate, the impregnation ſinking to the bottom; but on ſtirring them thoroughly together, they finally were made to unite into a white ſubſtance like butter, with a ſtrong urinous ſmell. If a ſmall quantity of corroſive ſublimate be added to this mixture, the urinous ſmell ceaſes; and if oil of vitriol be added, there is a violent fermentation occaſioned; and, in fine, a large quantity of precipitate.

7. This impregnation of *mortar* being mixed with an equal quantity of a ſolution of corroſive ſublimate, there is nothing remarkable produced, though the mixture be ever ſo much ſhaken; but if a little oil of tartar *per deliquium* be added to this, the mixture becomes turbid, and, on ſtirring all together for ſome time, it becomes white and thick like butter. If to this, more corroſive ſublimate be added in ſolution, it becomes orange-coloured; and, on more ſtirring, this becomes again white; and finally gives a white precipitate at the bottom of a tranſparent liquor.

8. If inſtead of oil of tartar an equal quantity of lime-water be added, this in the ſame manner gives an urinous ſmell, and the whole difference is, that the mixture will not become thick with this, as it will with oil of tartar.

9. The impregnation of *mortar* produced the ſame coagulum, on mixing with ſpirit of urine, that it did with oil of tartar *per deliquium*; but it made no coagulation with ſpirit of ſal armoniac with lime; the occaſion of this difference is, that the ſpirit of urine contains a great deal of volatile ſalt, and the other but little. It is a common error to ſuppoſe that the ſpirit of ſal armoniac, which is moſt pungent, contains the greateſt quantity of ſalt; but this is not the caſe, for the ſpirit made with lime is much more pungent than that with ſalt of tartar, though the laſt is well known to contain a much larger portion of ſaline particles.

10. If a piece of paper or linen be wetted in this impregnation, and afterwards dried, it takes fire very violently, and ſparkles with the ſame violence as if it was impregnated with ſalt-petre.

From theſe experiments it is abundantly proved, that the impregnation of *mortar* contains a large quantity of a ſaline and nitrous armoniac ſalt; for a diſſolution of ſal armoniac and ſpirit of nitre mixed together are found to produce all the changes in the different bodies before named, that the impregnation does. On the whole, though it has been ſuppoſed by Mr. Tournefort, and others, that *mortar* contained ſalt-petre, ſea ſalt, and a fixed alkali; yet there does not appear any proof of its containing any of theſe ſalts; no fixed alkali can ever be ſeparated from the impregnation of it; and though the linen or paper wetted in the impregnation of it ſparkled when on fire, yet it is not nitre, but merely a nitrous ſal armoniac, which occaſions that phenomenon. The ſame effect is produced, if the linen or paper be wetted with a mixture of ſpirit of urine and ſpirit of nitre. And the ſeveral experiments before recited prove, that there is in *mortar* a ſpirit of nitre and a ſpirit of ſea ſalt, which, with the volatile urinous ſalts, form a nitrous or a ſaline armoniac. Mem. Acad. Scienc. Par. 1734.

MORTAR, in *Chemiſtry*, is an inſtrument, very uſeful for the diviſion of bodies, partly by percuſſion, and partly by grinding. They have the form of an inverted bell; and are made of all ſizes and materials, as marble, copper, glaſs, iron, grit-ſtone, and agate. The matter intended to be pounded is to be put into them, and there ſtruck and bruiſed by a long inſtrument called a *peſtle*. This, when large and heavy, ought to be ſuſpended by a cord or chain, fixed to a moveable pole, placed horizontally above the *mortar*, which conſiderably relieves the operator, becauſe its elaſticity aſſiſts the raiſing of the peſtle.

MORTAR-PIECE, in the *Military Art*, a ſhort piece of ordnance, thick and wide, proper for throwing bombs, carcaſes, ſhells, ſtones, bags filled with grape-ſhot, &c. The uſe of *mortars* is thought to be older than that of CANNON: for they were employed in the wars of Italy, to throw balls of red-hot iron and ſtones, long before the invention of ſhells. It is generally believed that the Germans were the firſt inventors. See BOMB.

The method of throwing red-hot balls out of *mortars* was firſt put in practice at the ſiege of Straſſund in 1675, by the elector of Brandenburg; though ſome ſay, in 1633, at the ſiege of Bremen.

With us, *mortars*, which are made either of braſs or iron, are chiefly diſtinguiſhed by the diameter of the bore; e. g. a 13 inch *mortar* is that the diameter of whoſe bore is 13 inches. There are ſome of 10 and 8 inch diameters; and ſome of a ſmaller ſort, as cohorns of 4.6 inches, and royals of 5.8 inches. The principal parts of a *mortar* (*Tab.* II. *Gunnery*, *fig.* 12.) are, on the outſide, the chaſe A, the reinforce B, the breech C, and the trunnions D: in the inſide, the part where the ſhell is lodged, which is the bore; and the part where the powder is lodged, called the chamber. This is uſually made cylindrical, all but the baſe, which they make hemiſpherical; though ſome of the later engineers prefer ſpherical chambers; as the ſurfaces of thoſe, being leſs, under equal capacities, make leſs reſiſtance to the gunpowder. Hiſt. Acad. Scienc. 1740.

But this propoſition ſeems doubtful. By ſome experiments, made before the Royal Society, in 1742, it appeared, that the longeſt cylindrical chambers of the ſame capacity threw the ball fartheſt; which may give ground to ſuſpect that a long cylinder might be a better figure for the chamber of a *mortar* than a ſphere of equal capacity. See GUNNERY.

The figure of the chamber is made variouſly by different nations: the Spaniards uſe chiefly the ſpherical; the French, Germans, and Dutch, the conic, cylindric, and the concave or bottled; the Portugueſe, the parabolic, invented by count de Lippe Buckeburg; and the Engliſh make them in the form of the ſruſtum of a cone. However, the concave and cylindric chambers are reckoned the beſt. See CHAMBER.

The thickneſs of the *mortar* about the chamber is to be much greater than about the chaſe; by reaſon the gunpowder makes a much greater effort about the chamber than elſewhere: the diameter of the chamber is alſo to be much leſs than that of the bore; by reaſon bombs, ſhells, &c. are much lighter than the bullets of equal diameters; and, conſequently, leſs powder ſuffices.

MORTAR, *cochorn*, a ſmall kind of *mortar*, invented by the famous engineer baron Cochorn, to throw ſmall ſhells or grenades. Theſe *mortars* are commonly fixed, to the number of a dozen, to a block of oak, at the elevation of 45°.

MORTARS, *fire-lock*, or *bombards*, are ſmall *mortars* fixed at the end of a fire-lock: they are loaded as all common fire-locks are; and the grenade, placed in the *mortar* at the end of the barrel, is diſcharged by a flint lock; and to prevent the recoil from hurting the bombardier, the bombard reſts on a kind of halberd made for that purpoſe. They were firſt invented by major-general Siebach, a German, about the year 1740.

MORTARS, *hand*, were frequently uſed before the invention of cochorns. They were fixed at the end of a ſtaff of 4½ feet long, the other end being ſhod with iron to ſtick in the ground; while the bombardier with one hand elevates it at pleaſure, he with the other hand fires.

MORTARS, *land*, are thoſe uſed in ſieges, and of late in battles, mounted on beds, made of ſolid timber, conſiſting generally of four pieces, thoſe of the royal and cochorn excepted, which are but one ſingle block; and both *mortar* and BED are tranſported on block-carriages. There is likewiſe a kind of land-*mortars*, mounted on travelling carriages, invented by count Buckeburg, which may be elevated to any degree; whereas our's are fixed to an angle of 45 degrees, and firmly laſhed with ropes. The following table ſhews the weight of land-*mortars* and ſhells; together with the quantity of powder the chambers hold when full; the weight of the ſhells, and powder for loading them.

MORTAR, *partridge*, is a common *mortar* surrounded by thirteen other little *mortars*, bored round its circumference, in the body of its metal. The central *mortar* is loaded with a fhell, and the other with grenades. The vent of the large *mortar* being fired, communicates its fire to the fmall ones; fo that both fhell and grenades go off at once. The French ufed them in the war of 1701; and more efpecially at the fiege of Lifle, in 1708, and at the defence of Bouchain, in 1702.

MORTARS, *fea*, are thofe which are fixed in the bomb-veffels, for bombarding of places by fea: and as they are generally fired at a much greater diftance than that which is required by land, they are made fomewhat longer and much heavier than the land-*mortars*.

The following table exhibits the weight of the fea-*mortars* and fhells, and alfo of their full charges.

Nature of the *mortar*.	Powder contained in the chamber, when full.	Weight of the *mortar*.	Wt. of the fhell, when fixed.	Wt. of gunpowder contained in the fhell.
	lb. oz.	C. qr. lb.	lb.	lb. oz.
10-inch MORTARS.	12 0	15 2 26	-	-
13-inch *mortar*.	20 0	81 2 1	196	7 0
10-inch *mortar*.	12 0	34 2 13	93	-

Mr. Muller very juftly obferves, that the breech of our 13-inch fea-*mortars* is loaded with an unneceffary weight of metal. The chamber thereof contains 32 pounds of powder, and, at the fame time, they are never charged with more than 12 or 15 pounds, becaufe the bomb-veffel is unable to bear the violent fhock of their full charge. Thus the action of powder is diminifhed by the vacancy left in the chamber, which is never above half filled. As a charge of 12 or 15 pounds of powder at moft is therefore fufficient, it is evidently proved, by the theory of powder, that this will produce the greateft effect when difcharged from a *mortar* with a cylindrical chamber. He alfo proves, by a variety of experiments made by captain Defaguliers and himfelf, that the conical chamber, now ufed, is conftderably inferior to the cylindrical one, with the laft charge of powder. To facilitate the ufe of the *mortar*, it is placed in a folid carriage of timber, called the BED, whofe different parts are ftrongly bolted together. By means of this it is firmly fecured in its fituation, fo that the explofion of the powder may not alter its direction. In the middle of the upper fide of this carriage are two femicircular notches, to receive the TRUNNIONS; over thefe are fixed two very ftrong bands of iron, called the CAP-*fquares*, the middle of which is bent into a femicircle, to embrace the trunnions, and keep them faft in the *mortar*-bed. The cap-fquares are confined to the timber-work by ftrong pins of iron, called the eye-bolts, into whofe upper ends are driven the keys, chained beneath them. On the fore part of the bed a piece of timber is placed tranfverfely, upon which refts the belly of the *mortar*, or that part which contains the chamber. Thefe beds are placed upon very ftrong frames of timber, which are fixed in the bomb-ketch. They are fecurely attached to the frames, by means of a ftrong bolt of iron, called the PINTLE, paffing perpendicularly through both, and afterwards through one of the beams of the veffel. Thus the pintle, which paffes through the hole in the centre, ferves as an axis to the bed; fo that the *mortar* may be turned about horizontally as occafion requires.

MORTARS, *ftone*, ferve to throw ftones into the enemy's works, when near at hand; fuch as from the town into the trenches in the covert-way, or upon the glacis; and from thefe trenches into the town. The bore is terminated by two quadrants of a circle, terminated by the reinforce and lines drawn from the ends of the cylinder, made to lodge the tompions parallel to the axis of the *mortar*. The bottom of the conic chamber is terminated by an arc of 60 degrees, and the round part of the outfide is a femicircle. The weight of a 13-inch ftone-*mortar* is 10 C. 3qr. 4 lb. and the chamber contains three pounds of powder. Muller's Artillery, part iii. p. 116, &c.

MORTAR, *to charge*, or *load in*, the proper quantity of gunpowder is put into the chamber; and, if there be any vacant fpace, they fill it up with hay; fome chufe a wooden plug to cover this they lay a turf, fome a wooden tampion, fitted to the bore of the piece; and laftly the bomb; taking care that the fufe be in the axis thereof, and the orifice be turned from the muzzle of the piece: what fpace remains, is to be filled up with hay, ftraw, turf, &c. fo as the load may not be exploded without the utmoft violence.

The quantity of gunpowder to be ufed, is found by dividing the weight of the bomb by 30; though this rule is not always to be ftrictly obferved.

When the proper quantity of powder, neceffary to charge a fea-*mortar*, is put into the chamber, it is covered with a wad, well beat down with the rammer. After this the fixed fhell is placed upon the wad, as near the middle of the *mortar* as poffible, with the fufe-hole uppermoft, and another wad preffed down clofe upon it, fo as to keep the fhell firm in its pofition. The officer then points the *mortar*, according to the propofed inclination.—When the *mortar* is thus fixed, the fufe is opened; the priming-iron is alfo thruft into the touch-hole of the *mortar*, to clear it, after which it it is primed with the fineft powder. This done, two of the matroffes, or failors, taking each one of the matches, the firft lights the fufe, and the other fires the *mortar*. The bomb, thrown out by the explofion of the powder, is carried to the place intended: and the fufe, which ought to be exhaufted at the inftant of the fhell's falling, inflames the powder contained in it, and burfts the fhell in fplinters; which, flying off circularly, occafion incredible mifchief wherefoever they reach.

If the fervice of *mortars* fhould render it neceffary to ufe pound-fhots, 200 of them, with a wooden bottom, are to be put into the 13 inch *mortar*, and a quantity of powder, not exceeding five pounds; and 100 of the above fhot with 2½ pounds of powder, for the 10-inch *mortar*, or three pounds at moft.

MORTAR, *to elevate the*, fo as its axis may make any given angle with the horizon; they apply the artillery-level, or gunners quadrant: the ufe whereof fee under the articles LEVEL and QUADRANT.

An elevation of 70 or 80 degrees is what is commonly chofen for rendering *mortars* moft ferviceable in caffing fhells into towns, forts, &c. though the greateft range be at 45 degrees.

All the Engliſh *mortars* are fixed to an angle of 45 degrees, and laſhed ſtrongly with ropes at that elevation. Although, in a ſiege, there is only one caſe, in which ſhells ſhould be thrown with an angle of 45 degrees; that is, when the battery is ſo far off that they cannot otherwiſe reach the works: for when ſhells are thrown out of the trenches into the works of a fortification, or from the town into the trenches, they ſhould have as little elevation as poſſible, in order to roll along, and not bury themſelves; whereby the damage they do, and the terror they occaſion, are much greater than if they ſink into the ground. On the contrary, when ſhells are thrown upon magazines, or any other buildings, with an intention to deſtroy them, the *mortars* ſhould be elevated as high as poſſible, that the ſhells may acquire a greater force in their fall, and conſequently do greater execution.

If all *mortar-pieces* were, as they ought to be, exactly ſimilar, and their requiſites of powder as the cubes of the diameters of their ſeveral bores; and if their ſhells, bombs, carcaſes, &c. were alſo ſimilar; then, computing like with like, their ranges on the plane of the horizon, under the ſame degree of elevation, would be equal; and conſequently one piece being well proved, i. e. the range of the grenado, bomb, carcaſe, &c. being found to any degree of elevation, the whole work of the *mortar-pieces* would become very eaſy and exact.

But ſince *mortars* are not thus ſimilar, it is required, that the range of the piece, at ſome known degree of elevation, be accurately found by meaſuring; and from hence all the other ranges may be determined.

Thus, to find the range of the piece at any other elevation required: ſay, as the ſine of double the angle under which the experiment was made, is to the ſine of double the angle propoſed, ſo is the range known to the range required.

Suppoſe, for inſtance, it be found, that the range of a piece, elevated to 30°, is 2000 yards: to find the range of the ſame piece with the ſame charge, when elevated to 45°; take the ſign of 60°, the double of 30°, and make it the firſt term of the rule of three; the ſecond term muſt be the ſign of 90°, the double of 45°; and the third the given range 2000: the fourth term will be 2310, the range of the piece at 45°. If the elevation be greater than 45°, inſtead of doubling it, take the ſine of double its complement to 90°. As ſuppoſe the elevation of a piece be 50°, take the ſign of 80°, the double of 40°. Again, if a determinate diſtance to which a ſhot is to be caſt, be given, and the angle of elevation, to produce that effect be required; the range known muſt be the firſt

first term in the rule of three, which suppose 2000 yards; the range proposed, which we suppose 1600 yards, the second term; and the sine of 60 double of the elevation for the range of 2000 yards, the third term. The fourth term will be found the sine of 43° 52', whose half 21° 56', is the angle of elevation the piece must have, to produce the desired effect. And if 21° 56', be taken from 90°, you will have 68° 4', for the other elevation of the piece, with which the same effect will likewise be produced.

Note, to avoid the trouble of finding sines of double the angles of proposed elevations, Galileo and Torricelli give us the following table, wherein the signs of the angles sought are had by inspection.

Degrees.	Degrees.	Ranges.	Degrees.	Degrees.	Ranges.
90	0	0	0	0	0
89	1	349	66	24	7431
88	2	698	65	25	7660
87	3	1045	64	26	7880
86	4	1392	63	27	8090
85	5	1736	62	28	8290
84	6	2079	61	29	8480
83	7	2419	60	30	8660
82	8	2756	59	31	8829
81	9	3090	58	32	8988
80	10	3420	57	33	9135
79	11	3746	56	34	9272
78	12	4067	55	35	9397
77	13	4384	54	36	9511
76	14	4695	53	37	9613
75	15	5000	52	38	9703
74	16	5299	51	39	9781
73	17	5592	50	40	9841
72	18	5870	49	41	9903
71	19	6157	48	42	9945
70	20	6428	47	43	9976
69	21	6691	46	44	9994
68	22	6947	45	45	10000
67	23	7193			

The use of the table is obvious. Suppose, for instance, it be known by experiment, that a *mortar* elevated 15°, charged with three pounds of powder, will throw a bomb to the distance of 350 fathom; and it be required, with the same charge, to throw a bomb 100 fathom farther: seek in the table the number answering to 15 degrees, and you will find it 5000. Then as 350 is to 450, so is 5000 to a fourth number, which is 6428. Find this number, or the nearest to it, in the table; and against it you will find 20°, or 70°; the proper angles of elevation. See RANGE.

For the weight, dimensions, &c. of the bombs, &c. to be cast out of *mortars*, and the lines of their projection, see BOMB and PROJECTILE.

MORTARIOLUM, a word applied by different writers to different things, from their resemblance to a mortar in shape. The chemists express by this name a small mould made for fashioning their copels; and anatomists call the sockets of the teeth, the *mortariola* of the jaws.

MORTERE, in *English Antiquity*, a *mortarium*, a light or taper set in churches, to burn over the graves or shrines of the dead.

MORTGAGE, in *Law*, an obligation, whereby lands or tenements of a debtor are pawned or bound over to the creditor for money, or other effects borrowed; peremptorily to be the creditor's for ever, if the money be not repaid at the day agreed on.

In this sense, *mortgage*, in the common law, amounts to much the same with HYPOTHECA, in the civil law.

The creditor holding such land, on such agreement, is in the mean time called *tenant in mortgage*. He who lays the pawn or gage, is called the *mortgager*; and he that takes it, the *mortgagee*. If a *mortgage* include excessive usury, it is prohibited by a statute 37 Hen. VIII.

The French sometimes use the word *mortgage* in the same sense in their language, where it stands in contradistinction to a simple contract, which does not carry with it the mean profits, and which they call *vif-gage, life-pledge*.

Glanville defines *mortgage, mortuum vadium*, to be that *cujus fructus vel redditus interim percepti in nulle se acquietant*. Thus, it is called *mortgage*, i. e. *dead gage*, of *mort, death*, and *gage, pledge*; because whatever profit it yields, yet it redeems not itself by yielding such profit, except the whole sum borrowed be likewise paid at the day; the *mortgager* being by covenant to receive the profits till default of payment. Others hold it called *mortgage*, because, if the money be not paid at the day, the land *mortuur, dies*, to the debtor, and is forfeited to the creditor.

Thus if a man borrows of another a specific sum (e. g. 200 *l.*) and grants him an estate in fee, on condition that if he, the mortgager, shall repay the mortgagee the said sum of 200 *l.* on a certain day mentioned in the deed, that then the mortgagee may re-enter on the estate so granted in pledge; or, as is now the more usual way, that the mortgagee shall re-convey the estate to the mortgager; in this case the land, which is so put in pledge, is, by law, in case of non-payment at the time limited, for ever dead and gone from the mortgager; and the mortgagee's estate in the lands is then no longer conditional, but absolute. But as it was formerly a doubt, whether, by taking such estate in fee, it did not become liable to the wife's dower, and other incumbrances of the mortgagee (though that doubt has been long ago over-ruled by our courts of equity), it, therefore, became usual to grant only a long term of years, by way of *mortgage*; with condition to be void on repayment of the *mortgage*-money; which course has been since continued, principally because, on the death of the mortgagee, such term becomes vested in his personal representatives, who alone are intitled in equity to receive the money lent, of whatever nature the *mortgage* may happen to be. As soon as the estate is created, the mortgagee may immediately enter on the lands; but is liable to be dispossessed, upon performance of the condition by payment of the *mortgage*-money at the day limited. And, therefore, the usual way is to agree that the mortgager shall hold the land, till the day assigned for payment; when, in case of failure, whereby the estate becomes absolute, the mortgagee may enter upon it and take possession, without any possibility, at *law*, of being afterwards evicted by the mortgager, to whom the land is now for ever dead. But here again the courts of equity interpose: and, though a *mortgage* be thus forfeited, and the estate absolutely vested in the mortgagee, at the common law, yet they will consider the real value of the tenements compared with the sum borrowed. And, if the estate be of greater value than the sum lent thereon, they will allow the mortgager at any reasonable time to recall or redeem his estate; paying to the mortgagee his principal, interest, and expences: for, otherwise, in strictness of law, an estate worth 1000 *l.* might be forfeited for non-payment of 100 *l.* or a less sum. This reasonable advantage, allowed to mortgagers, is called the *equity of* REDEMPTION. And this enables a mortgager to call on the mortgagee, who has possession of his estate, to deliver it back and account for the rents and profits received, on payment of his whole debt and interest; thereby turning the *mortuum* into a kind of *vivum vadium*. But, on the other hand, the mortgagee may either compel the sale of the estate, in order to get the whole of his money immediately, or else call upon the mortgager to redeem his estate presently, or in default thereof to be for ever FORECLOSED from redeeming the same; i. e. to lose his equity of redemption without possibility of recall. And also in some cases of fraudulent *mortgages*, specified in 4 and 5 W. & M. cap. 16, the fraudulent mortgager forfeits all equity of redemption whatsoever. It is not, however, usual for mortgagees to take possession of the mortgaged estate, unless where the security is precarious or small; or where the mortgager neglects even the payment of interest. When the mortgagee is frequently obliged to bring an ejectment, and take the land into his own hands, it is in the nature of a pledge, or the *pignus* of the Roman law: whereas, while it remains in the hands of the mortgager, it more resembles their HYPOTHECA, which was where the possession of the thing pledged remained with the debtor. But, by 7 Geo. II. cap. 20. after payment or tender by the mortgager of principal, interest, and costs, the mortgagee can maintain no ejectment; but may be compelled to re-assign his securities. Blackst. Comm. book ii. cap. 10.

The civil lawyers distinguish twenty-six different kinds of *toxic mortgages*.

MORTIER, a badge or ensign of dignity, borne by the chancellors, and great presidents, of the parliaments of Paris. That borne by the chancellor is a piece of cloth of gold, lined and turned up with ermin; that of the first president is a piece of velvet edged with a gold lace; that of the other presidents is only a piece of gold lace.

They formerly bore it on their head, but now in their hands, except in grand ceremonies, as at the entry of a king. Hence the denomination, *presidents à mortier*.

MORTIFICATION, *necrosis*, in *Medicine*, a total extinction of the natural heat of the body, or a part thereof.

Some define *mortification* a disease, wherein the natural juices of any part quite lose their proper motion; and by that means fall into a fermentative one, and corrupt and destroy the texture of the part.

The indications of cure are, to confirm the strength or to raise and maintain the vital heat a little above the natural healthy degree, to prevent the ingress of the putrid matter

matter into the veins, and to check and remove the putrefaction that is formed. The bark is the only known ſpecific; however the uſe of it is not to be indiſcriminately admitted in every caſe: in habits that are lax and feeble, no objections can occur to prohibit it; but in inflammatory habits, nitre or mineral acids ſhould accompany it if given, and great caution is neceſſary before it is preſcribed. If the inflammation is conſiderable, the mineral acids are more proper than the bark. If the pulſe is ſtrong, large, and hard, and the extremities of the body are warm, the urine red and high-coloured, the circulation is ſufficiently ſtrong, and need not be increaſed: but if the pulſe is weak, and the ſymptoms indicate a defective vital heat, cordials will be neceſſary. Mr. Pott obſerves, that a *mortification* proceeds from a circulation that is too rapid or too languid: in the firſt caſe, bleeding and diluters, and in the ſecond, cordials and invigorating medicines muſt be preſcribed. If a putrid SCURVY affects the patient, adminiſter ſuch medicines as will oppoſe it: or, if any other diſorder attends, the proper means muſt be made uſe of by which it may moſt ſpeedily be removed.

There are two ſpecies, or rather degrees, of *mortification*; the one called a GANGRENE, which is a *mortification* in its firſt or beginning ſtate; the other, a *ſphacelus*, which is a perfect or finiſhed *mortification*.

In caſes of a perfect *ſphacelus*, or *mortification*, where the parts are become abſolutely dead, and wholly without ſenſe, and ſoft, ſo as to retain the impreſſions of one's fingers ends, and are plainly fetid and corrupted, all the medicines in the world will be ineffectual to reſtore the part to its life and ſenſe again; and all that remains to be done, is the one miſerable remedy of preſerving the reſt of the body, by cutting off that part, to prevent the *mortification* from ſpreading farther. A different method is to be taken, however, in this operation, according to the degree of the ſymptoms, and the nature of the part affected.

If only ſome extremity of the foot, tarſus, metatarſus, or inſtep, or only the bare ſkin and fat are *ſphacelated*, which is ſometimes the caſe, the whole foot is not to be amputated in that caſe, but preſerving the limb entire, the ſurgeon is only to remove that part which is vitiated; and that is frequently beſt of all done by ſuppuration, or if not to be effected by that means, may be attempted by the cauſtic. When it is to be done by ſuppuration, that is to be brought on as faſt as poſſible, and when it is done, the cruſt or eſchar of the ulcer is to be ſeparated from the ſound part with proper caution.

To haſten effectually a ſuppuration in theſe caſes, nothing is ſo ſerviceable as the making numerous long and deep ſcarifications near the ſound parts; and afterwards the inciſed parts are to be well anointed with the common digeſtive ointment, and after that treated with the balſamic cataplaſms and fomentations, in common uſe on the like occaſions.

A fomentation, alſo very ſerviceable in theſe caſes, is made by mixing, in a quart of a decoction of ſcordium, or of barley-water, vinegar of rue ſix ounces, ſpirit of wine with Venice treacle four ounces, and an ounce, or two ounces of common ſalt: this is to be applied hot with compreſſes to the part, and frequently repeated, till it is ſeen that the diſorder ſpreads no farther; which is known to be the caſe, when we ſee the tumor of the vitiated parts ſubſide, and the edges of the ſound parts become tumid all round; and on the ſecond or third day after this a ſuppuration is uſually formed, and the ſound parts gradually become ſeparated from the vitiated. After this, to ſoften and promote a ſpeedy ſeparation of the eſchar, the following cataplaſm is always found highly ſerviceable. Take of ſcordium two handfuls, mallows, marſh-mallows, and henbane, of each one handful; lavender-flowers half a handful; let theſe be boiled to the conſiſtence of a cataplaſm in vinegar, or oxycrate, and when in that ſtate add to them three ounces of flour of linſeed, one ounce of linſeed-oil, and two ounces of ſal ammoniac. This is to be applied warm over the whole, and retained in a proper degree of heat as long as ſhall be found neceſſary, by means of a brick boiled in water, and applied wrapped in a linen-cloth, or ſome other like means. After theſe methods have been uſed, and the whole ſurrounding ſkin is gently tumefied with redneſs, a cruſt, or eſchar, is then formed by degrees, and the ſound fleſh begins to ſeparate from the reſt: by this we know that the diſorder has done ſpreading, and that an entire ſeparation of the vitiated parts will very ſhortly follow.

When this ſeparation ſhews itſelf beginning, it muſt be promoted as much as poſſible, by dreſſing the part with the common digeſtive, either alone, or mixed with Venice treacle, which muſt be retained on between the ſound and dead parts. To make way for this, it is ſometimes neceſſary to divide them a little by the lancet; and when that is done, and the *dreſſing* has been applied, the before deſcribed cataplaſm ſhould be again laid on warm; and in all the ſucceeding dreſſings, whatever is found looſe of the dead part muſt be carefully removed. And if it be neceſſary, from the adheſion of the vitiated parts to the ſound, to uſe the ſciſſars, or ſcalpel, to divide them, this is always to be done with very little, either of pain or of danger; it will then be proper to dreſs the part with the digeſtive, and a plaiſter of diachylon, or the like, over it, till the corrupted parts are entirely caſt off, and the ulcer appears perfectly well cleanſed, and then the cure is eaſily perfected in the common way.

This is the gentler, and more common method; ſome ſurgeons, however, from the tediouſneſs of it, have recourſe directly, in theſe caſes, to the cauſtic. They anoint either the edges only, or elſe the whole of the corrupted part, every day, with butter of antimony, or the cauſtic ſtone liquefied, till the living parts are ſurrounded by a *ſort* of eſchar, applying afterwards the cataplaſms before deſcribed, or others of the ſame kind, to prevent the diſorder from ſpreading; and to make the corrupted parts ſeparate from the ſound, the corroſive lixivium of Boerhaave is greatly in repute, and much uſed on theſe occaſions. It is made of three ounces of very ſtrong quick-lime, mixed with nine ounces of pot-aſhes, firſt ground ſeparately to powder, and afterwards mixed, adding a little water; they are then to be put into a glaſs veſſel, and ſet in a cellar to run per deliquium.

As ſoon as they are found to become fluid, the matter muſt be put into a filtre of coarſe paper, and the clear liquor that runs through muſt be kept for uſe. It is to be uſed by dipping a bruſh or feather into it, and rubbing it over the part affected once or twice a day; or fine linen rags may be wetted with it, and applied all over the part; not forgetting, however, at the ſame time, the uſe of the before ordered cataplaſm: this application is to be continued till the corrupted part begins to caſt off in cruſts or ſcales; and when this is the caſe, it muſt be dreſſed with the common digeſtive, and when perfectly cleanſed, healed with a vulnerary balſam.

Another cauſtic, highly commended by Belloſte in theſe caſes, is made by diſſolving one part of crude mercury in two parts, either of ſpirit of nitre, or of aqua fortis. This is to be rubbed over the parts as the former, and will occaſion a ſpeedy ſeparation. Several great authors, however, adviſe the uſing the knife and actual cautery in theſe caſes, dividing and burning down to the ſound parts; but the cruelty of this method, and the pain, and ſometimes danger that attend it, make the methods of cure by ſuppuratives, and mild cauſtics, much to be preferred: indeed, the ſurgeons in general are not now ſo fond of calling in the actual cautery as formerly.

Finally, when the *ſphacelus* is ſo deeply affixed in any part of the upper or lower extremity, that it has penetrated through the muſcles as far as the bone, and has either reſiſted the force of all medicines, or the proper time for the applying them has been neglected; in this caſe, to preſerve the reſt of the body, the injured part muſt be amputated. Heiſter's Surgery, p. 217.

MORTIFICATION, in *Religion*, any ſevere penance obſerved on a religious account. How ancient and how univerſal the practice of it has been, and for what reaſons obſerved, ſee FAST.

MORTIS *cauſa donatio*. See DONATION.

MORTISE, or MORTOISE, in *Carpentry*, &c. a kind of joint, wherein a hole or inciſion, of a certain depth, is made in the thickneſs of a piece of wood, which is to receive another piece, called a *tenon*.

The word is originally French, *mortoiſe*, which ſignifies the ſame; and which Borel farther derives from *mordere*, *to bite*.

MORTMAIN, in *Law*, the alienation of lands and tenements to any guild, corporation, or fraternity, ſole or aggregate, eccleſiaſtical or temporal, and their ſucceſſors; as biſhops, parſons, vicars, &c. which may not be done without the king's licence, and that of the lord of the manor; or that of the king alone, if it be immediately holden of him. Stat. 7 & 8 W. III. cap. 37. And by ſtat. 9 Geo. II. cap. 36, no manors, lands, or money to be laid out in lands, are to be given for charitable uſes, unleſs by deed executed twelve months before the death of the donor.

The word literally denotes *dead-hand*; being a compound of *mort*, *dead*, and *main*, *hand*. Accordingly Hottoman defines *mortmain* to be the poſſeſſion of thoſe who are, as it were, immortal, becauſe they never ceaſe to have heirs; ſo that the eſtate never reverts to its firſt lord; *main*, *hand*, being uſed for poſſeſſion; and *mort*, *dead*, by antiphraſis, for immortal. Others aſſign the reaſon of the name thus: that the ſervices and other profits due for ſuch lands, ſhould not, without ſuch licence, come into a dead hand *(mainmort)*, i. e. into a hand as it were dead, that is, ſo dedicated to God, or pious uſes, as to

be different from other lands, tenements, or hereditaments, and never to revert to the donor, or any temporal or common use.

Purchases in *mortmain* were usually made by ecclesiastical bodies, the members of which (being professed) were reckoned dead persons in law; and, therefore, land holden by them might with great propriety be said to be held *in mortua manu*.

In order to understand the rise and progress of the statutes of *mortmain*, it is necessary to observe, that by the common law any man might dispose of his lands to any other private man at his own discretion, especially when the feodal restraints of alienation were worn away. Yet in consequence of these it was always, and is still, necessary for corporations to have a licence of *mortmain* from the crown, to enable them to purchase lands; and such licences of *mortmain* seem to have been necessary among the Saxons, above sixty years before the Norman Conquest. But, besides this general licence from the king, as lord paramount of the kingdom, it was also requisite, whenever there was a mesne or intermediate lord between the king and the alienor, to obtain his licence also, upon the same feodal principles, for the alienation of the specific land. And if no such licence was obtained, the king or other lord might respectively enter on the lands so aliened in *mortmain* as a forfeiture.

However such were the influence and ingenuity of the clergy, that, notwithstanding this fundamental principle, the largest and most considerable donations of religious houses happened within less than two centuries after the Conquest: and they formed contrivances for evading the necessity of obtaining licences. In process of time, it was observed, that the feodal services, ordained for the defence of the kingdom, were every day visibly withdrawn; that the circulation of landed property from man to man began to stagnate; and that the lords were curtailed of the fruits of their seignories, their escheats, wardships, reliefs, and the like: and, therefore, in order to prevent this, it was ordained by the second of king Henry III's great charters, A. D. 1217, cap. 43. ed. Oxon. and afterwards by that printed in our common statute books, that all such attempts should be void, and the land forfeited to the lord of the fee. Mag. Cart. 9 Hen. III. cap. 36. This was afterwards superseded by the statute *de religiosis*, 7 Edw. I. which provided, that no person, religious or other whatsoever, shall buy or sell, or receive, under pretence of a gift, or term of years, or any other title whatsoever, nor should by any act or ingenuity appropriate to himself, any lands or tenements in *mortmain*; upon pain that the immediate lord of the fee, or, on his default for one year, the lords paramount, and, in default of all of them, the king might enter thereon as a forfeiture.

Farther, the statute of Westminster the second, 13 Edw. I. cap. 32. enacted, that, in cases now known under the name of common recoveries, a jury should try the true right of the demandants or plaintiffs to the land; and if a religious house or corporation be found to have it, they should still recover seisin; otherwise it should be forfeited to the immediate lord of the fee, or else to the next lord, and finally to the king, upon the immediate or other lord's default. And to prevent any future evasions, when the statute of *quia emptores*, 18 Edw. I. abolished all subinfeudations, and gave liberty for all men to alienate their lands to be holden of the next immediate lord, a proviso was inserted, cap. 3. that this should not extend to authorize any kind of alienation in *mortmain*. And when afterwards the method of obtaining the king's licence, by writ of *ad quod damnum*, was marked out, by 27 Edw. I. stat. 2. it was farther provided by 34 Edw. I. stat. 3. that no such licence should be effectual, without the consent of the mesne or intermediate lords. It was afterwards enacted, by 15 Ric. II. cap. 5. that lands which had been purchased to uses (another method of evasion, to which ecclesiastical ingenuity recurred) should be amortised by licence from the crown, or else be sold to private persons: and that, for the future, uses should be subject to the statutes of *mortmain*, and forfeitable like the lands themselves: and large tracts of land adjoining to churches, and consecrated by the name of churchyards, were declared to be within the compass of the statutes of *mortmain*. And civil or lay corporations, as well as ecclesiastical, are also declared to be within the mischief, and the remedy provided by these salutary laws. Moreover it was declared, by 23 Hen. VIII. cap. 10. that all grants of lands to superstitious uses, such as obits, chanteries, &c. if granted for any longer term than twenty years, should be void. However, during all this time, it was in the power of the crown, by granting a licence of *mortmain*, to remit the forfeiture, so far as related to its own rights; and to enable any spiritual or other corporation to purchase and hold any lands or tenements in perpetuity; which prerogative is declared and confirmed by 18 Edw. III. stat. 3. cap. 3. And it was farther provided, by 7 and 8 W. III. cap. 37. that the crown, for the future, at its own discretion, may grant licences to alien or take in *mortmain*, of whomsoever the tenements may be holden.

The statutes of *mortmain* were suspended for twenty years by 1 and 2 P. and M. cap. 8. and during that time any lands or tenements were allowed to be granted to any spiritual corporation, without any licence whatsoever. And, for the augmentation of poor livings, it was enacted, by 17 Car. II. cap. 3. that appropriators may annex the great tithes to the vicarages, and that all benefices under 100*l. per annum* may be augmented by the purchase of lands without licence of *mortmain* in either case; and the like provision hath been since made, in favour of the governors of queen Anne's bounty, 2 and 3 Anne, cap. 11. It hath also been held, that, notwithstanding the statute 23 Hen. VIII. a man may give lands for the maintenance of a school, an HOSPITAL, or any other charitable uses. But as it was apprehended, from recent experience, that persons on their death-beds might make large and improvident dispositions, even for these good purposes, and defeat the political ends of the statutes of *mortmain*; it is therefore enacted, by 9 Geo. II. cap. 36. that no lands or tenements, or money to be laid out thereon, shall be given for or charged with any charitable uses whatsoever, unless by deed indented, executed in the presence of two witnesses, twelve calendar months before the death of the donor, and enrolled in the court of chancery within six months after its execution, except stocks in the public funds, which may be transferred within six months previous to the donor's death, and unless such gift be made to take place immediately, and be without power of revocation; and that all other gifts shall be void. The two universities, their colleges, and the scholars upon the foundation of the colleges of Eaton, Winchester, and Westminster, are excepted out of this act. Blackst. Com. book ii. chap. 18.

MORTUARY is a gift left by a man at his death to his parish church, for a recompence of personal tithes and offerings, not duly paid in his life-time.

Mortuary is also the fee paid to an incumbent, for carrying a corpse out of his parish to be buried in another.

A *mortuary* is not properly and originally due to an incumbent from any but those of his own parish: but, by custom, in some places of the kingdom, it is paid to the parsons of other parishes, as the corpse passes through them.

They seem to have been originally, like lay HERIOTS, only a voluntary bequest to the church, and it was anciently brought to the church with the corpse, when it came to be buried; and called a CORSE *present*: but so early as the time of Henry III. it was riveted into an established custom; insomuch that the bequests of heriots and *mortuaries* were held to be necessary ingredients in every testament of chattels.

Mortuaries are taken away in Wales, Berwick, and Cheshire, by 21 Hen. VIII. cap. 6. *sect.* 6. 12 Anne, stat. 2. cap. 6. 18 Geo. II. cap. 6.

It is enacted, by 21 Hen. VIII. cap. 6. that all *mortuaries* or corse presents to parsons of any parish shall be taken in the following manner, unless where by custom less or none at all is due: viz. for every person who does not leave goods to the value of ten marks, nothing; for every person who leaves goods to the value of ten marks, and under 30*l.* 3*s.* 4*d.* if above 30*l.* and under 40*l.* 6*s.* 8*d.* if above 40*l.* of what value soever they be 10*s.* and no more. And no *mortuary* shall throughout the kingdom be paid for the death of any feme-covert; nor for any child; nor for any one of full age, that is not a housekeeper; nor for any way-faring man; but such way-faring man's *mortuary* shall be paid in the parish to which he belongs. And upon this statute stands the law of *mortuaries* to this day.

MORTUUM *caput*. See CAPUT.

MORUS, in *Botany*. See MULBERRY.

MORXI, the Indian name of a pestilential distemper, very common in Malabar, and in some other parts of the East Indies, frequently carrying off great numbers of people.

MOSAIC, MOSAIC *work*, or, as some choose to call it, MUSAIC, an assemblage of little pieces of glass, marble, shells, precious stones, woods, or the like, of various colours, cut square, and cemented on a ground of stucco, &c. imitating the natural colours and degradations of painting. In this sense *mosaic work* includes *marquetry*, or *inlaid work*, *veneering*, &c.

The critics are divided as to the origin and reason of the name: some derive it from *musicum*, a corruption of *musivum*, as that is of *musseum*, as it was called among the Romans. Scaliger derives it from the Greek μυσα, and imagines the name was given to this sort of work,

as being very fine and ingenious. Nebricenſis is of opinion it was ſo called, becauſe *ea illis picturis ornabantur muſæa.*

But, in its more proper and reſtrained ſenſe, *moſaic* only takes in works of ſtone, metals, and glaſs; thoſe of wood being diſtinguiſhed by the name of MARQUETRY, or *inlaying*.

Others diſtinguiſh otherwiſe between *moſaic* and *marquetry*. In that properly called *moſaic*, they ſay, the ſeveral ſtones are all of the ſame colour; and the changes and diminutions of colours, and ſhades, are made by applying different ſtones one on another, but all of the ſame colour. *Marquetry*, on the contrary, conſiſts of ſtones of different colours; and by theſe the ſeveral colours, ſhades, degradations, &c. are expreſſed.

Moſaic ſeems to have taken its origin from *paving*: the fine effect and uſe of pavements compoſed of pieces of marble of different colours ſo well joined together, as that, when dried, they might be poliſhed, and the whole make a very beautiful and ſolid body, which, continually trodden upon, and waſhed with water, was not at all damaged, gave the painter the hint, who ſoon carried the art to a much greater perfection; ſo as to repreſent foliages, maſques, and other groteſque pieces of various colours, on a ground of black or white marble. In fine, obſerving the good effect which this kind of work had in pavements, and finding that it reſiſted water, they proceeded to line walls therewith, and to make various figures by it, for the ornament of their temples and public buildings. But nature not producing variety of colours enough for them in marbles, to paint all kinds of objects, they bethought of counterfeiting them with glaſs and metal colours; which ſucceeded ſo well with them, that having given all manner of teints to an infinite number of little pieces of theſe two matters, to counterfeit ſtones of various colours, in order to get more colours; the workmen arranged them with ſo much art, that their *moſaic* ſeemed almoſt to diſpute with paintings; this way of repreſenting objects having this advantage, that it reſiſts the injuries of the air, as well as marble itſelf; and even grows more beautiful with time, which effaces all other kinds of painting.

But the moderns have gone yet farther; and, ſetting aſide glaſs and metals, as too mean materials, have introduced, along with the fineſt marbles, the richeſt of precious ſtones, as lapis lazuli, agat, cornelians, emeralds, turquoiſes, &c.

Of theſe three kinds of *moſaic* work, that of coloured glaſs and metals is now little in uſe, though of a ſurpriſing luſtre and durableneſs: of the other two, that of marbles alone is in common uſe; the *moſaic* in precious ſtone being ſo very dear, that few workmen who apply themſelves to it, make little elſe but petty works, as ornaments for altar-pieces, tables for rich cabinets, &c. Though out of theſe muſt be excepted that ſumptuous chapel of the dukes of Tuſcany, which will be a noble monument of the magnificence and piety of thoſe princes, as well as of the patience and addreſs of the workmen employed therein.

We ſhall, however, enter into ſome detail of the manner of working in thoſe three kinds of *moſaics*; to which we ſhall add a fourth much newer, yet equally ingenious with any of the reſt, made with a kind of gypſum or tale, found in the ſtone-quarries about Paris.

MOSAIC *work of glaſs*. This kind they begin with little pieces of glaſs, which they provide of as many different colours as poſſible. To this end, the glaſſmen's furnaces being diſpoſed, and their pots or crucibles full of the matter of which glaſs is made, or rather of glaſs already made, they put what metalline colour or dye they think fit in each crucible, always beginning with the weakeſt, and augmenting the ſtrength of the colours from crucible to crucible, till they come to the deepeſt dye, as in mixing of colours on the pallet to paint in oil. When the glaſs has had ſufficient coction, and all the colours are in their perfection, they take out the glaſs hot, as it is, and lay it on a ſmooth marble, flatting it down with another marble, and then cut it into ſlices of equal bigneſs, and about the thickneſs of an inch and half. They then with an inſtrument, which the Italians call *bocce di cane*, make ſome pieces ſquare, and others of different figures and ſizes, as occaſion requires; theſe they diſpoſe orderly in caſes, as in painting in freſco, it is uſual to range all the different teints in ſhells, according to their colour. If it be deſired to have gold, either in the ground of the painting, or in the ornaments, or the draperies, they take ſome of the pieces of glaſs, formed and cut in the manner juſt mentioned: theſe they moiſten on one ſide with gum-water, and afterwards lay them over with gold-leaf. They then put this piece, or ſeveral pieces at a time, on a fire-ſhovel, which they place in the mouth of the furnace, after having firſt covered them with another hollow piece of glaſs. Here they continue till ſuch time as they become red-hot; after which the ſhovel is drawn out, all at once; and the gold becomes ſo firmly bound to the glaſs, that it will never afterwards leave it.

Now, to apply theſe ſeveral pieces, and out of them to form a picture, they firſt make a cartoon, or deſign; this they tranſfer on the ground or plaſter, by calquing, as in painting in freſco.

As this plaſter is to be laid thick on the wall, it will continue freſh and ſoft a conſiderable time, ſo that there may be enough prepared at once to ſerve three or four days. This plaſter is compoſed of lime made of hard ſtone, with brick-duſt ground very fine, gum tragacanth, and whites of eggs: when it is thus prepared, and laid on the wall, and the deſign finiſhed of what is to be repreſented; with pliers they take out the little pieces of glaſs, ranging them one after another, and ſtill keeping ſtrictly to the light, ſhadow, and different teints and colours repreſented in the deſign; preſſing or flatting them down with a ruler, which ſerves both to ſink them within the ground, and to render the ſurface even.

Thus, in a long time, and with an infinite deal of trouble, they finiſh the work; which is ſtill the more beautiful, as the pieces of glaſs are more uniform, and ranged at more equal heights. Some of theſe are executed with ſo much juſtneſs, that they appear as ſmooth as a table of marble, and as finiſhed and maſterly as a painting in freſco; with this advantage, that they have a fine luſtre, and will hold almoſt for ever.

The fineſt works of this kind, that have deſcended to us, and thoſe from which the moderns have retrieved the art, almoſt loſt, are thoſe of the church of St. Agnes, formerly the temple of Bacchus, at Rome; beſides ſome at Piſa, Florence, and other cities of Italy. The moſt eſteemed among the works of the moderns are thoſe of Joſeph Pine, and the chevalier Lanfranc, in the church of St. Peter at Rome. There are ſome very good ones likewiſe at Venice.

MOSAIC *work of marble, and precious ſtones*.- Theſe two kinds bear ſo near a relation to each other, as to the manner of working, that, to avoid repetition, we ſhall give them both under one; obſerving, by the way, wherein the one differs from the other, either in the ſawing or ranging of the ſtones.

Moſaic of marble is uſed in large works, as in pavements of churches, baſilics, and palaces; and in the incruſtation and veneering of the walls of the ſame edifices. As to that of ſtones, eſpecially *precious ſtones*, it is only uſed in ſmall works, as before obſerved.

The ground of *moſaic* works, wholly marble, is ordinarily a maſs of marble, either white or black. On this ground the deſign is cut with a chiſſel, having been firſt calqued. When it is dug of a ſufficient depth, i. e. an inch or more, it is filled up with marble of a proper colour, firſt contoured, or faſhioned to the deſign, and reduced to the thickneſs of the cavities, with various inſtruments. To make the pieces, thus inſerted into the cavities, hold, whoſe ſeveral colours are to imitate thoſe of the deſign, they uſe a ſtucco, compoſed of lime and marble duſt; or a maſtic, which each workman prepares differently: after which, the work is half poliſhed with a ſoft kind of ſtone.

The figures thus marked out, the painter or ſculptor himſelf draws, with a pencil, the colours of the figures not determined by the ground, and in the ſame manner makes ſtrokes or hatchings, to the places where ſhadows are to be; and when he has engraved, with a chiſſel, all the ſtrokes thus drawn, he fills them up with a black maſtic, compoſed chiefly of Burgundy pitch, poured on hot; taking off, afterwards, what is ſuperfluous, with a piece of ſoft ſtone or brick, which with water and beaten cement, takes away the maſtic, poliſhes the marble, and renders the whole ſo even, that one would imagine it only conſiſted of a ſingle piece: it is this kind of *moſaic* we ſee in the pompous church of the invalids at Paris, and the fine chapel at Verſailles; and wherewith ſome entire apartments of that palace are incruſted.

For moſaic work of precious ſtones; there are required other and more delicate inſtruments than thoſe uſed in marble; as wheels, drills, tin-plates, &c. uſed by lapidaries, and carvers in ſtone. As none but the richeſt marbles and ſtones enter this work, to make them go the farther, they are ſawn into the thineſt leaves imaginable, ſcarce exceeding half a line in thickneſs: the block to be ſawed, is faſtened firmly with cords, on the bench, only raiſed a little on a piece of wood, one or two inches high. Two iron pins, which are on one ſide the block, and which ſerve to faſten it, ſerve alſo to direct the ſaw. The pieces to be ſawed are put into a vice contrived for the purpoſe: in which ſtate, with a kind of ſaw or bow made of a fine braſs wire, bent on a piece of ſpringy wood, together

with emery moiſtened with water, the leaf is gradually faſhioned, by following the ſtrokes of the deſign made on the paper and then glued to the piece.

When there are pieces enough faſhioned to form an entire flower, or ſome other part of the deſign, they are applied. The ground, that ſuſtains this *moſaic*, is uſually of ſtone. The matter, wherewith the ſtones are joined together, is maſtic, or ſtucco, laid very thin on the leaves as they are faſhioned; and the leaves in this ſtate are applied with pivers. If any contour, or ſide of a leaf, be not either rounded enough, or ſquared enough, to fit the place where it is to be uſed, when it is too large, it is brought down with a braſs file or raſp; and when too ſmall, is managed with a drill, and other lapidary inſtruments.

Manner of making MOSAIC *work of gypſum.* This is a kind of coarſe ruled or ſhining tranſparent ſtone, found in the quarries of Montmartre near Paris, among the ſtones thence dug to make the plaſter of Paris. It is different from the plaſter; but retains the name which the Romans gave the plaſter, viz. GYPSUM.

Of this ſtone, calcined in a kiln, beaten in a mortar, and paſſed through a ſieve, they make a kind of artificial marbles, imitating precious ſtones; and of theſe they compoſe a kind of *moſaic* work, which comes little ſhort either of the durableneſs or vivacity of the natural ſtones; and which has this advantage, that it admits of continued pieces, or paintings, of entire compartiments, without any joining viſible.

Some make the ground of plaſter of Paris, others of freeſtone: if the former, it is ſpread in a wooden frame, of the length and breadth of the intended work, and about an inch and half thick. This frame is ſo contrived, as that the tenons being only joined to the mortiſes by ſingle pins, they may be taken aſunder, and the frame be diſmounted when the plaſter is dry; this frame they cover on one ſide with a ſtrong linen cloth, nailed all round; and being placed horizontally, with the linen at bottom, it is filled with plaſter, paſſed through a wide ſieve: the plaſter being half-dry, the frame is ſet perpendicular, and left till it be quite dry, and then taken out, by diſmounting the frame. In this *moſaic*, the ground is the moſt important part. Now, to prepare the ſifted gypſum to be applied on this ground, they diſſolve and boil it in the beſt Engliſh glue; and, after mixing with it the colour it is to bear, the whole is worked up together into the ordinary conſiſtence of plaſter; and then taken and ſpread on the ground, five or ſix inches thick. It muſt be obſerved, that if the work be ſuch, as that mouldings are required, they are formed with gouges, and other inſtruments.

It is on this plaſter, thus coloured like marble, or precious ſtone, and which is to ſerve as a ground to a work either of lapis lazuli, agat, alabaſter, or the like, that the deſign to be repreſented is drawn; having been firſt pounced, or calqued. To hollow or impreſs the deſign, they uſe the ſame inſtruments with the ſculptors; the ground, whereon they are to work, not being much leſs hard than marble itſelf. The cavities, thus made in the ground, are filled up with the ſame gypſum boiled in glue, only differently coloured: and thus are the ſeveral colours of the original repreſented. To have the neceſſary colours and teints at hand, they temper quantities of the gypſum with the ſeveral colours, in little pots. When the deſign is thus filled, and rendered viſible, by half-poliſhing it with brick, or ſoft ſtone; they go over it again, cutting ſuch places as are either to be weaker, or more ſtrongly ſhadowed, and filling them with gypſum; which is repeated till all the colours, added one after another, repreſent the original to the life. The work being finiſhed, is ſcoured with ſoft ſtone, ſand, and water; then with pumice-ſtone; and, laſtly, poliſhed with a wooden rubber, and fine emery: then a luſtre is given it, by ſmearing it over with oil, and rubbing it a long time with the palm of the hand; which gives it a gloſs nothing inferior to that of natural marble.

If it be only required to make a variegated table, or other work of ſeveral colours, without *moſaic* figures; the proceſs is ſomewhat different. To this end, they only prepare ſeparately, in large bowls, as many different colours as nature ſhews in the marble to be imitated; and, after incorporating them with the gypſum and glue-water, they take a trowel full of each, and diſpoſe them in a trough, without any order; then, without mingling them, and only by cutting or croſſing the gypſum of each trowel once or twice with each of the reſt, they give them that beautiful confuſion, for which natural marbles are ſo much valued: of theſe they then make their tables, or lay a mould, according to the work to be done.

As to MOSAIC *work of wood*, more properly called MARQUETRY, or *inlaid work*, the ancients were well acquainted with it, and uſed it for the adorning of their beds, tables, and other moveables; employing, for this purpoſe, ivory, beſides the richeſt woods.

There are, beſide theſe, two other branches of *moſaic* work; the one called DAMASKEENING, or *damaſk work*, conſiſting in an aſſemblage of gold or ſilver threads, of which are ſometimes formed flat works, and ſometimes baſſo-relievos.

The other is called *ſhell-work*; conſiſting of ſhells, artificial congelations, petrifications, &c. uſed in grottos.

MOSCH, a name of a ſort of reſiniferous veſſels, ſaid to have been diſcovered by Baſſius, in the kidneys.

MOSCHELÆUM, a name given by authors to a compound, fragrant, and aromatic oil, in which muſk is a predominating ingredient.

MOSCHATELLINA, *hollow root*, or *tuberoſe muſkwort*, in *Botany*, the name of a little plant common under our hedges in ſpring, which conſtitutes a peculiar genus, under the title of ADOXA: the characters of which are theſe: the empalement of the flower is biſid and permanent; the flower conſiſts of one leaf, and is rotated and divided into four ſegments at the edge; from the cup of this riſes a piſtil, which is fixed in the manner of a nail to the middle of the flower; and finally becomes a ſoft ſucculent berry, which hath four cells, containing flatted ſeeds; the leaves and flowers ſmell like muſk, whence it has been called by ſome *muſk-roſeſeed*.

MOSCHELAPHUS, in *Natural Hiſtory*, a name given by ſome writers to a creature of a mixed nature, produced by the copulation of a ſtag with a cow. Wagner tells us, that theſe creatures are ſometimes ſeen in the mountainous parts of Switzerland; as are alſo the hippotauri, generated between a bull and a mare; but neither of theſe ever propagate their ſpecies. See BUSELAPHUS.

MOSCHIFERUM *animal*, or *moſchus moſchiferus* of Linnæus, *muſk*, in *Natural Hiſtory*, the name of the creature which affords us the perfume called MUSK.

This creature ſeems to be neither of the goat nor deer-kind, and it is doubtful whether or not it chews the cud; it has however no *dentes inciſores* in the upper-jaw, which ſeems a mark that it does; but it has, according to the obſervation of Ariſtotle, two exerted teeth or tuſks there, in the manner of the boar; his noſe is ſharp like that of a greyhound; his ears like a rabbit's, about three inches long, and erect; and his tail or feut, about two inches; his foot is deeply cloven; the hair on the body is about half an inch long, and very thick, and of a brown and white colour. *Tab.* III. *Quadrupeds*. N° 38. The female is leſs than the male; the noſe ſharper; wants the two tuſks, and has two ſmall teats.

The *muſk* bladder or bag is about three inches long, and two over, ſwelling out an inch and half from the belly of the male, and ſtanding as much before the groin. It has no horns, and its tuſks by their figure ſeem intended equally for feeding and fighting.

MOSCHUS, in *Zoology*, a genus of the *pecora*; the characters of which are, that it has no horns, and two long tuſks in the upper jaw. Linnæus enumerates three ſpecies, one of which is the MOSCHIFERUM *animal*.

MOSES, in *Sea Language*, is a very flat broad boat, uſed by merchant ſhips amongſt the Caribbee iſlands, to bring hogſheads of ſugar off from the ſea-beach to the ſhipping, which are anchored in the roads.

MOSQUE, or MOSK, among the *Mahometans*, is a temple ſet apart for the exerciſes of their religion.

The word comes from the Turkiſh *meſgid*, or *meſchid*, which properly ſignifies a temple built of wood, ſuch as the Turks firſt uſed. Hence the Spaniards derive their *meſchera*, and the Italians *moſchea*, and the French and Engliſh *moſque*, and *moſk*. Borel derives the word from the Greek μοσχος, *calf*, becauſe of the frequent mention of a cow in the Alcoran: but others, with the greateſt appearance of reaſon, derive it from the Arabic *maſgiad*, a place of worſhip.

There are royal *moſques* founded by the emperors, as the Solimania, and Veliſca, at Conſtantinople; and private *moſques* founded by muftees, viziers, baſſas, &c.

Moſques are built like large halls, with iſles, galleries, and domes; and are adorned on the inſide with compartiments, and pieces of *Arabeſque* work. On one ſide is always found a pool with ſeveral cocks; and on the top is placed a crelcent.

The women are not allowed to enter the *moſques*, but ſtay in the porches without.

Moſt of the *moſques* have a kind of hoſpital belonging to them, in which travellers of any religion are entertained during three days.

The Turks have converted moſt of the Chriſtian churches into *moſques*.

MOSS, MUSCUS, in *Botany*, an order of plants, belonging to the *cryptogamia* claſs, conſiſting in the Linnæan ſyſtem of

eleven

eleven genera: viz. *lycopodium*, *porella*, *sphagnum*, *phascum*, *splachnum*, *polytricum*, *muium*, *hypnum*, *fontinalis*, and *buxbaumia*. These are found growing on the barks of trees as well as on the ground. See *Tab. Mosses*.

The moſt eſteemed and odoriferous *moſs* is that of the cedar.

It is of ſome medicinal uſe; being aſtringent, and proper to ſtop hæmorrhages and dyſenteries.

The ancients took the *moſs* of trees to be the effect of a diſorder or diſcompoſure of the texture of the bark; or, at moſt, a kind of little filaments ariſing from the bark: but the moderns find, by ſeveral obſervations, that *moſſes* are all real, diſtinct plants, whoſe ſeed, being extremely ſmall, is incloſed in little capſulæ; which burſting of themſelves, the ſeed is carried off by the winds; till, falling into the inequalities of the bark of trees, it is there ſtopped, takes root, and feeds at the expence of the tree, as mouldineſs does on bread, &c.

What the botanical writers ſtrictly underſtand by the word *moſs*, is a claſs of plants appearing of an inferior rank, to the common vegetables; the leſs perfect genera of which have been ſuppoſed to be wholly deſtitute of flower or ſeed, or any thing analogous to either, and to conſiſt of ſimple, ſimilar, and uniform parts; the genera a little above theſe have ſome diverſity of parts, and carry ſomething that looks analogous to vegetation in the common way, having a reſemblance of thoſe parts which ſerve other plants for their fructification. The more perfect genera of the *moſſes* not only conſiſt of different parts, but have alſo their appropriated organs containing a pulpy matter, which finally becomes dry, and aſſumes the form of a fine and ſubtile powder, compoſed of granules, each of which is either a ſeed or a granule of farina, ſerving for the propagation of the ſpecies.

The more imperfect *moſſes* are diſtinguiſhed from the others by their appearance to the naked eye; they are either in form of a fine lanugo, or down, covering the ſurface of different bodies; or elſe they appear as ſlender filaments, or foliaceous bodies, floating about in the water; or as filaments of a tougher texture, hanging down from the branches of old trees; or as little ſhrubs, or ſingle horns, growing erect on the parched earth of mountains and heathy places; or finally, as broad and foliaceous bodies ſpreading themſelves over the dry barks of trees or rocks, without any pedicle or other ſupport.

The more perfect kinds of *moſſes* are found in the ſhape of ſmall but regular plants, divided into ſeveral branches, and clothed with leaves; theſe are of various forms and ſtructures, ſome being broad and thin, others ſlender as hairs; ſome pellucid, others opake; ſome ſmooth, others hairy. From the alæ of theſe leaves in ſome kinds, and from the ſummit of the ſtalks in others, there ariſe heads or capſules of a various figure and ſtructure, but all unicapſular; ſome of theſe are naked, and others covered with a calyptra or hood; ſome ſtand on long pedicles, and others are placed cloſe to the ſtalks. Theſe heads are uſually called *capſulæ*, which contain their ſeeds or farina, and their pedicles *ſetæ*, in the *muia*, *hypna*, *bryi*, and *polytricha*, &c.

Theſe capſulæ, in ſome are covered with a calyptra, or hood; in others they are naked. Of the firſt kind are the *ſphacnum*, *polytricum*, *muium*, *bryum*, *hypnum*, *fontinalis*, and *buxbaumia*; and of the latter ſort, the *lycopodium*, *porella*, *ſphagnum*, and *phaſcum*.

The ſubſtance with which the heads or capſules of all the *moſſes* are filled, reſembles either ſeeds, or the ſmall globules of the farinæ of flowers, which all reſemble ſeeds of particular figures in miniature. The fructifications of theſe minute plants ſeem to be either from theſe, as ſeeds falling to the earth; or according to the opinion of ſome, they ſeem to contain only farinæ in the capſules, which impregnating certain bulbs or nodules in the alæ of the leaves, cauſe them to grow and vegetate, as is ſeen in ſome of the larger plants, as in the bulbs produced in the alæ of the leaves of the dentaria, and of the lilies, and ſome others. The former opinion, of the powder in the heads or capſules being actually perfect ſeeds, is the more probable, as the bulbs in the alæ of the leaves are found only in ſome of the hypna, and others of a few other genera; whereas the propagation is as quick and certain in thoſe which have none of them, as in thoſe which have: and the want of female parts of fructification, which makes ſo many deſiderata in the Linnæan ſyſtem of botany, is eaſily made up, and the whole explained according to the uſual courſe of nature in other vegetables, by allowing the powder in the capſules to be real ſeeds, and the ſmall globules on the pointals ſurrounding the aperture of the capſule, the farina.

The opinion of the *moſſes* growing only from theſe nodules in the alæ of the leaves, or from the impregnated ends of the branches which had received the powder from the capſules, was originally founded on the obſerving that the trailing or branched hypnums annually grew out into length, from the extremities of all their branches, and annually loſt as much of the old ſtalk at the root, as they gained of the new at the ſummit; but it appears from farther obſervations, that they are real ſeeds which are contained in form of powder in the capſules; ſince the bryums, and many others, are found growing from ſmall points or ſpots, which are aſſemblages of their minute leaves, propagated on the ground, under the old ones juſt where the powder of the capſules has fallen; and though it be allowed, that the hypnums and other trailing *moſſes* do grow from the ends of the branches, yet they may alſo be produced in form of new plants, from regular and perfect ſeeds ſhed from the capſules. It is certain that the bryums are by this means propagated and ſpread into large tufts, and the other genera may alſo be ſo propagated, though they have beſide a property of increaſing by growth of the ſtalk; which ſeems no other than the property of many of the large plants to creep at the root, and ſhoot out in length greatly from the extremities of their horizontal branches, lying on or under the ground, as thoſe ſpreading parts may more properly be ſo called than roots, the ſhoots puſhed out from them perpendicularly into the earth being properly the roots: and it is well known that theſe plants, though they propagate themſelves thus by the root, produce ſeeds alſo like the others, by which they may be equally propagated: and this analogy is to be carried yet farther; for as thoſe plants which creep by the roots produce fewer ſeeds than thoſe which are propagated only by ſeeds; ſo the hypnums, which are the genus of *moſſes* in which this growth by the ſtalks is principally obſerved, are very thinly beſet with capſules of ſeed, and many of them produce but very few in a ſeaſon; whereas the brya, and other *moſſes*, which have not this advantage of growing from the ends of the ſtalks, are found every year profuſely covered with capſules from every tuft; nay, there is ſcarce any branch which does not produce its capſule. Now if theſe capſules contained only a farina capable of impregnating the nodules, or the ends of the branches, it is obvious there would be as much of it required for the hypna as for any other kinds of *moſſes*; but if they are real and perfect ſeeds, it is no wonder that nature has given them profuſely to ſuch kinds as are to be propagated only by ſeeds, and more ſparingly to thoſe which are propagated alſo by the increaſe of the branches.

To this it may finally be added, that the ferns and other epiphylloſpermous plants approach moſt of all others to the nature of the *moſſes*; and though it has been ſuſpected by many, that the fine powder at the back of their leaves was not ſeeds, but only a farina; yet it is now well known that it is true and perfect ſeed, ſince, under many ſpecies of them, there are conſtantly found new and ſelf-ſown plants ariſing in their firſt rudiments of leaves and figure, which have plainly grown from the duſt or powder fallen from the old plants; and as this is now found to be the caſe in regard to the ferns, probably it will alſo appear the ſame in regard to *moſſes*, when they have been yet farther examined than at preſent. But whether theſe grains of powder have the lobes and radicles by which the ſeeds of larger plants propagate themſelves, or whether they grow into plants like the parent ones, in the manner of the lichens, by mere expanſion, is a thing that requires farther obſervation to determine.

Some of the *moſſes*, it is evident, approach to the nature of the plants, which have their male and female parts in the ſame flower, and others to thoſe which have them in different ones.

The manner of ſeeding of *moſſes* in general may be in ſome degree gueſſed at by that of one genus of them, which has been traced through all its ſtages, and to which moſt of the others, though every genus has its diſtinct fructification in ſome reſpects, yet bear a very great general analogy.

The genus already obſerved, is that called by Dr. Dillenius, the HYPNUM. The ſpecies of this are very numerous and common; but that particular one which was the ſubject of theſe obſervations, is the ſhort-branched ſilky-kind, common on old walls; and called by that author in his hiſtory, *hypnum vulgare, ſericeum, ramoſum, capſulis oblongis cuſpidatis*.

The head of this *moſs* appears to the naked eye a ſmall, ſmooth, brownish-yellow, oblong body, of about a ninth or an inch long; this is covered at its upper end with a membranaceous calyptra or hood, in ſhape reſembling an extinguiſher, or a funnel inverted. When this calyptra is taken off, and the head viewed with a microſcope, the ſurface of it is ſeen to be ruled with longitudinal ſtriæ. The baſis of the head is of a deep orange colour, and more opake than the reſt; and the top is bounded by an orange-coloured ring ſwelling out ſomething beyond the

furface of the contiguous parts of the head. Good glaſſes ſhew that in this head there are not wanting the parts eſſential to the fructification of what are uſually called the more perfect plants. This ring is truly a monophyllous undulated calyx, within which ariſe fifteen pyramidal imbricated ſtamina; theſe are of a pale greeniſh colour, and are loaded with a whitiſh oval farina. The ſtamina all bend toward each other from their baſes, and almoſt meet in a point at the top. This is their appearance when the head is nearly ripe; and immediately under the arch formed by theſe ſtamina, is a cylindric hollow piſtillum, through which the farina makes its way, and is diſperſed among the ſeeds in the head; the fruit is a large capſule, filling every part of the membrane which ſhews itſelf on the outſide of the head, and in moſt places is contiguous to it; this capſule is filled with perfect and very beautiful ſeeds; they are round, tranſparent when unripe, but afterwards opake, and of a very beautiful green, which colour they retain even when dried. Phil. Tranſ. N° 478. ſect. 12.

When this head is firſt produced from the plant, the ſtamina are very ſlender, and ſtand erect; the head is ſcarce any thicker than the ſtalk, and the calyptra covers it all over, to ſhield the tender ſubſtance of the farina from external injuries. As the farina afterwards ſwells in the ſtamina, the ſeeds in the head increaſe alſo in bulk, and by their increaſe the head is more extended in thickneſs; and the ſtamina are by this means ſeparated farther and farther from each other at their baſes, but bend inwards toward their points, ſo as to form a kind of arched covering over the ſtigma of the piſtillum, which is ſingle; and from hence the farina falls as it ripens into the head, and impregnates the ſeeds. *M.* Ibid.

All the *moſſes*, liverworts, and the other plants of the ſame character, poſſeſs the ſame general virtues of drying and aſtringency.

The *moſſes* of Virginia, Penſylvania, and other parts of North America, are in part the ſame with our's, and in part different; about two-thirds of the number of *moſſes* of theſe countries hitherto obſerved being common to our own country alſo, the reſt peculiar to that part of the world. Thoſe of South America are almoſt all wholly diſtinct from our's. The *moſſes* of Greenland and Lapland are moſtly of the ſame kind with thoſe of our Welch mountains. And in the mountainous parts of the world between the tropics, there are many extremely beautiful fern-like *moſſes*, unknown in all other places.

It cannot but be acknowledged, that the diſtinctions of theſe little vegetables are ſo minute, and their appearance ſo various in their difference ſtates, that very probably ſucceeding obſervations will much retrench the number deſcribed by Dillenius; but as the ſame obſervers will probably add as many new and truly diſtinct ſpecies, as they find occaſion to ſtrike off from the old liſt, there is no doubt but that the number will be found at leaſt as great as it ſtands at preſent with that author.

Moss *on trees*, in *Gardening*. The growth of large quantities of *moſs* on any kind of tree is a diſtemper of very bad conſequence to its increaſe, and much damages the fruit of the trees of our orchards.

The preſent remedy is the ſcraping it off from the body and large branches, by means of a kind of wooden knife, that will not hurt the bark, or with a piece of rough hair-cloth, which does very well after a ſoaking rain. But the moſt eſſential cure is the taking away the cauſe. This is to be done by draining off all the ſuperfluous moiſture, from about the roots of the trees, and may greatly be guarded againſt in the firſt planting of the trees, by not ſetting them too deep.

If trees ſtand too thick in a cold ground, they will always be covered with *moſs*; and the beſt way to remedy the fault is to thin them. When the young branches of trees are covered with a long and ſhaggy *moſs*, it will utterly ruin them; and there is no way to prevent it, but to cut off the branches near the trunk, and even to take off the head of the tree, if neceſſary; for it will ſprout again; and if the cauſe be in the mean time removed by thinning the plantation, or draining the land, and ſtirring the ground well, the young ſhoots will continue clear after this.

If the trees are covered with *moſs*, in conſequence of the ground's being too dry, as this will happen from either extreme in the ſoil, then the proper remedy is the laying mud from the bottom of a pond or river, pretty thick about the root, opening the ground to ſome diſtance and depth to let it in; this will not only cool it, and prevent its ſtopping growth to any great quantity of *moſs*, but it will alſo prevent the other great miſchief which fruit-trees are liable to in dry grounds, which is the falling off of the fruit too early.

The *moſſes* which cover the trunks of trees, as they always are freſheſt and moſt vigorous on the ſide which points to the north, if only produced on that, ſerve to preſerve the trunk of the tree from the ſeverity of the north-winds, and direct the traveller in his way, by always plainly pointing out that part of the compaſs.

Moſſes make an article of commerce; there being ſeveral kinds uſed in medicine, in perfuming, &c. among others, the *ſea-moſs*, called *coralline*; and the *moſs* of cedar and fir, which enter the compoſition of Cyprus powders.

The *moſs* of common trees, as oak, aſh, poplar, &c. is uſed for caulking of veſſels; it is alſo uſed by bird-merchants, to prepare cages for certain kinds of birds to hatch in.

The ſoft marſh and bog *moſſes* ſerve the poor in many places for ſtuffing their beds; and in the buſineſs of tranſporting plants from other countries, nothing is of ſo great uſe as the ſtalks and leaves of theſe little vegetables: the ſucculent plants coming over in great beauty and vigour when rolled up in dry *moſs*; and the trees and ſhrubs, by having their roots covered with ſuch as is ſomewhat moiſt.

The great quality of the *moſſes*, which makes them ſo ſerviceable in this caſe, is, that they do not heat and ferment on being moiſtened, as hay and ſtraw would.

Several ſpecies of the *moſſes* and *algæ* have been applied to medicinal uſe. Thus ſeveral of the *moſſes* are great and valuable medicines, uſed as deterſives and aſtringents; that the common *cup-moſs* is one of the greateſt remedies in the convulſive coughs of children, called the chin-cough, is known to every one; and Dr. Mead has ennobled the grey ground-lichen, by publiſhing its virtues in one of the moſt terrible of all diſeaſes, the bite of a mad dog. The common green liverworts are known medicines in diſorders of the breaſt, as are alſo all the ſpecies of polytricha. The ſeeds of our lycopodiums are given with ſucceſs in nephritic caſes; and the Indians give one of their ſpecies in many diſtempers, and, as they ſay, with great benefit. The common white ground coralloides ſerves the rein-deer of Lapland for food, when all other herbage is loſt; and the conferva ſerve for food to many of the fiſh both of the ſea and rivers, and to ſeveral water-fowl. And theſe, as well as the land *moſſes*, afford ſhelter and habitation to many inſects, and their young. Many of the ſpecies of coralloides and lichenoides are found of great uſe in that profitable branch of commerce the art of dying; and doubtleſs many others have alſo the ſame qualities, though not yet diſcovered; and we may be guided in ſearches of this kind by obſerving that many of them tinge the papers between which they are dried, with very beautiful and laſting colours.

Moss, *heath*, *coralloides*, in *Botany*, the name, according to Dillenius, of a genus of the *moſſes*; the characters of which are theſe: they are compoſed of ſtalks often branched in the manner of corals, and compoſed of parts of a different figure and appearance, not ſimple and uniform as the byſſi and conſervæ. On the ſummits of the branches there grow a ſort of fleſhy tubercles, which Micheli calls the receptacles of flowers; and the little atoms which are ſeen adhering to the different parts of the ſtalks, he calls the ſeeds. Dillenius is rather for thinking them the farinæ; and the tubercles, either the capſules of ſeeds, or the young plants, ready to fall off from the parent ſtem, and ſhoot for themſelves like the bulbs of the dentaria, biſtort, and the like. However this be, theſe are parts too minute to found generical diſtinctions on, which may be better deduced from a groſſer conſideration of the ſtalk, and the figure of the tubercles. Theſe have no rim or margin, and are uſually larger in the leſs branched kinds, and ſmaller in the more ramoſe. This being a very numerous genus of *moſſes*, it is divided into ſeveral orders: 1. The fungiform. 2. The cup-like. 3. The ramoſe or corniculate ones. Dillen. Hiſt. Muſc. p. 76. See Coralloides.

Moss, *ſilk*, in *Natural Hiſtory*, a name given by count Marſigli to a ſpecies of ſea-*moſs*, or coralline, of a very remarkable fineneſs and ſoftneſs, much more reſembling ſilk than any other of the marine productions. It is wholly compoſed of a ſort of tuft of fine hairs or filaments, and is of a bluiſh green colour, and almoſt tranſparent. It grows on rocks, ſtones, ſhells, or any thing elſe that lies in its way, and is found uſually at ſmall depths; it is not ſo tough and flexible as many other of the ſea-plants, but is eaſily rubbed to powder between the fingers. When examined by the microſcope, the ſingle filaments do not appear of the ſame equable ſurface and uniform texture; but they are ſeen to be jointed and made up as it were of a great number of pieces faſtened end by end to one another, in the manner of the beads of a lady's necklace. It is of a fine bluiſh green, and perfectly tranſparent before the microſcope, and reſembles a ſtring of gems, ſuch as the aqua marina, or ſome other like ſtone.

Moss, *ſea*. Theſe marine ſubſtances are very beautiful

when viewed by the naked eye; but when examined with the microscope, they afford a very pleasing variety of structure and conformation.

The common kinds afford a great variety of colouring, the different parts of the same plant often appearing, some brown, some yellow, some red, and some grey. On drying, these colours become less elegant; but on putting the dried substance again to soak in water, they are in some degree recovered, and the variations are usually found to be owing to the joints and knots in the stalks, which interrupt the course of the general colour, and are often themselves either black, or of a dark and deep brown. See CORALLINE.

MOSS-*tree*. See LIVER-WORT.

MOSS, *upright fir*. See LYCOPODIUM.

MOSS, *wall*, *bryum*, in *Botany*, the name of a genus of *mosses*, the characters of which are these: they produce membranaceous capsules, covered with a calyptra or hood, and standing on pedicles more or less long. In all this they agree with the hypnums; but they differ from them in that this pedicle has no covering round its base, but in the place of it has a node or tubercle. These pedicles also usually arise from the tops of the branches, or from those of the last years, which were then the tallest, though now nearer the roots. To this it is to be added, that the stalks are usually erect, less branched than in the hypnums, and not creeping. The calyptræ in some species stand strait, in others obliquely on the capsules; and the opercula, when the dusty matter within the head has arrived at its maturity, fall off transversely, sometimes with a smooth, sometimes with a jagged eye.

The characters of this genus, according to Linnæus, are, that the anthera is operculated; the calyptra smooth; and the filament arises out of the tubercle. He enumerates thirty-one species.

The family of the *bryums* being very numerous, they are divided into several orders and series by Dillenius, Hist. Muscs. The first order comprehends those which have erect heads; and of these, those of the first series have rounded, bellied, and turbinated heads.

The second series of this order of *bryums* contains those which have oblong oval, and rounded heads.

The second subdivision of the narrow-leaved *bryums* contains those of the short-leaved kind.

The third division of the first order of *bryums* comprehends those with extremely narrow, or capillaceous leaves.

Of these some resemble the hypnums, and many of these have their leaves terminated by long hairs.

The second subdivision of these *bryums* contains such as are hairy, and have capillaceous leaves; but differ from the hypnums in their proper figure, and general appearance.

The third subdivision comprehends such of these *bryums* as have curled leaves, or leaves that become variously undulated as they dry.

The fourth subdivision of these *bryums* comprehends those which have rostrated calyptræ and pointed capsules, afterwards becoming of the shape of bottles, from the rim of which there grow up several oblong bodies, in form of a beard.

The fifth subdivision of these *bryums* comprehends those which have a shorter operculum, and whose capsules appear striated when fully ripe.

The sixth subdivision of these *bryums* takes in those which have either no stalks, or at the utmost only very short ones.

The second order of the *bryums* comprehends those which have capsules, hanging downward from the bending of the pedicles. The calyptræ in these species quickly fall off, and the opercula are usually obtuse.

The first series of these comprehends those which have extremely narrow leaves.

The second series of these *bryums* contains those which have leaves a little broader, and though narrow, not capillaceous.

The first division of these contains those which have equal and cylindric branches. Dillen. Hist. Muscs.

The third series of these *bryums* comprehends such as have broad leaves.

MOSS is also a name given in many parts of England to the ground called a BOG, FEN, MARSH, or MORASS in other places.

MOSS-*berries*. See WHORTLE-*berry*.

MOSS-*troopers*, a rebellious sort of people in the north of England, that lived by robbery and rapine, not unlike the tories of Ireland, the buccaneers in Jamaica, or banditti of Italy: the counties of Northumberland and Cumberland were charged with a yearly sum, and a command of men, to be appointed by the justices of peace, to apprehend and suppress them. Stat. 4 Jac. I. cap. 1. 13 and 14 Car. II. cap. 22. 30 Car. II. cap. 2. See 6 Geo. II. cap. 37.

MOSTRA, in the *Italian Music*, a little mark set at the end of each line of a tune, thus , to shew that the first note of the next line is in that place.

If this first note be accompanied with a ♯ or ♭, it is right to place those characters with a *mostra*. Also if in a thorough bass this first note have any cyphers, it would be of use to put the same cyphers with the character, at the end of the preceding half. Again, if the part change its cleff with the first note, the cleff ought to be marked with the *mostra* in the same manner. The *mostra* is of great use, especially in quick motions, as it prepares the player for what is to come. Vide Bross. Mus. Dict. in voc.

MOSYNÆCUM *æs*, in *Metallurgy*, a name given by the ancients to a white metal made of copper, in great esteem among them.

Aristotle tells us, that it was extremely bright and of a perfect fine white colour; and adds, that it was made of copper by melting it with an admixture of a peculiar kind of earth. Strabo also mentions this; and Theopompus tells us, that it was made of copper and an earth, and that it looked so like silver, that it was called *pseudargyrus*.

Virgil mentions it under the name of *aurichalcum album*, and seems to give it great praises. We are not able at present to say what it was they used in making it. We know several things that will render copper white, as arsenic, and the like; but none of these can well be supposed to be the thing. For arsenic, and all the things we use to make our factitious metal, debase the copper, and render it brittle; whereas by the accounts of Strabo, and others, their white metal seems to have been better for all uses than the copper itself. As to their telling us that it was a sort of earth which they used on this occasion, very little regard is to be paid to the terms; for they had an inaccuracy in speaking that leaves us much in the dark, in many other things beside this. They called the *calaminaris* stone, which is an ore of zinc, by the name of *Cadmian* earth, in their description of the manner of making brass.

It has seemed absurd to some to call this white metal *aurichalcum album*, because they suppose the word *aurichalcum* to signify gold-coloured copper; but this is an error. The *aurichalcum* is but a false spelling of ORICHALCUM.

MOTACILLA, in *Ornithology*. See WATER-*wag-tail*.

MOTALAZITES. See MOATALAZITES.

MOTE, MOTA, frequently occurs, in our ancient customs, for a meeting, court, or plea.

Of *motes*, by the Saxons also called *gemotes*, considered in the sense of assemblies, or courts, there were divers kinds; as *wittenagemote*, *folcegemote*, *shiregemote*, *hundredgemote*, *burgemote*, *wardegemote*, *halimote*, *sheawegemote*, &c. See each under its proper article, WITTENAGEMOTE, FOLKEGEMOTE, &c.

MOTE, *mota*, was also used for a fortress, or castle; as *mota de Windsor*, &c.

MOTE also denoted a standing water to keep fish in; and sometimes a large ditch encompassing a castle, or dwelling-house.

MOTECTICO *stylo*. See STYLE.

MOTETTO, in the *Italian Music*, a kind of church-music, composed with much art and ingenuity from one to eight parts, with or without instruments, usually accompanied with a thorough bass. When the composer gives a loose to his fancy, without confining himself to any rules, subjects or passions, it is called FANTASIA or RICERCATA. The word is sometimes used for pieces made to hymns to saints, &c. and whole psalms are often thus called; and was probably derived from *motus*, *motion*, because the church songs were designed to move the hearts of the hearers; or because this kind of composition was originally of a very gay and lively nature. Brossard and Du-Cange.

MOTH, in *Zoology*. See PAPILIO and PHALÆNA.

MOTH, *field*, *tinea campestris*, in *Natural History*, the name given by Mr. de Reaumur to a species of insect, which in all respects resembles the *moth* so destructive of cloaths, except in its food; as that feeds upon woollen, and makes its nest or covering of that substance; this eats the leaves of trees, and in the same manner makes itself a covering from the fibres and integuments of them.

Their changes are the same with those of the common *moth*, and performed in the same manner; they only seem to differ in having a more moist food.

Mr. Reaumur first observed these on the leaves of the ash. This creature for a great part of its life wants no covering, but like the cockroaches making its way through the upper integument of the leaf, it feeds on the parenchyma and juices at length when it has eat away all the substance

of the leaf, it bites out a piece from each intire part of it, over and under its body, and fastens the edges all round with threads of its own spinning; thus making a complete case or covering, enabling it to bear the open air. This done, it marches from its place to find another leaf fit to supply it with more nourishment: thus it changes place several times during its life, and as often changes its covering, which requires but a very little time to make anew.

These are small animals of this genus; but there are others which are considerably larger, and which make their coverings of various matters and of different structure: they are usually very rough and ragged, and seem made of any matter that happens to be in the way; some species usually make them of pieces of straw and particles of chaff, others of small twigs of bushes, others of the dry leaves of the oak, broom, and other plants.

All these animals might have been described as the dependants on the beetle and fly kinds; but as they have this remarkable quality of feeding in the same manner, and making themselves cases of different materials in the manner of the *vines*, or sloaths *moth*, while in the worm-state, and in this state they are much more obvious to the eye than the flies, beetles, &c. produced of them, many of which are so small as to escape observation; this accurate author has chosen to describe them together, and in this their imperfect state. He adds an account of another set of animals somewhat allied to them, which he therefore calls the *pseudo-vines*, or false *moth*. See PSEUDO-*vines*.

MOTH *mullein*. See MULLEIN.

MOTHER, *mater*, a female, who hath borne, and stands in the relation of parent to another.

Thus Eve is called our common *mother*; Cybele, among the ancients, was the *mother* of the gods.

MOTHER, *town*, signifies the same with what we otherwise call *mater ecclesiæ*.

We meet with empresses on medals and inscriptions, with the title of *mother* of the camp; *mother* of the senate, *mother* of the country: *mater senatus, mater castrorum, mater patriæ*, &c.

MOTHER *of God*, is an attribute commonly given to the blessed Virgin. It had its origin from the Greeks, who first called her Θεοτοκος; in imitation of whom, some Latins began to call her *Deipara, Dei genitrix*. The council of Ephesus first gave a sanction to the appellation; but the fifth of Constantinople decreed, that the Virgin should always be thus called. This gave rise to terrible disputes: Anastasius, a presbyter of Nestorius, patriarch of Constantinople, first asserted, in a sermon, that the Virgin was by no means to be called Θεοτοκος; upon which words, a great tumult arising, Nestorius took his presbyter's part, and taught the same doctrine.

MOTHER-*tongue* is properly an original language, from which others are formed.

Of *mother-tongues*, Scaliger reckons ten in Europe; viz. the *Greek, Latin, Teutonic* or *German, Sclavonic, Epirotic, Scythian* or *European Tartar, Hungarian, Cantabrian, Irish*, and *British*.

MOTHER-*churches* are those which have founded or erected others. See PARISH.

In hereditary matters they say, it is not lawful for a man to enjoy, at the same time, both the *mother* and the daughter: meaning, that the canon-law does not allow an abbey and the benefices depending thereon, to be held by the same person.

MOTHER, *fits of the*. See HYSTERIC *affection*.

MOTHER, *water*. See WATER.

MOTHER *of vinegar*. See NITRE.

MOTHER *of thyme*. See THYME.

MOTHER *wort, cardiaca*, in *Botany*. Its characters are these: it hath a cylindrical five-cornered empalement of one leaf, which is permanent, and divided into five parts at the top; the flower is of the lip kind, of one leaf, with a narrow tube spreading at the brim; it has four stamina fastened to the upper lip, two of which are longer than the other; it has four germina, which afterwards become four naked oblong seeds, inclosed in the empalement. There are three species; the common sort used in medicine, growing naturally on the sides of banks in many parts of England, and flowering in July.

Linnæus has changed the title of this genus to *leonurus*. See LION'S *tail*.

It is only used in the shops as an ingredient in some of the compound waters, intended against hysteric complaints; and the country people frequently make an infusion of it in the manner of tea, for the same purpose. It is also said to be good in flatulencies, and colics, to give great relief in epileptic cases, and to destroy worms. It promotes urine, and the menses; but its power this way is greatly inferior to that of PENNY-*royal*.

The name *cardiaca*, improperly given to this plant, has led many into an opinion of its being a cordial; but experience does not shew any such thing.

MOTHER *of vinegar*. See VITRIOL.

MOTHER *Carey's chickens*, a name given by the English sailors, to birds which they suppose to be the fore-runners of a storm.

MOTION, primarily so called, or *local* MOTION, is a continued and successive change of place; or that state of a body, whereby it corresponds successively to several different places; or is present successively in different parts of space.

In this sense, the doctrine and laws of *motion* make the subject of mechanics, or statics.

The ancient philosophers considered *motion* in a more general and extensive manner: they defined it, a passage out of one state into another; and thus made six kinds of *motion*, viz. *creation, generation, corruption, augmentation, diminution*, and *lation*, or *local motion*.

Some of the later schoolmen reduce these six kinds of *motion* to four: the first is general, including any passage from one state to another; under which kind come *creation, production*, and *mutation*. The second is a passage of something already existing from one state to another; and thus *generation is a motion*. The third is a successive passage of something already existing from one term to another; and thus *alteration*, and *accretion*, are species of *motion*. The last is *lation*, or *local motion*; and thus *walking is motion*.

But the latest philosophers deny any other species beside *local motion*; and reduce all the sorts above mentioned to this one. So that we have here only to do with *lation*, or *local motion*; wherein the rest are only so many different determinations, or effects.

Physical writers, both ancient and modern, have ever been perplexed about the nature and definition of *local motion*. The Peripatetics define it by, *Actus entis in potentia, prout in potentia*, Arist. 3. Phys. cap. 2. But this notion seems too abstract and metaphysical for our days, and is of no use in explaining the properties of *motion*.

The Epicureans explain *motion* by the migration of a body, or a part of a body from one place to another; on which definition the later Epicureans refine, and call it, the migration or passage of a body from space to space; thus substituting the word *space* for that of *place*.

The Cartesians define *motion*, a passage or removal of one part of matter out of the neighbourhood of those parts immediately contiguous thereto, into the neighbourhood of others.

Which definition agrees, in effect, with that of the Epicureans: all the difference between them consisting in this; that what the one call *body*, and *place*, the other call *matter*, and *contiguous parts*.

Borelli, and other late writers after him, define *motion*, more accurately and fully, the successive passage of a body from one place to another, in a determinate time, by becoming successively contiguous to all the parts of the intermediate space.

Motion, then, is agreed to be the translation of a body from place to place; but authors differ much when they come to explain wherein this *translation* consists. And hence their divisions of *motion* become exceedingly precarious.

Aristotle, and the Peripatetics, divide all *motion* into *natural* and *violent*.

MOTION, *natural*, is that which has its principle, or moving force, within the moving body. Such is that of a stone falling towards the centre of the earth.

MOTION, *violent*, is that whose principle is without, and against which the moving body makes a resistance. Such is that of a stone thrown upwards.

The moderns generally divide *motion* into *absolute* and *relative*.

MOTION, *absolute*, is the change of absolute place, in any moving body; whose celerity, therefore, will be measured by the quantity of absolute space which the moveable body runs through.

MOTION, *relative*, is a mutation of the relative or vulgar place of the moving body; and has its celerity estimated by the quantity of relative space run through.

Others divide *motion* into *proper*, and *improper*, or *foreign*.

MOTION, *proper*, is a removal out of one proper place into another, which hereby becomes proper, as being possessed by this body alone, in exclusion of all others. Such is the *motion* of a wheel in a clock.

MOTION, *improper, extraneous, foreign*, or *common*, is the passage of a body out of one common place into another common place. Such is that of a clock when moving in a ship, &c.

The reason of all this diversity seems to arise from the not attending to the different meanings of the words, but comprizing all in one definition and division; which they should rather have distinguished into several parts.

Some, e. gr. in their definitions of *motion*, consider the

moving

moving body, not as it regards the adjacent bodies, but as it regards immoveable and infinite space. Others, again, consider the moving body, not as it regards infinite space, but as it regards other bodies vastly remote. And others, lastly, consider the moving body, not as it regards remote bodies, but that surface only to which it is contiguous.

But these various meanings being once settled, the dispute clears up. For as every thing that moves may be considered in these three several manners; there hence arise three several kinds of *motion*: wherein that which regards the parts of infinite immoveable space, without consideration of the circumambient bodies, may be called *absolutely and truly proper motion*.

That, which regards circumambient bodies vastly remote, which may themselves possibly be moved, we call *relatively common motion*.

The last, which regards the surfaces of the next contiguous bodies, inasmuch as it may want all both absolute and common *motion*, we call *relatively proper motion*.

MOTION, *absolutely and truly proper*, then, is the application of a body to different parts of infinite and immoveable space.

This alone is *proper and absolute motion*, being always generated and changed by forces impressed on the moving body itself, and by those only; and being that to which the real forces of all bodies to put others in *motion* by impulse, are owing, and to which those *motions* are proportioned. But this *motion* we cannot investigate or determine accurately; nor can we distinguish, when two bodies are impelled on each other, in which of the two (e. gr. that which appears to move the more swiftly, or the other, which appears to move more slowly, and perhaps even to be at rest) the real *motion*, and, consequently, the real force whence the impulse arose, is placed; not being able to determine whether the centre of gravity of the whole system (which is but a point in infinite space) is itself at rest, or in *motion*.

MOTION, *relatively common*, is a change of the situation of a body with respect to the other remote circumambient bodies: and this is the *motion* we speak of, when we say, that men, cities, and the earth itself move round the sun. This is also the *motion* we mean, when we estimate the quantity of *motion*, and the FORCE any body has to impel another. For instance; if a wooden sphere, filled with lead, to make it the heavier, be dropped from the hand; we use to estimate the quantity of *motion*, and the force which the sphere has to impel another, by the celerity of the sphere, and the weight of the included lead; and that truly with regard to the force itself, and the effect thereof, as it falls under our senses. But whether the real power or *motion* be in the sphere which appears to strike, or in the earth which appears to be struck; that, as has been observed above, we cannot determine.

MOTION, *relatively proper*, is the successive application of a body to the different parts of the contiguous bodies.

And this is the *motion* usually understood in physical disputes about the natures of particular things; as when we say, that heat, sound, fluidity, &c. consist in *motion*. This must be added, however, that by successive application of a body, its whole surface, taken together, must be conceived successively applied to different parts of the contiguous bodies.

From these several definitions of *motion* arise as many definitions of place: for when we speak of *motion* (or rest) *truly and absolutely proper*; then place is that part of infinite and immoveable space which the body fills. When of *motion relatively common*; then place is a part of any space or moveable dimension. When of *motion relatively proper* (which is really very improper); place is then the surface of the next adjacent bodies, or sensible spaces.

The definition of rest is pretty well agreed on; but whether rest be a mere privation of *motion*, or any thing positive, is warmly disputed. Malebranche, and others, maintain the former side of the question; Cartes, and others, the latter. These last contend, that a body at rest has no power to persevere in that rest, nor to resist any bodies that would destroy it; and that *motion* may as well be called a cessation of rest, as rest of *motion*.

The main argument urged by the former is this: Suppose a globe at rest, and suppose God cease to will its rest; what will be the consequence? It will rest still. Let it be in *motion*, and let God cease to will its *motion*; what will be the consequence? it will cease to move; that is, it will be at rest: because the power whereby a body in *motion* perseveres in that state, is the positive will of God; that whereby the quiescent body perseveres, is only his privative will.

But this is a *petitio principii*: for the force or conatus whereby bodies, whether moving or quiescent, persevere in their states, is the mere inactivity of matter; and therefore, were it possible for God not to will any thing, a body already in *motion* would move for ever; as a body at rest would rest for ever. To this inactivity of matter it is owing, that all bodies resist according to their quantities of matter; and that any body striking another with any given velocity, will move it in the same proportion which its density, or quantity of matter, has to the density, or quantity of matter, of the other.

Motion has ever been esteemed a species of quantity; and its *quantum*, or greatness, which we otherwise call its *momentum*, is estimated partly from the length of the line which the moving body describes (as if a body pass over a line of a hundred feet, the quantity of its *motion* is greater than if it passed over only ten feet), and partly from the quantity of the matter moved together, or at the same time; i. e. not from the bulk or extension of the body, but from its mass or weight; the air, and other subtile matters wherewith the pores are filled, not entering into the account: as if a body of two cubic feet run over a line of a hundred feet, the quantity of its *motion* is greater than that of a body of one cubic foot describing the same line: for whatever *motion* one whole has, that is half in one half of the other; and the *motion* of the whole is the sum of the *motion* of all its parts. See FORCE.

Hence it follows, that for two unequal bodies to have equal *motions* or momentums, the lines which they pass over must be in a reciprocal proportion of their masses or weights; i. e. if any body have three times the quantity of matter that another has, the line that it runs over must be one-third of the line run over by the other. If two bodies, then, fastened to the two extremities of a balance or lever, have their masses in reciprocal ratio of their distances from the fixed point, when these are moved, they must describe lines in a reciprocal ratio of these masses.

For instance, if the body A, (*Tab.* V. *Mechanics, fig.* 73.) have three times the mass or weight of B, and each be fastened to the extremes of the lever AB, whose fulcrum or fixed point is C, in such manner as that the distance BC is thrice the distance CA, the lever cannot incline either way, but the space which the less body moves, BE, will be thrice the space AD, which the greater moves: so that their motions will be equal. Nor is there any reason why the body A, tending downwards, should with four degrees of *motion*, should raise the body B, rather than B, tending downwards likewise, with the same four degrees of *motion*, should raise the body A: they will therefore be in æquilibrio. On which foundation depends the whole doctrine of MECHANICS.

Hence that great problem of Archimedes, with any given power, how small soever, to raise any weight given, how great soever. For by increasing the distance CB infinitely, the power of the body B will be increased infinitely.

It is allowed on all hands, that *motion* is no essential attribute of matter: and hence arises a dispute about its *production*, and to what cause its *continuation* is owing.

MOTION, *for the general laws of*, see *Laws of* NATURE.

MOTION, *quantity of, whether always the same?* The CARTESIANS maintain, that the Creator at the beginning impressed a certain quantity of *motion* on bodies; and that under such laws, as that no part of it should be lost, but the same portion of *motion* should be constantly preserved in matter: and hence they conclude, that if any moving body strike on any other body, the former loses no more of its *motion* than it communicates to the latter. This principle Sir Isaac Newton overturns in the following words: "From the various compositions of two *motions*, "it is manifest there is not always the same quantity of "*motion* in the world; for if two balls, joined together "by a slender wire, revolve with an uniform *motion* about "their common centre of gravity, and at the same time "that centre be carried uniformly in a right line drawn "in the plane of their circular *motion*, the sum of the *mo-* "*tion* of the two balls a soften as they are in a right line, "drawn from their common centre of gravity, will be great- "er than the sum of their *motions* when they are in a line "perpendicular to that other. Whence it appears, that "*motion* may be both generated and lost. But by reason "of the tenacity of fluid bodies, and the friction of "their parts, with the weakness of the elastic power in "solid bodies, nature seems to incline much rather to the "destruction, than the production of *motion*; and, in "reality, *motion* becomes continually less and less. For "bodies which are either so perfectly hard, or so soft, "as to have no elastic power, will not rebound from each "other: their impenetrability will only stop their motion. "And if two such bodies, equal to each other, be carried "with equal, but opposite *motions*, so as to meet in a "void space, by the laws of *motion* they must stop in the "very place of concourse, lose all their *motion*, and be "at rest for ever; unless they have an elastic power to "give them a new *motion*. If they have elasticity enough "to enable them to rebound with $\frac{1}{4}$, or $\frac{1}{2}$, or $\frac{3}{4}$, of the "force wherewith they meet, they will lose $\frac{3}{4}$, or $\frac{1}{2}$, or "$\frac{1}{4}$,

" I, of their *motion*. And this is confirmed by experiments: for if two equal pendulums be let fall from equal heights, so as to strike full on each other; if those pendulums be of lead, or soft clay, they will lose all, or almost all, their *motion*; and if they be of any elastic matter, they will only retain so much *motion* as they receive from their elastic power." If it be asked, how it happens, that *motion* being thus continually lost, should be continually renewed again; the same author adds, that it is renewed from some active principles, "Such as the cause of gravity, whereby the planets and comets preserve their *motion* in their orbits, and all bodies acquire a great degree of *motion* in falling; and the cause of fermentation, whereby the heart and blood of animals preserve a perpetual warmth and *motion*; the inner parts of the earth are kept continually warmed; many bodies burn and shine; and the sun himself burns and shines, and with his light warms and cherishes all things:" (as also from the cause of elasticity, by which bodies restore themselves into their former figures) "for we find but little *motion* in the world, except what plainly flows, either from these active principles, or from the command of the maker." The preservation of the same quantity of *motion* in the universe, was a principle laid down universally by Descartes; but has been found false, and holds true only in the same direction, which is thus expressed by Sir Isaac Newton: "The quantity of *motion*, which is collected by taking the sum of the *motions* directed towards the same parts, and the difference of those that are directed to contrary parts, suffers no change from the action of bodies among themselves." Newt. Princip. lib. i. See ante.

Some philosophers, after Descartes, have supposed the preservation of the same force or *vis viva*. See the articles FORCE and VIS *viva*.

But this holds only in elastic bodies, when there is a shock; and hence those philosophers have been led to maintain, that all bodies were elastic, at least in their elements, and that an inflexible body was impossible, being repugnant to the law of continuity. See CONTINUITY.

MOTION, *a to the continuation of*, or the cause why a body once in *motion* comes to persevere in it: this has been extremely controverted among physical writers; and yet it follows very evidently from one of the grand *laws of* NATURE; viz. that all bodies persevere in their present state, whether of rest or *motion*, unless disturbed by some foreign powers. *Motion* therefore, once begun, would be continued *in infinitum*, were it to meet with no interruption from external causes; as the power of gravity, the resistance of the medium, &c. So that Aristotle's principle, every thing in *motion* affects rest, is groundless. Nor has the COMMUNICATION *of motion*, or the manner how a moving body comes to affect another at rest, or how much of its motion is communicated by the first to the last, been less disputed. See the laws thereof under the word PERCUSSION.

MOTION, we have observed, is the subject of mechanics; and mechanics is the basis of all natural philosophy; which hence becomes denominated *mechanical*.

In effect, all the phenomena of nature, all the changes that happen in the system of bodies, are owing to *motion*; and are directed according to the laws thereof.

Hence, the modern philosophers have applied themselves with peculiar ardour to consider the doctrine of *motion*; to investigate the properties, laws, &c. thereof; by observation, experiment, and the use of geometry. And to this we owe the great advantages of the modern philosophy above that of the ancients; who were extremely disregardful of *motion*; notwithstanding that they seemed so sensible of its importance, that they defined nature by the first principle of *motion*, and rest of the substance wherein it is.

Among all the ancients there is nothing extant on *motion*, excepting some things in Archimedes's books, De æquoponderantibus. To Galileo a great part of the doctrine of *motion* is owing: he first discovered the general laws of *motion*, and particularly of the descent of heavy bodies, both at liberty and on inclined planes; the laws of the *motion* of projectiles; the vibrations of pendulums, and stretched chords, with the theory of resistances, &c. which were things the ancients had little notion of.

His disciple, Torricelli, polished and improved the discoveries of his master; and added to them divers experiments concerning the force of percussion, and the equilibrium of fluids. M. Huygens improved very considerably on the doctrine of the pendulum; and both he and Borelli on the force of percussion. Lastly, Newton, Leibnitz, Varignon, Mariotte, &c. have brought the doctrine of *motion* still much nearer to perfection.

The general laws of *motion* were first brought into a system, and analytically demonstrated together, by Dr. Wallis, Sir Christopher Wren, and M. Huygens, all much about the same time; the first in bodies not elastic, and the two last in elastic bodies. Lastly, the whole doctrine of *motion*, including all the discoveries both of the ancients and moderns on that head, was given by Dr. Wallis in his Mechanics, five de Motu, published in 1670.

MOTION may be considered either as *equable*, and *uniform*; or as *accelerated*, and *retarded*. *Equable motion*, again, may be considered either as *simple*, or as *compound*; and *compound motion* either as *rectilineal*, or as *curvilineal*.

And all these, again, may be considered either with regard to themselves, or with regard to the manner of their production, and communication, by percussion, &c.

MOTION, *equable*, is that wherein the moving body proceeds with the same uninterrumpting velocity.

The laws of *equable motion* are as follow; the reader being only to observe, by the way, that *mass*, or quantity of matter, is expressed by M; *momentum*, or the quantity of *motion* or impetus, by I; *time*, or the duration of *motion*, by T; *velocity*, or its swiftness, by V; and *space*, or the line it describes, by S.

Thus, if the space be $=s$, and the time $=t$; the velocity will be expressed by $\frac{s}{t}$. And if the velocity $=v$, and the mass $=m$; the momentum will likewise be $=vm$.

MOTION, *laws of uniform or equable*. 1. The velocities V and v of two bodies, moving equably, are in a ratio compounded of the direct ratio of the spaces S and s, and the reciprocal ratio of the times T and t.

For $V = \frac{S}{T}$, and $v = \frac{s}{t}$:

Therefore, $V : v :: \frac{S}{T} : \frac{s}{t}$.

And $V : v :: S : s :: T : t$; consequently $V \times T = v \times S$.

This, and the following theorems, may be illustrated in numbers, thus: suppose a body A, whose mass is as 7, that is 7 pounds, in the time of 3 seconds, passes over a space of 12 feet; and another body B, whose mass is as 5, in the time of 8 seconds, passes over a space of 16 feet: we shall then have $M=7$, $T=3$, $S=12$; $m=5$, $t=8$, $s=16$. And therefore $V=4$, $v=2$. The case then will stand thus:

$$V : v :: S : s :: T : t$$
$$4 : 2 :: 12 \times 8 : 16 \times 3 :: 4 : 2.$$

Hence, if $V=v$, then will $S=s$; T : therefore $S :: T : t$. That is, if two bodies move equably, and with the same velocities, their spaces are as the times.

The corollaries may be illustrated by numbers, in like manner as the theorems. Thus suppose $S=12$, $T=6$, $s=8$, $t=4$. Then will $V = \frac{12}{6} = 2$, and $v = \frac{8}{4} = 2$.

Consequently V being $=v$

$$S : s :: T : t$$
$$12 : 8 :: 6 : 4.$$

If $T=t$, $S : s :: V : v$: i. e. the spaces will be as the velocities.

If $V=v$, and also $t=T$, then will $S=s$; and so the bodies, moving equably, will describe equal spaces in equal times.

2. The spaces S and s, over which two bodies pass, are in a ratio compounded of the ratio of the times T and t, and of the velocities V and v.

For $V : v :: S : s :: T$

Therefore $V \times T = S \times$

And $S : s :: V T : v t$.

In numbers, $12 : 16 :: 4 \times 3 : 2 \times 8 :: 12 : 16$.

Hence, if $S=s$, $VT=vt$, so that $V : v :: t : T$. That is, if two bodies, moving equably, describe equal spaces; their velocities will be in a reciprocal ratio of their times. In numbers, if we suppose $S=12$, and $s=12$. Because $S=VT$ and $s=vt$; if $V=2$ and $v=3$, $T=6$ and $t=4$.

So that we have $V : v :: t : T$

$$2 : 3 :: 4 : 6.$$

Farther, if $t=T$, then will $V=v$; and therefore bodies which move equably, describe equal spaces in equal times, and have their velocities equal.

If $V : v :: T : t$; then $V t = v T$; and multiplying the equal quantities $V \times T$ and $v \times t$, by T, and dividing the products by $V t$ and $v T$, we shall have $: T T = S t ::$ and $S : s :: T T : t t$, or the spaces as the squares of the times.

3. The momenta, or quantities of *motion*, of two bodies moving equably, I and i, are in a ratio compounded of the velocities V and v, and the masses or quantities of matter M and m.

For $I = VM$, and $i = vm$; therefore $I : i :: VM : vm$; that is, the ratio I to i is compounded of the ratio of V to v, and of M to m.

If I=*i*, then will VM=*vm*; and therefore V : *v* :: *m* : M. That is, if the moments of two bodies, moving equably, be equal; the velocities will be in a reciprocal ratio of their masses.

And therefore if M=*m*, V=*v*; that is, if the moments and masses of two moving bodies be equal; their velocities are also equal.

4. The velocities V and *v* of two bodies, moving equably, are in a ratio compounded of the direct ratio of their momenta I and *i*, and the reciprocal one of their masses M and *m*.

Since I : *i* :: VM : *vm*

I*vm*=*i*VM

Therefore V : *v*=I*m* : *i*M.

In numbers, 4 : 2 :: 28×5 : 10×7 :: 4×1 : 2×1 :: 4 : 2. Hence, If V=*v*, then I*m*=*i*M; and therefore I : *i*=M : *m*; that is, if two bodies move equably, and with the same velocity, their momenta will be in the same ratio with their masses. If M=*m*, I=*i*; and therefore if two bodies, that have the same masses, move equably, and with equal velocity, their momenta are equal.

5. In an equable *motion*, the masses of the bodies M and *m* are in a ratio compounded of the direct ratio of their momenta, and the reciprocal ratio of their velocities V and *v*.

For, since I : *i* :: VM : *vm*

I*vm*=*i*VM

Therefore M : *m*=I*v* : *i*V.

In numbers, 7 : 5 :: 28×2 : 10×2 :: 7×1 : 5×1 :: 7 : 5. If M=*m*, then will I*v*=*i*V; and therefore I : *i*=V : *v*. That is, if two bodies, moving equably, have their masses equal, their moments will be as their velocities.

In numbers, suppose I=12, *i*=8, M=4, *m*=4; then will $V = \frac{12}{4} = 3$, and $v = \frac{8}{4} = 2$.

Therefore 1 : *i* :: V : *v*.

12 : 8 :: 3 : 2.

6. In an equable *motion*, the momenta I and *i* are in a ratio compounded of the direct ratios of the masses M and *m*, and the spaces S and *s*, and the reciprocal ratio of the times T and *t*.

For because V : *v* :: S : *s* : T

And I : *i* :: VM : *vm*

Therefore VI : *vi* : : VMS*t* : *vm*S T

And I : *i* : : MS*t* : *m*S T.

Hence, if I=*i*, then will MS*t*=*m*S T; and therefore M : *m* : : S T, S : : *m* T : M *t*, and T : *t* :: MS : *m* : *t*; that is, if two bodies, moving equably, have their momenta equal, 1. Their masses are in a ratio compounded of the direct ratio of the times, and the reciprocal one of their spaces. 2. Their spaces are in a ratio compounded of the direct ratio of the times, and the reciprocal one of their masses. 3. Their times are in a ratio compounded of their masses, and their spaces.

Farther, if M=*m*; then will S T=S *t*; and therefore S : *s*=T : *t*; that is, if two bodies, moving equably, have their momenta and their masses equal, their spaces are as their times.

Again, if T=*t*, then will S=*s*. The two moving bodies therefore, whose masses and momenta are equal, describe equal spaces in equal times.

If besides I=*i*, S=*s*, then will *m* T=M *t*; and therefore M : *m* : : T : *t*; that is, if two moving bodies, whose momenta are equal, pass over equal spaces, their masses are proportionable to their times.

Farther, if T=*t*, then will M=*m*; and therefore bodies, whose momenta are equal, and which, moving equably, describe equal spaces in equal times, have their masses equal.

If besides I=*i*, T=*t*; then will MS=*ms*; and therefore S : *s* : : *m* : M; that is, the spaces passed over in the same time, by two moving bodies, whose momenta are equal, are in a reciprocal ratio of their masses.

7. In an equable *motion*, the spaces S and *s* are in a ratio compounded of the direct ratios of the momenta I and *i*, and times T and *t*; and the reciprocal one of the masses M and *m*.

For because I : *i* : : MS *t* : *m* S T,

I*m* S T=*i*MS*t*.

Wherefore S : *s* : : IT *m* : *i* t M.

In numbers, 12 : 16 : : 3×28×5 : 8×10×7 : : 3×4×1 : 8×2×1 : : 12 : 16.

Hence, if S=*s*, IT*m*=*i*t M; and therefore I : *i* : : tM : T*m*, M : *m* : : I T : *t*, T : *t* : : M : I*m*. If two bodies therefore move equably over equal spaces, 1. Their momenta will be in a ratio compounded of the direct ratio of the masses, and the reciprocal one of the times. 2. Their masses will be in a ratio compounded of the momenta, and the times. 3. The times will be in a ratio compounded of the direct ratio of the masses, and the reciprocal one of the momenta.

If besides S=*s*, M=*m*; then will I T=*i* t; and therefore I : *i* : : : T. That is, bodies whose masses are equal, have their momenta reciprocally proportionable to the times in which they move over equal spaces.

If besides S=*s*, T=*t*; then will M=*m*; and I : *i* : : M : *m*; and therefore two bodies moving equably, and through equal spaces in equal times, have their momenta proportionable to their masses.

8. Two bodies, moving equably, have their masses M and *m*, in a ratio compounded of the direct ratios of the momenta I and *i*, and the times T and *t*, and the reciprocal one of the space *s* and S.

For because I : *i* : : : MS : *m* t T, I *m* t T=*i* MS *t*.

Wherefore M : *m* : : I T : : *t* S.

In numbers, 7 : 5 : : 3×28×16 : 8×10×12 : : 3×7×2 : 1×10×3 : : 7 : 5.

Hence, if M=*m*, then will I T=*i* t S; and therefore, I : *i* : : S T, S : : : I T : *i* t, and T : *t* : : S : I. That is, in two moving bodies, whose masses are equal; 1. The momenta are in a ratio compounded of the direct ratio of the spaces, and the reciprocal one of the times. 2. The spaces are in a ratio compounded of the momenta and the times. 3. The times are in a ratio compounded of the direct ratio of the spaces, and the reciprocal one of the momenta. If beside M=*m*, T=*t*, then will *i* S=I *s*; and therefore I : *i* : : S : *s*. That is, the momenta of two bodies, whose masses are equal, are proportional to the spaces passed over in equal times.

9. In equable *motion*, the times T and *t* are in a ratio compounded of the direct ratios of the masses M and *m*, and the spaces S and *s*, and the reciprocal one of the momenta I and *i*.

For because I : *i* : : : MS : *m* s T, I *m* s T=*i* MS *t*.

Wherefore T : *t* : : : MS : I *m* s.

Hence, if T=*t*, *i* MS=I *m* s; and therefore I : *i* :: MS : *m* s, M : *m* : : I : *i* S; and S : *s* : : I *m* : *i* M. That is, if two bodies, moving equably, describe equal spaces in equal times; 1. Their momenta will be in a ratio compounded of the masses, and the spaces. 2. Their masses will be in a ratio compounded of the direct ratio of the momenta, and the reciprocal one of the spaces. 3. The spaces will be in a ratio compounded of the direct ratio of the momenta, and the reciprocal one of the masses.

MOTION, *accelerated*, is that which continually receives fresh accessions of velocity. It is said to be *uniformly accelerated*, when in equal times its accessions of velocity are equal.

MOTION, *retarded*, is that whose velocity continually decreases. It is said to be *uniformly retarded*, when its decrease is continually proportional to the time.

MOTION, *laws of, uniformly accelerated and retarded*. It is an axiom, that a body once at rest will never move, unless some other body put it in *motion*; and when once in *motion*, it will continue for ever to move with the same velocity, and in the same direction, unless it be forced from its state by some other cause. This is evident from that fundamental axiom in philosophy, that nothing happens without a sufficient cause.

It follows, that a body, moved by one only impulse, must proceed in a right line. If then it be carried in a curve, it must be acted on by a double power; one, whereby it would proceed in a right line; another, whereby it is continually drawn out of it.

If the action and re-action of two *(mutuallie)* bodies be equal, there will no *motion* ensue; but the bodies, after collision, will remain at rest, by each other.

If a moving body be impelled in the direction of its *motion*, it will be accelerated; if by a resisting force, it will be retarded. Heavy bodies descend with an accelerated *motion*.

10. If a body move with an uniform accelerated velocity, the spaces will be in a duplicate ratio of the times.

For, let the velocity acquired in the time *t* be=*v*, then will the velocity acquired in the time 2 *t*=2 *v*, in the time 3 *t*=3 *v*, &c. and the spaces corresponding to those times, *t*, 2 *t*, 3 *t*, &c. will be as *v t*, 4 *v t*, 9 *v t*, &c. The spaces therefore are as 1. 4. 9, &c. and the times as 1. 2. 3, &c. that is, the spaces are in a duplicate ratio of the times. Hence, in a *motion* uniformly accelerated, the times are in a subduplicate ratio of the spaces.

11. The spaces passed over by a body uniformly accelerated, increase, in equal times, according to the unequal numbers 1. 3. 5. 7, &c.

For, if the times, wherein a moving body, equably accelerated, proceeds, be as 1. 2. 3. 4. 5, &c. the space passed over in one moment, will be as 1, in 2 moments as 4, in 3 as 9, in 4 as 16, in 5 as 25, &c. *(Laws* 10). If therefore you subtract the space passed over in one moment, viz. 1. from that passed over in two moments. 4. there will remain the space correfponding to the fecond moment, viz. 3. In the fame manner may be found the

ſpace paſſed over in the third moment, 9−4=5. The ſpace correſponding to the fourth moment, 16−9=7; and ſo of the reſt. The ſpace of the firſt moment therefore is as 1, that of the ſecond as 3, that of the third as 5, of the fourth as 7, of the fifth as 9, &c. Therefore the ſpaces paſſed over by a body, moving with an uniformly accelerated *motion* in equal times, increaſe according to the unequal numbers, 1, 3, 5, 7, 9, &c.

12. The ſpaces paſſed over by a body equably accelerated are in a dupliçate ratio of the velocities.

For, ſuppoſing the velocities to be V and *v*, the times T and *t*, and the ſpaces S and *s*; then will V : *v* :: T : *t*. Wherefore, ſince S : *s* :: T^2 : *t*^{2}, *(Law 10.)* S : *s* :: V^2 : *v*^{2}.

Wherefore, in a *motion* uniformly accelerated, the velocities are in a ſubdupliçate ratio of the ſpaces.

13. Heavy bodies deſcend with an uniformly accelerated *motion*, in a medium void of reſiſtance, if the ſpaces be not very great. For, ſince heavy bodies deſcend with an accelerated velocity, the power of gravity muſt continually impel them. But the power of gravity is found the ſame at all diſtances from the earth where the experiment can be made. Therefore heavy bodies muſt be driven downwards in the ſame manner in equal times. If then, in the firſt moment of time, they be impelled with the velocity *v*, they will be impelled with the ſame velocity *v* in the ſecond moment, and with the ſame in the third, fourth, &c. moments. Now the medium being ſuppoſed void of all reſiſtance *(by Hypoth.)* they will ſtill retain the velocity they acquire; and by reaſon of their equal freſh acquiſitions every minute, they will deſcend with a *motion* uniformly accelerated.

Hence, the ſpaces of deſcent are in a duplicate ratio of their times, and alſo of their velocities, and increaſe according to the uneven numbers 1, 3, 5, 7, 9, &c.

The times, and likewiſe the velocities, are in a ſubduplicate ratio of the ſpaces. See the laws of accelerated *motion*, otherwiſe illuſtrated and evinced under ACCELERATION, and *laws of the* DESCENT *of bodies*.

14. If a heavy body fall through a medium void of reſiſtance, and from a height not very great; the ſpace it paſſes over is the ſubduple of that which it would paſs over by an uniform *motion* in the ſame time, with the velocity it has acquired at the end of its fall.

For, let the right line AB *(Tab. V. Mechanics, fig. 74.)* repreſent the whole time of a heavy body's deſcent; and let this be divided into any number of equal parts; to the abſciſſes AP, AQ, AS, AB, draw the right lines PM, QI, SH, BC, which may be as the velocities acquired, in thoſe times, in the deſcent. Since then AP : AQ :: PM : QI, AP : AS :: PM : SH, &c. (Euc. VI. 2). If then the altitude of the triangle ABC be conceived to be divided into equal parts infinitely ſmall; the *motion* being uniform in a moment of time infinitely ſmall; the little area P*p*×PM may be conſidered as the ſpace paſſed over in the little moment of time P*p*. Therefore the ſpace paſſed over in the time AB, will be as the ſum of all the little areas, i. e. as the triangle ABC. But the ſpace that would be deſcribed in the ſame time AB with the uniform velocity BC, being as the rectangle ABCD, it will be to the other ſpace as 2 to 1. (Euc. I. 41).

Hence the ſpace paſſed over in half the time AB, with the velocity BC, is equal to the ſpace which the heavy body paſſes over from a ſtate of reſt in the whole time AB.

Hence, alſo, the time wherein a heavy body falls from any given altitude being given; it is eaſy to determine the ſpaces it paſſes over in each part of that time. For the method of doing this, ſee *laws of the* DESCENT *of bodies*.

15. If a body proceed with a *motion* uniformly retarded, it will paſs over half the ſpace which it would deſcribe in the ſame time by an equable *motion*.

For, ſuppoſe the given time divided into any number of equal parts; and draw the right lines BC, SH, QI, PM, thereto, which are to be as the velocities correſponding to the parts of time, BS, BQ, BP, BA; ſo as letting fall the perpendiculars HE, IF, MG, the right lines CE, CF, CG, CB, may be as the velocities loſt in the times, HE, FI, GM, AB; that is, BS, BQ, BF, BA. Since CE : CF :: EH : FI, CG : CB :: GM : BA, ABC will be a triangle (Euc. III. 1). If B*b*, therefore be a moment of time infinitely ſmall, its *motion* will be uniform; and therefore the ſpace deſcribed by the moving body will be as the little area B*b* *c*. The ſpace, therefore, deſcribed in the time AB is as the triangle ABC; viz. as the ſum of all the little areas B*b* *c*. Now the ſpace deſcribed by the body moving uniformly with the velocity BC in the time AB, is as the rectangle ABCD: therefore the former is half of this (Euc. I. 41.)

16. The ſpaces deſcribed by a *motion* uniformly retarded, in equal times, decreaſe according to the unequal numbers 7, 5, 3, 1.

For, ſuppoſe the moving body in the firſt inſtant of time to paſs over ſeven feet; I ſay, that in the ſecond, if it be equally retarded, it will paſs over 5; in the third, 3; and in the fourth, 1. For, let the equal parts of the axis of the triangle BS, SQ, QP, PA, be as the times; the ſemi-ordinates BC, SH, QI, PM, as the velocities at the beginning of any time; the traperia BSHC, SQIH, QPMI, and the triangle PAM, as the ſpaces deſcribed in thoſe times. Let then BC=4, and BS=SQ=QP=PA=1. Then will SH=3, QI=2, PM=1, *(Law 13.)* BSHC=(4+3)÷2=$\frac{7}{2}$. SQIH=(3+2)÷2=$\frac{5}{2}$. QPMI=(2+1)÷2=$\frac{3}{2}$ PAM=$\frac{1}{2}$. Conſequently the ſpaces deſcribed in equal times are as $\frac{7}{2}$, $\frac{5}{2}$, $\frac{3}{2}$, $\frac{1}{2}$, that is as 7, 5, 3, 1.

For the cauſe, &c. of the acceleration of MOTION, ſee GRAVITY, and ACCELERATION.

For the cauſe, &c. of retardation, ſee RESISTANCE, and RETARDATION.

The laws wherein MOTION *is communicated* by the colliſion and percuſſion of bodies, are very different, as the bodies are either *elaſtic* or *unelaſtic*, and as the direction of the ſtroke is either *oblique* or *direct*. See PERCUSSION.

MOTION, *ſimple*, is that produced by ſome one power.

MOTION, *compound*, is that produced by ſeveral conſpiring powers. See COMPOUND, and COMPOSITION *of motion*. Powers are ſaid to *conſpire*, when the direction of the one is not oppoſite to that of the other; as when the radius of a circle is imagined to whirl round on its centre, and a point in the ſame radius is at the ſame time ſuppoſed impelled ſtrait along it.

All *curvilinear motion* is compound; as all ſimple *motion* is rectilinear.

17. If a moving body, *(Tab. Mechanics, fig. 76.)* be acted on by a double power; the one according to the direction AB, the other according to AC; with the *motion* compounded thereof, it will deſcribe the diagonal of a parallelogram AD; whoſe ſides AB and AC it would have deſcribed in the ſame time with each of the reſpective powers apart.

For, if the body A were only acted on by the force impreſſed along AB, in the firſt inſtant of time it would be in ſome point of the right line AB, as in H, and ſo in the line HL parallel to AC; if it were only acted on by the power impreſſed in the direction AC, it would in the ſame inſtant of time be in ſome point of the line AC, as in I, and ſo in the line IL parallel to AB. But ſince the directions of the powers are not oppoſite to each other, neither of them can impede the other; and therefore the body in the ſame inſtant of time will arrive both at the lines HL and IL; and will conſequently be in the point L, where the two meet. In the ſame manner it appears, that if KM and MG be drawn parallel to AB and AC, the body in the ſecond inſtant of time will be in M, and at length in D. Q. E. D.

This important law of *motion* may be farther illuſtrated by ſuppoſing the ſpace EFGH, *(Tab. V. Mechanics, fig. 75.* to be carried uniformly forward in the direction AB, and with a velocity repreſented by AB. Let a *motion* in the direction AD, and meaſured by the right line AD, be impreſſ upon the body A in the ſpace EFGH. To thoſe who are in this ſpace, the body A will appear to move in the right line AD; but its real or abſolute *motion* will be in the diagonal AC of the parallelogram ABCD; and it will deſcribe AC in the ſame time that the ſpace by its uniform *motion*, or any point of it, is carried over a right line equal to AB, or that the body A, by its *motion* acroſs the ſpace, deſcribes AD. For it is manifeſt, that the line AD, in conſequence of the *motion* of the ſpace, is carried into the ſituation BC, and the point D to C; ſo that the body A really moves in the diagonal AC. This law may alſo be confirmed by an experiment in the following manner: let there be a wooden ſquare ABCD, *fig. 76.* ſo contrived, as to have the part BEFC made to draw out or puſh into the ſquare at pleaſure. To this part let the pulley H be joined, ſo as to turn freely on an axis, which will be at H when the piece is puſhed in, and at *h* when it is drawn out. To this part let the ends of a ſtraight wire *k* be fixed, ſo as to move along with it, under the pulley; and let the ball G be made to ſlide eaſily on the wire. A thread *m* is fixed to this ball, and goes over the pulley to I; by this thread the ball may be drawn up on the wire, parallel to the ſide AD, when the part BEFC is puſhed as far as it will go into the ſquare. But, if this part be drawn out, it will carry the ball along with it, parallel to the bottom of the ſquare DC. By this means, the ball G may either be drawn perpendicularly upward by pulling the thread *m*, or moved horizontally along by pulling out the part BEFC, in equal times, and through equal ſpaces; each power acting equably and ſeparately upon it. But if, when the ball is at G, the upper end of the thread be tied to the pin I, in the corner A of the fixed ſquare, and the moveable part BEFG be drawn out, the

ball

ball will then be acted upon by both the powers together: for it will be drawn up by the thread towards the top of the square, and at the same time carried with its wire towards its right hand BC, moving all the while in the diagonal line L; and will be found at 2 when the sliding part is drawn out as far as it was before; which then will have caused the thread to draw up the ball to the top of the inside of the square, just as high as it was before, when drawn up singly by the thread without moving the sliding part.

The converse of this law is, that the *motion* in the diagonal AC, *fig.* 75. may be resolved into the *motions* in the sides of the parallelogram AB and AD. For it is manifest that if AK, *fig.* 77. be taken equal to AD with an opposite direction, and the parallelogram AKBC be completed, the right line AB shall be the diagonal of his parallelogram; consequently, the *motion* AC compounded with the *motion* AK equal and opposite to the *motion* AD, produces the *motion* AB; that is, if from the *motion* AC, in the diagonal, you subduct the *motion* AD in one of the sides, there will remain the *motion* AB in the other side of the parallelogram ABCD.

This doctrine will receive farther illustration by resolving each of the *motions* AB and AD into two *motions*, one in the direction of the diagonal AC, and the other in the direction perpendicular to it; that is, by solving, *(Tab.* III. *Mechanics, fig.* 30.) the *motion* AB into the *motions* AM and AN, and *motion* AD into the *motions* AK and AL. For the triangles ADK and BCM being equal and similar, DK is equal to BM, or AL to AN; so that the *motions* AL and AN, being equal and opposite, destroy each other's effects; and it being an obvious and general principle, that the *motion* of a body in a right line is no way affected by any two equal powers or *motions* that act in directions perpendicular to that line, and opposite to each other, it thus appears how the body A is determined to move in the diagonal AC; and, because AK is equal to MC, it appears how the remaining *motions* AM and AK are accumulated in the direction AC, so as to produce a motion measured by AC. It appears likewise how absolute *motion* is lost in the composition of *motion*; for the parts of the *motions* AB and AD that are represented by AN and AL, being equal and opposite, destroy each other's effect, and the other parts AM and AK, only, remain in the direction of the compounded *motion* AC: while, on the contrary, in the resolution of *motion*, the quantity of absolute *motion* is increased, the sum of the *motions* AB and AD, or BC, being greater than the *motion* AC. But the sum of the *motions*, estimated in a given direction, is no way affected by the composition or resolution of *motion*, or indeed by any actions or influences of bodies upon each other, that are equal and mutual and have opposite directions.

For suppose that *(Tab.* V. *Mechanics, fig.* 78.) the *motions* are to be estimated in the direction AP; let CP, BR, DQ, be perpendicular to this direction in the points P, R and Q; then the *motions* AC, AB, AD, reduced to the direction AP, are to be estimated by AP, AR, and AQ respectively, the parts which are perpendicular to AP having no effect in that direction. Let AP meet BC in S; then because RP is to SP, as BC (or AD) to CS, that is, as AQ to SP, it follows that AQ is equal to RP, and that AR + AQ is equal to AP; that is, that the sum of the *motions* AB and AD, reduced to any given direction AP, is equal to the compounded *motion* AC reduced to the same direction. From which it is obvious, that, in general, when any number of *motions* are compounded together, or are resolved, the sum of their *motions* continues invariably the same, till some foreign influence affects them.

From the above reasoning it is plain that since about every right line, as AD, *(Tab. Mathem. fig.* 26.) a parallelogram, as ABCD, may be constructed, by making two equal triangles ACD and ABD, on one common base AD; *every rectilinear motion*, which it may be of service for the demonstration, may be considered as a compound one. But as the proportion of the sides AC and CD may be various, so also may the right line AD be described by a *motion* compounded various ways; and therefore the same rectilinear *motion* may be reduced to various compound *motions*.

Hence, if a moveable body be drawn by three several powers, according to the directions BA, AD, and AC, *(Tab.* V. *Mechanics, fig.* 79.) two of which taken together are equivalent to the third; they will be to each other as the right lines DC, DA, DB, parallel to their directions; that is, reciprocally as the sines of the angles included between the lines of their directions, and the line of direction of the third: DB being to AD as the sine of the angle BAD to the sine of the angle ABD.

19. In an equable compound *motion*, the velocity produced by the conspiring powers is, to the velocity of each of the two apart, as the diagonal AD *(fig.* 76.) of the parallelogram ABDC, in the direction of whose sides they act, to either of those sides AB or AC.

For in the same time that one of the powers will carry it over the side of the parallelogram AB, and the other over AC separately, joined together they carry it over the diagonal AD. The diagonal AD, therefore, is the space described by the conspiring powers in the same time: but in an equable *motion* the velocities in the same time are as the spaces: the velocities therefore arising from the conspiring forces are to the velocity arising from either force, as AD to AB or AC.

Hence the conspiring forces thereof being given; i. e. the ratio of the velocities being given, by the lines AB and AC given in magnitude, and the direction through those lines being given in position, or by the angle of direction; the celerity and direction of the oblique *motion* is given; because the diagonal is given both in magnitude and position.

The oblique *motion* however being given, the simple ones are not, *vice versa*, given; because the same oblique *motion* may be compounded of various simple ones.

20. In a compound *motion* produced by the same forces, the velocity is greater, if the angle of direction be less; and less, if this be greater.

For, let the greater angle of direction be BAC *(Tab.* V. *Mechanics, fig.* 80.) the less FAC; since the powers are supposed the same, AC will be common to each parallelogram AFCE and BACD, and besides AB = AF. Now it is evident, that, in the case of the greater angle, the diagonal AD is described; and, in the case of the less angle, AE: and both in the same time, because AB = AF. The velocities, therefore, are as AD to AE: wherefore since AD is less than AE, the velocity in the case of the greater angle is less than that of the less angle.

Hence, since the legs AC and CE, with the included angle, being given, the angle CEA, and thence, also, AE, is found; the velocity of the conspiring powers, and the angle of direction, in any particular case, being given, the velocity of the compound *motion*, and consequently the ratio of the velocities produced by the same powers under different angles of direction, may be determined.

For the particular laws of MOTION *arising from the collision of bodies both* elastic *and* unelastic, *and that where the directions are both* perpendicular *and* oblique, see PERCUSSION.

For curvilinear MOTION, *and the laws of* projectiles, see PROJECTILE.

For the MOTION *of pendulums, and the laws of* oscillation, see PENDULUM.

MOTION, *altitude of*. See ALTITUDE.

MOTION, *longitude of*. See LONGITUDE.

MOTION, *perpetual*, in *Mechanics*, a *motion* which is supplied and renewed from itself without the intervention of any external cause: or it is an uninterrupted communication of the same degree of *motion* from one part of matter to another, in a circle or other curve returning into itself, so that the same momentum still returns undiminished upon the first mover.

The celebrated problem of a *perpetual motion* consists in the inventing a machine, which has the principle of its *motion* within itself. M. de la Hire has demonstrated the impossibility of any such machine, and finds that it amounts to this; viz. to find a body which is both heavier and lighter at the same time; or to find a body which is heavier than itself.

To find a *perpetual motion*, or to construct an engine, &c. which shall have such a motion, is a famous problem that has employed the mathematicians of two thousand years; though none perhaps have prosecuted it with attention and correctness equal to those of the present age.

Infinite are the schemes, designs, plans, engines, wheels, &c. to which this longed-for perpetual *motion* has given birth: it were as endless as impertinent to give a detail of them all.

In effect, there seems but little in nature to countenance all this avidity and expectation: among all the laws of matter and *motion*, we know of none yet, which seem to furnish any principle or foundation for such an effect.

Action and re-action are allowed to be ever equal; and a body which gives any quantity of *motion* to another, always loses just so much of its own; but under the present state of things, the resistance of the air, the friction of the parts of machines, &c. do necessarily retard every *motion*.

To keep the *motion* on foot, therefore, either, first, there must be a supply from some foreign cause; which in a perpetual *motion* is excluded.

Or, secondly, all resistance from the friction of the parts of matter must be removed; which necessarily implies a change in the nature of things.

For, by the second *law of* NATURE, the changes made

in the *motions* of bodies, are always proportional to the impreſſed moving force, and are produced in the ſame direction with it; no *motion* then can be communicated to any engine, greater than that of the firſt force impreſſed.

But, on our earth, all *motion* is performed in a reſiſting medium, and muſt therefore of neceſſity be retarded; conſequently a conſiderable quantity of its *motion* will be ſpent on the medium.

Nor is there any engine or machine wherein all friction can be avoided; there being in nature no ſuch thing as exact ſmoothneſs, or perfect congruity; the manner of the cohesion of the parts of bodies, the ſmall proportion the ſolid matter bears to the vacuities between them, and the nature of thoſe conſtituent particles not admitting it. This friction, therefore, will alſo in time ſenſibly diminiſh the impreſſed, or communicated force; ſo that a perpetual *motion* can never follow, unleſs the communicated force be ſo much greater than the generating force, as to recompence the diminution made therein by all theſe cauſes; but *ut dat quod non habet*, and the generating force cannot communicate a greater degree of *motion* than it hath itſelf.

Or, thirdly and laſtly, there muſt be ſome method of gaining a force equivalent to what is loſt, by the artful diſpoſition and combination of mechanic powers; to which laſt point, then, all endeavours are to be directed; but how, or by what means ſuch force ſhould be gained, is ſtill a myſtery!

The multiplication of powers or forces, it is certain, avails nought; for what is gained in power is ſtill loſt in time, ſo that the quantity of *motion* ſtill remains the ſame.

This is an inviolable law of nature; by which nothing is left to art, but the choice of the ſeveral combinations that may produce the ſame effect.

Although it is allowed, that, by the reſolution of force, there is a gain or increaſe of the abſolute quantity of force, as the two forces in the ſides of the parallelogram taken together exceed the force in the diagonal which is reſolved into them, yet you cannot proceed reſolving *motion* in infinitum by any machine whatſoever; but thoſe you have reſolved muſt be again compounded, in order to make a continual movement, and the gain obtained by the reſolution will be loſt again by the compoſition. In like manner, if you ſuppoſe two bodies to be perfectly elaſtic, and that the leſſer body ſtrikes the other at reſt, there will be an increaſe of the abſolute quantity of force, becauſe the ſtriking body will be reflected; but if you ſuppoſe them both to turn round any center, after the ſtroke, ſo as to meet again, this increaſe of force will be loſt, and their *motion* will be reduced to its firſt quantity. Such a gain, therefore, of force, as muſt be afterwards loſt in the actions of the bodies, can never produce a perpetual movement. There are various ways, beſides theſe, by which abſolute force may be gained; but ſince there is always an equal gain in oppoſite directions, and no increaſe obtained in the ſame direction; in the circle of actions neceſſary to make a perpetual movement, this gain muſt be preſently loſt, and will not ſerve for the neceſſary expence of force employed in overcoming friction, and the reſiſtance of the medium. We may obſerve, therefore, that though it could be ſhewn, that in an infinite number of bodies, or in an infinite machine, there could be a gain of force for ever, and a *motion* continued to infinity, it does not follow that a perpetual movement can be made. That which was propoſed by M. Leibnitz in Auguſt, 1690, in the Leipſick Acts, as a conſequence of the common eſtimation of the forces of bodies in *motion* is of this kind, and for this and other reaſons ought to be rejected.

The poſſibility of a perpetual *motion* has been urged from the following ſpecious argument. Let the height AB (*Tab.* V. *Miſcellaneous, fig.* 81.) be divided into four equal parts AC, CD, DE, EB: ſuppoſe the body A to acquire, by the deſcent AC, a velocity as 1; and this *motion*, by any contrivance, to be tranſmitted to an equal body B; then let the body A, by an equal deſcent CD, acquire another degree of motion as 1, to be tranſmitted likewiſe to the ſame body B, which in this manner is ſuppoſed to acquire a *motion* as 2, that is ſufficient to carry it upwards from B to A; and becauſe there yet remain the motions which A acquires by the deſcents DE and EB, that may be ſufficient to keep an engine in *motion*, while B and A aſcend and deſcend by turns, it is hence concluded, that a ſufficient gain of force may be obtained in this manner, *ſo as* to produce a perpetual movement. But it ſhould be conſidered, that two equal ſucceſſive impulſes, acting upon the ſame body, will not produce a *motion* in it double of that which would be generated by the firſt impulſe; becauſe the ſecond impulſe has neceſſarily a leſs effect upon the body, which is already in *motion*, than the firſt impulſe which acted upon it while at reſt. In like manner, if there is a third and fourth impulſe, the third will have leſs effect than the ſecond, and the fourth leſs than the third. Hence it appears, that a *motion* as 2, in the preceding caſe, cannot be produced in B, by the two ſucceſſive impulſes tranſmitted from A, each of which is as 1. Maclaurin's View, &c. book ii. c. 3. See ORTYTREUS's *wheel*.

MOTION, *animal*, is that whereby the ſituation, figure, magnitude, &c. of the parts, members, &c. of animals are changed.

Under theſe *motions* come all the animal funcſtions; as *reſpiration, circulation of the blood, excretion, walking*, &c. *Animal motions* are uſually divided into two ſpecies; viz. *ſpontaneous*, and *natural*.

MOTION, *ſpontaneous*, or *muſcular*, is that performed by means of the muſcles, at the command of the will; hence alſo called *voluntary motion*. See MUSCULAR *motion*.

MOTION, *natural*, or *involuntary*, is that effected without ſuch command of the will; by the mere mechaniſm of the parts.

Such is the *motion* of the heart and pulſe; the PERISTALTIC *motion* of the inteſtines, &c.

MOTION, *inteſtine*, denotes an agitation of the particles whereof a body conſiſts.

Some philoſophers will have every body, and every particle of a body, in continual *motion*. As for fluids, it is the definition they give of them, that their parts are in continual *motion*.

And as to ſolids, they infer the like *motion* from the effluvia continually emitted through their pores.

Hence *inteſtine motion* is repreſented to be a *motion* of the internal and ſmaller parts of matter, continually excited by ſome external, latent agent, which of itſelf is inſenſible, and only diſcovers itſelf by its effects; appointed by nature to be the great inſtrument of the changes in bodies.

MOTION, in *Aſtronomy*, is peculiarly applied to the orderly courſes of the heavenly bodies.

The *motion* of the earth, from weſt to eaſt, is now generally granted among aſtronomers: ſee it proved under the article EARTH.

MOTION, *mean*. See MEAN.

The *motions* of the celeſtial luminaries are of two kinds: *diurnal*, or *common*; and *ſecondary*, or *proper*.

MOTION, *diurnal*, or *primary*, is that wherewith all the heavenly bodies, and the whole mundane ſphere, appear to revolve every day round the earth, from eaſt to weſt. This is alſo called the *motion of the primum mobile*, and the *common motion*; to diſtinguiſh it from that rotation which is peculiar to each planet, &c.* It is about the various phænomena reſulting from this *motion*, that aſtronomy is chiefly employed. See DIURNAL.

MOTION, *ſecondary*, or *proper*, is that wherewith a ſtar, planet, or the like, advances a certain ſpace every day from weſt towards eaſt.

See the ſeveral *motions* of each luminary, with the irregularities, &c thereof, under the proper articles, EARTH, MOON, STAR, &c.

MOTION, *angular*. See ANGULAR.

Horary MOTION *of the earth*. See HORARY.

Paracentric MOTION *of impetus*. See PARACENTRIC.

MOTION *of trepidation*, &c. See TREPIDATION, and LIBRATION.

MOTION, in *Muſic*, denotes the manner of beating the meaſure, to haſten or ſlacken the time of the words, or notes. See TIME.

The *motion*, in ſongs compoſed in double time, differs from that in thoſe in triple time. It is the *motion* that diſtinguiſhes courants and ſarabands from gavots, borees, chacones, &c.

MOTION, *mots*, or *movements*, in the *Italian Muſic*, has many ſignifications; ſometimes it means only a *motion* or paſſage from one note to another, at whatſoever diſtance, as a ſecond, third, or any other interval; and in the ſame whether the intermediate degrees (if there are any) be ſounded, or only the extremes of them, as the firſt and laſt ſound of any given interval. Sometimes it regards the quickneſs and ſlowneſs of ſuch *motions*, as a briſk, ſlow, lively, or languid *motion*; and in this ſenſe it is uſed with regard to minuets, gavots, ſarabands, &c. See each article in its proper place.

But the moſt common, and indeed the moſt important acceptation of the word, is with reſpect to HARMONY; thoſe above deſcribed only regarding MELODY.

With regard to harmony, it is the comparing the manner wherein an upper or treble part moves from one ſound to another, with that wherein a lower or baſs-part moves; this is to be done three ways. The firſt is when the upper and lower parts both move the ſame way, either upwards or downwards, and is called *moto recto*. The ſecond is when in comparing the upper with the lower part,

the one aſcends while the other deſcends, or *à contrâ*, and hence called *motes contrarii*. The laſt is when one of the parts holds out, or continues a ſound, while the other ſtirs or falls on any note whatſoever; and this is called *mote obliquæ*.

MOTION, in the *ancient Muſic*, was uſed to ſignify the tranſition of the voice, from an acute to a grave ſound; or the contrary. This they expreſſed by κατὰ τόπον ἀνιοῦσα. See LOCUS.

Meibomius tranſlates it, *moveri in loca*.

MOTION is alſo uſed, among *Mechanics*, for the inſide of a watch, &c. more commonly called MOVEMENT.

MOTIONS, in *War*, denote the marches, countermarches, &c. which an army makes in changing its poſt.

The great ſkill of a general conſiſts in diſcovering the enemies *motions*, and concealing his own. Nothing is more dangerous than to make great *motions* before a powerful enemy, ready to come to blows. See MARCH.

MOTION, in the *Manege*. A horſe is ſaid to have a pretty *motion*, when he moves and bends his foreſlegs with great eaſe and freedom upon the manege. But if a horſe trots right out, and keeps his body ſtraight, and his head high, and bends his fore-legs handſomely, then to ſay he has a pretty *motion* with him, implies the liberty of action of the forehead.

MOTION, or EMOTION, in *Rhetoric*. See PASSION.

MOTIONS, *rythmical*, a phraſe uſed by Voſſius, and other writers on the ancient rythm, to expreſs thoſe *motions* which were made uſe of in the Greek and Roman entertainments to convey the ideas of the poet, or to aſſiſt muſic in rouſing the paſſions. Theſe not only had great force when joined with ſounds, but even without any voice or ſound they could move the paſſions in the ſpectators more than many of the beſt orators of the times could do with their moſt laboured diſcourſes.

Roſcius, the ſtage-player ſo famous in their pantomimes, which were all dumb-ſhew, was ſo excellent at expreſſion by theſe *rythmical motions*, or geſtures, that Cicero and he being cotemporaries, there were many diſputes between them, which could vary the ſame ſentence moſt; the one uſing all the power of words, the other being confined to geſtures alone.

MOTION *in court*. In the courts of chancery, king's bench, &c. *motions* are made by barriſters and counſellors at law, for what concerns their clients cauſes; and where any *motion* is made in chancery, that is not of courſe, generally an affidavit of the facts alledged muſt be read in court; and if *motions* are founded on the general rules or uſage of the court, and are not of courſe, but granted or denied as the court thinks fit, on hearing counſel on both ſides, notice is to be given in writing to the ſolicitor of the other party, or his clerk in court, expreſſing every thing to be moved for, which muſt be ſerved two days at leaſt before the day on which the *motion* is to be made; whereof affidavit muſt alſo be made.

MOTIVE is ſometimes applied to that faculty of the human mind, by which we purſue good and avoid evil. Thus Hobbes diſtinguiſhes the faculties of the mind into two ſorts, the COGNITIVE, and *motive*.

MOTORII, MOTORY *nerves*, the third pair of nerves; ſerving for the motion of the eye.

This pair is united into one near their inſertion into the brain; by which means, when one eye is moved towards any object, the other is naturally directed towards the ſame. See NERVES, and EYE.

MOTOS, *uſtus*, a piece of lint, or linen cloth, opened like wool, to be put into ulcers, to ſtop the flux of blood, &c.

MOTOS, in the *Materia Medica of the Ancients*, was a name given by Galen and others to a kind of caſſia bark, the beſt and fineſt that has been uſed at any time. The ancients were very fond of this drug, and ranged it, according to its different goodneſs, into ſeveral ſorts.

MOTRIX, ſomething that has the power or faculty of *moving*.

MOTRIX, *vis*. See VIS *motrix*, and MOTION.

MOTTO, an Italian term, literally ſignifying *word*, or *ſaying*; uſed in arms, devices, &c.

MOTTO *of an armory*, is a ſhort ſentence or phraſe carried in a ſcroll generally over, ſometimes under the arms; ſometimes alluding to the name of the bearer, ſometimes to the bearing, and ſometimes to ſome remarkable atchievement of the bearer.

The *motto*, or word, ſays Guillim, is an external ornament annexed to coat-armour; being the invention or conceit of the bearer, ſuccinctly and ſignificantly expreſſed, uſually in three or four words, which are ſet in ſome ſcroll or compartiment, placed at the foot of the eſcutcheon.

As the *motto* holds the loweſt place in arms, ſo it is the laſt in blazoning. In ſtrictneſs, it ſhould expreſs ſomething intended in the atchievement; but cuſtom has now received whatſoever be the fancy of the deviſer.

The uſe of *mottos* is very ancient; hiſtory, both ſacred and profane, furniſhing inſtances thereof. Our anceſtors made choice of *mottos* to expreſs their predominant paſſions; as of piety, love, war, &c. or ſome extraordinary adventure befallen them; moſt of which, from ſome ſuch original, have become hereditary in divers families.

The *motto* of the royal family of England is, *Dieu & mon droit*; of the royal family of Bourbon, *Eſperance*; of the order of the Garter, *Honi ſoit qui mal y penſe*, &c.

The *motto of a device* is alſo called the *ſoul of the* DEVICE.

MOTU.—*Ex motu* MOTU. See EX.

MOUCHEROLLE, in *Ornithology*, the name of a ſmall bird of the ſize of the ſparrow, and of the ſame colour, but longer bodied; its wings are of a duſkier colour than the reſt of its body, and its head is variegated with very ſmall blackiſh ſpots; its throat and belly are white, but the throat and the ſides of the breaſt and belly have a faint reddiſhneſs; the beak is black, ſtraight and ridged, ſo as to appear triangular; it feeds on flies and other inſects, and is common in gardens and orchards in many parts of England, though it has no Engliſh name. It is confounded by the common people with the common white-throat, but differs from it in that its tail is all of one colour, whereas the white-throat's is variegated. It ſomewhat reſembles alſo the BECCAFICO, or petty-chaps, but differs from it in having no greeniſh colour, and in its bill being ridged and triangular.

MOVE *in arreſt of judgment*. See ARREST.

MOVEABLE, ſomething ſuſceptible of MOTION, or that is diſpoſed to be moved. See MOTION.

A ſphere is the moſt *moveable* of all bodies, i.e. it is the eaſieſt to move; a door is *moveable* on its hinges, the magnetical needle on a pin, or pivot, &c.

Moveable is frequently uſed in contradiſtinction to *fixt*.

MOVEABLE *feaſts* are ſuch as are not always held on the ſame day of the year, or month; though they be on the ſame day of the week. See FEASTS.

Thus, Eaſter is a *moveable* feaſt; being always held on the Sunday which falls upon or next after the firſt full moon following the 21ſt of March. Vide Phil. Tranſ. N° 240, p. 185.

All the other *moveable* feaſts follow EASTER, i. e. they keep their diſtance from it, ſo that they are fixed with reſpect thereto.

Such are Septuageſima, Sexageſima, Aſh-Wedneſday, Aſcenſion-Day, Pentecoſt, Trinity-Sunday, &c. which ſee under their proper articles, SEPTUAGESIMA, &c.

MOVEABLES, or MOVEABLE *goods*, by civilians called *bona mobilia*, are thoſe which are capable of being removed from one place to another; or which may be concealed or perverted; as not being fixed to the ground, &c. See GOODS and CHATTLES.

In England, we have two kinds of effects, *moveable* and *immoveable*: the *moveable* are, ready money, merchandizes, bonds, book debts, cattle, and houſhold furniture, not faſtened either with iron or nail, nor ſealed in the plaſter, but which may be tranſported without either fraction or deterioration.

In the cuſtomary laws, they ſay, *moveables* follow the perſon, and his proper habitation; *moveables* follow the body, &c. which words have different meanings in different countries.

Sometimes they ſignify, that *moveables* go according to the cuſtom of the place where is the habitation of the deceaſed, though he die in another place; and ſometimes they ſignify that *moveables* follow the cuſtom of the place where the deceaſed died.

MOVEMENT, *motion*, a term frequently uſed in the ſame ſenſe with AUTOMATON.

The moſt uſual *movements* for keeping time are *watches* and *clocks*: the firſt are ſuch as ſhew the parts of time, and are portable in the pocket; the ſecond ſuch as perliſh it by ſounds, and are fixed as furniture. See HOROLOGY.

MOVEMENT, in its popular uſe among us, ſignifies all the inner work of a watch, clock, or other engine, which *move*, and, by that motion, carry on the deſign of the inſtrument.

The *movement* of a clock, or watch, is the inſide; or that part which meaſures the time, ſtrikes, &c. excluſive of the frame, caſe, dial-plate, &c.

The parts common to both of theſe *movements* are, the *main-ſpring*, with its appurtenances; lying in the ſpring-box, and in the middle thereof lapping about the ſpring-arbor, to which one end of it is faſtened. A-top of the ſpring-arbor is the *endleſs ſcrew*, and its wheel; but in ſpring-clocks, this is a ratchet-wheel with its click, that ſtops it. That which the main-ſpring draws, and round which the chain or ſtring is wrapped, is called the *fuſy*: this is ordinarily taper; in large works, going with weights, it is cylindrical, and called the *barrel*. The ſmall teeth at the bottom of the fuſy or barrel, which

ſtop

ſtop it in winding up, is called the *ratchet*; and that which ſtops it when wound up, and is for that end driven up by the ſpring, the *gard-goit*. The *wheels* are various: the parts of a wheel are, the *hoop* or *rim*; the *teeth*, the *croſs*, and the *collet*, or piece of braſs ſoldered on the arbor or ſpindle whereon the wheel is rivetted. The little wheels, playing in the teeth of the larger, are called *pinions*; and their teeth, which are 6, 7, 6, 8, &c. are called *leaves*; the ends of the ſpindle are called *pivots*; and the guttered wheel, with iron ſpikes at bottom, wherein the line of ordinary clocks runs, the *pulley*. We need not ſay any thing of the *band*, *ſcrews*, *wedges*, *ſtops*, &c. See WHEEL, FUSE, &c.

MOVEMENTS, *theory of calculating the numbers for*. 1. It is to be obſerved, that a wheel, divided by its pinion, ſhews how many turns the pinion has to one turn of the wheel.

2. That, from the uſe to the balance, the wheels drive the pinions; conſequently, the pinions run faſter, or make more revolutions, than the wheel; but it is the contrary from the great wheel to the dial-wheel.

3. That the wheels and pinions we write down either as vulgar fractions, or in the way of diviſion in common arithmetic: v. gr. a wheel of 60, moving a pinion of 5, is written either $\frac{60}{5}$, or better, 5)60. And the number of turns the pinion has in one turn of the wheel, as a quotient, thus, 5)60(12. A whole *movement* may be written as in the adjoining ſcheme; where the uppermoſt number expreſſes the pinion of report 4, the dial-wheel 36, and the turns of the pin. 9; the ſecond, the pinion, and great wheel; the third, the ſecond wheel, &c. the fourth, the contrat wheel; and the laſt, 12. the crown-wheel.

4	36(9
	5)55(11
	5)45(9
	5)40(8
	12.

Hence, 4. From the number of turns any pinion makes in one turn of the wheel it works in, may be determined the number of turns a wheel or pinion has at any greater diſtance, viz. by multiplying together the quotients; the produce whereof is the number of turns. Thus,

Suppoſe the wheels and pinions as in the caſe adjoining: 11 multiplied by 9, gives 99, the number of turns in the ſecond pinion 5, in one turn of the wheel 55, which runs concentrical, or on the ſame ſpindle with the pinion 5.

5)55(11	
5)45(9	
5)40(8	

Again, 99 multiplied by 8 gives 792, the number of turns the laſt pinion has in one turn of the firſt wheel 5. Hence we proceed to find, not only the turns, but the number of beats of the balance in the time of thoſe turns. For, having found the number of turns the crown-wheel has in one turn of the wheel fought, thoſe turns multiplied by its notches give half the number of beats in that one turn of the wheels. Suppoſe, v. gr. the crown-wheel to have 720 turns, to one of the firſt wheel, this number multiplied by 15, the notches in the crown-wheel, produces 10,800; half the number of ſtrokes of the balance in one turn of the firſt wheel of 80 teeth.

The general diviſion of a *movement* is, into the clock and watch-parts. See CLOCK-*work*, and WATCH-*work*. See alſo TIME-*keeper*.

MOVEMENT, in *Architecture*, is a term uſed by ſome writers to expreſs the riſe and fall, the advance and receſs, with other diverſity of form, in the different parts of a building, ſo as to add greatly to the picturesque of the compoſition. For the riſing and falling, advancing and receding, with the convexity and concavity, and other forms of the great parts, have the ſame effect in architecture, that hill and dale, fore-ground and diſtance, ſwelling and ſinking, have in landſcape; that is, they ſerve to produce an agreeable and diverſified contour, that groups and contraſts like a picture, and creates a variety of light and ſhade, which give great ſpirit, beauty, and effect, to the compoſition.

MOVER, or *firſt* MOVER. See MOBILE.

MOVER, *perpetual*. See *Perpetual* MOTION.

MOULD, or MOLD, in the *Mechanic Arts*, &c. a cavity artfully cut, with deſign to give its form, or impreſſion, to ſome ſofter matter applied therein.

Moulds are inſtruments of great uſe in ſculpture, foundery, &c.

The workmen employed in melting the mineral or metallic globe dug out of mines, have each their ſeveral *moulds*, to receive the melted metal as it comes out of the furnace; but theſe are different, according to the diverſity of metals and works. In gold mines, they have *moulds* for ingots; in ſilver mines, for bars; in copper and lead mines, for pigs or ſalmons; in tin mines, for pigs and ingots; and in iron mines, for ſows, chimney-backs, anvils, caldrons, pots, and other large utenſils and merchandizes of iron; which are here caſt, as it were, at firſt hand.

The MOULDS *of founders of large works*, as ſtatues, bells, guns, and other brazen works, are of wax, ſupported within-ſide by what they call a *core*, and covered without-ſide with a cap or caſe. It is in the ſpace which the wax took up, which is afterwards melted away to leave it free, that the liquid metal runs, and the work is formed; being carried thither through a great number of little canals, which cover the whole *mould*. See FOUNDERY.

The MOULDS *of monyers* are frames full of ſand, wherein the plates of metal are caſt that are to ſerve for the ſtriking of ſpecies of gold and ſilver. See COINING.

A ſort of concave *moulds* made of clay, having within them the figures and inſcriptions of ancient Roman coins, are found in many parts of England, and ſuppoſed to have been uſed for the caſting of money.

Mr. Baker having been favoured with a ſight of ſome of theſe *moulds* found in Shropſhire, bearing the ſame type and inſcriptions with ſome of the Roman coins, gave an account of them to the Royal Society.

They were found in digging of ſand, at a place called Ryton in Shropſhire, about a mile from the great Watling-ſtreet road. They are all of the ſize of the Roman denarius, and of little more than the thickneſs of our halfpenny. They are made of a ſmooth pot or brick clay, which ſeems to have been firſt well cleanſed from dirt and ſand, and well beat or kneaded, to render it fit for taking a fair impreſſion. There were a great many of them found together, and there are of them not unfrequently found in Yorkſhire; but they do not ſeem to have been met with in any other kingdom, except that ſome have been ſaid to be once found at Lyons. They have been ſometimes found in great numbers joined together ſide by ſide, on one flat piece of clay, as if intended for the caſting a great number of coins at once; and both theſe, and all the others that have been found, ſeem to have been of the emperor Severus. They are ſometimes found impreſſed on both ſides, and ſome have the head of Severus on one ſide, and ſome well known reverſe of his on the other. They ſeem plainly to have been intended for the coinage of money, though it is not eaſy to ſay in what manner they can have been employed to that purpoſe, eſpecially thoſe which have impreſſions on both ſides, unleſs it may be ſuppoſed that they coined two pieces at the ſame time by the help of three *moulds*, of which this was to be the middle one.

If by diſpoſing theſe into ſome ſort of iron frame or caſe, as our letter-founders do the braſs *moulds* for caſting their types, the melted metal could be eaſily poured into them, it would certainly be a very eaſy method of coining; as ſuch *moulds* require little time or expence to make, and therefore might be ſupplied with new ones as often as they happen to break.

Theſe *moulds* ſeem to have been burnt or baked ſufficiently to make them hard; but not ſo as to render them porous like our bricks, whereby they would have loſt their ſmooth and even ſurface, which in theſe is plainly ſo cloſe, that whatever metal ſhould be formed in them would have no appearance like the ſand-holes by which counterfeit coins and medals are uſually detected.

MOULDS *of founders of ſmall works* are like the frames of coiners: it is in theſe frames, which are likewiſe filled with ſand, that their ſeveral works are faſhioned; into which, when the two frames, whereof the *moulds* conſiſted, are rejoined, the melted braſs is run.

MOULDS *of letter-founders* are partly of ſteel, and partly wood: the wood, properly ſpeaking, ſerves only to cover the real *mould* which is within, and to prevent the workman, who holds it in his hand, from being incommoded by the heat of the melted metal. Only one letter or type can be formed at once in each *mould*. See *Letter*-FOUNDERY.

MOULDS, in the *Manufacture of Paper*, are little frames compoſed of ſeveral braſs or iron wires, faſtened together by another wire ſtill finer. Each *mould* is of the bigneſs of the ſheet of paper to be made, and has a rim or ledge of wood to which the wires are faſtened. Theſe *moulds* are more uſually called *frames* or *forms*.

MOULDS, *furnace and crucible makers*, are made of wood, of the ſame form with the crucibles; that is, in form of a truncated cone: they have handles of wood to hold and turn them with, when, being covered with the earth, the workman has a mind to round or faſhion his veſſel.

MOULDS *for leaden bullets* are little iron pincers, each of whoſe branches terminates in a hemiſpherical concave, which, when ſhut, form an entire ſphere. In the lips or ſides, where the branches meet, is a little jet or hole, through which the melted lead is conveyed.

MOULDS, *laboratory*, are made of wood, for filling and driving all ſorts of rockets and cartridges, &c.

MOULDS, *glaziers*. The glaziers have two kinds of *moulds*, both ſerving to caſt their lead: in the one they caſt the lead into long rods or canes fit to be drawn through the vice, and the grooves formed therein; this they ſometimes call *ingot-mould*. In the other they *mould* thoſe little

little pieces of lead a line thick, and two lines broad, fastened to the iron bars. These may be also cast in the vice.

MOULDS, *goldsmiths*. The goldsmiths use the bones of the cuttle-fish to make *moulds* for their small works; which they do by pressing the pattern between two bones, and leaving a jet or hole to convey the silver through, after the pattern has been taken out.

MOULD, among *Masons*, is a piece of hard wood or iron, hollowed within-side, answerable to the contours of the mouldings or cornices, &c. to be formed. This is otherwise called *caliber*.

MOULDS, among *Plumbers*, are the tables whereon they cast their sheets of lead. These they sometimes call simply *tables*. Besides which, they have other real *moulds*, wherewith they cast pipes without soldering. See each described under PLUMBERY.

MOULDS, among the *Glass-Grinders*, are wooden frames, whereon they make the tubes wherewith they fit their perspectives, telescopes, and other optic machines.

These *moulds* are cylinders, of a length and diameter according to the use they are to be applied to, but always thicker at one end than the other, to facilitate the sliding. The tubes made on these *moulds* are of two kinds; the one simply of pasteboard and paper; the other of thin leaves of wood joined to the pasteboard. To make these tubes to draw out, only the last or innermost is formed on the *mould*; each tube made afterwards serving as a *mould* to that which is to go over it, but without taking out the *mould* from the first. See GRINDING.

MOULDS used in basket-making are very simple, consisting ordinarily of a willow or osier turned or bent into an oval, circle, square, or other figure, according to the baskets, panniers, hampers, and other utensils intended. On these *moulds* they make, or, more properly, measure, all their work; and, accordingly, they have them of all sizes, shapes, &c.

MOULD, in *Ship-Building*, a thin flexible piece of timber, used by shipwrights, as a pattern whereby to form the different curves of the timbers, and other compassing pieces, in a ship's frame. There are two sorts of these, viz. the *bend-mould* and *bollen-mould*: the former of these determines the convexity of the timbers, and the latter their concavity on the outside, where they approach the keel, particularly towards the extremities of the vessel. The figure given to the timbers by this pattern is called their BEVELLING.

MOULDS, among *Tallow-Chandlers*, are of two kinds: the first for the common dipped candles, being the vessel wherein the melted tallow is disposed, and the wick dipped.

This is of wood, of a triangular form, and supported on one of its angles, so that it has an opening of near a foot at top: the other, used in the fabric of *mould* candles, is of brass, pewter, or tin. Here each candle has its several *moulds*. See each under CANDLE.

MOULD, among *Gold-Beaters*, a certain number of leaves of vellum, or pieces of guts, cut square, of a certain size, and laid over one another, between which they put the leaves of gold and silver which they beat on the marble with the hammer. See GOLD-*leaf*.

They have four kinds of *moulds*; two whereof are of vellum, and two of gut: the smallest of those of vellum consists of forty or fifty leaves; the largest contains a hundred: for the others, each contain five hundred leaves.

The *moulds* have all their several cases, consisting of two pieces of parchment, serving to keep the leaves of the *mould* in their place, and prevent their being disordered in beating.

MOULD, or MOLD, in *Natural History*, that kind of earth every where obvious on the surface of the ground; called also natural or mother earth. See EARTH and LOAM.

Moulds are defined by Dr. Hill to be earths composed of dissimilar particles of a loose soft texture, somewhat ductile while moist, composed of argillaceous particles separated by sand or the grit of stone, and usually found mixed with the putrefied remains of vegetable and animal substances.

Of this class of bodies there are two genera: 1. The thruttomicthes, or *moulds* of a lax friable texture; and, 2. The gloiomicthes, which are of a more tough and viscid texture. Of these there are several species; viz. the red and friable brown of the first, and the greyish-brown and heavy yellowish-brown of the second.

Moulds, according to Mr. Da Costa, are compound earths, of a loose soft texture, somewhat ductile while moist, and composed of earthy particles, mixed with the putrefied remains of animal and vegetable bodies. He distinguishes them by their colours into the black, not acted upon by acids, to which belongs the common vegetable *mould*, or garden earth; the red, which is alkaline; and the brown, some of which are not acted upon by acids, and others alkaline.

The goodness of *mould*, for the gardener's purposes, is known by the sight, smell, and touch.

Those *moulds* are accounted best which are of a bright brown, or hazel colour. This is always the colour of the best loams, and other natural earths; and this is judged the better, if the earth cut tolerably easy, and does not stick and cling to the spade, but is light, friable, and falls into small clods; and is such as naturally neither chaps and cracks in dry weather, nor turns to mortar in wet. Next to these the dark grey and russet *moulds* are accounted best; and the worst of all are the light and dark ash-colour; these are usually found on heaths and commons. The clear tawny *mould* is not by any means to be preferred; but that of a yellowish red is accounted the worst of all: this is commonly found in wild and waste places, and seldom produces any thing naturally but furze and fern.

All that lands give us to judge of them by from the smell is, that the best after rain, and after digging up, emit a good and pleasing scent. But by the touch they may be judged of with considerable accuracy; for by this may be known whether they are too sandy or too clayey; and whether they be tender, fatty, detersive, and slippery; or more harsh, gritty, porous, and friable. What we are to judge best by the touch, is the middle nature between the extremes on either side, such as will easily dissolve and break, and being made of a just proportion of sand and clay, will not stick to the spade or fingers after every light shower of rain. Miller.

To analyse *mould* by means of water, wash it thoroughly in warm water in large quantities, and filtrate the liquor. Evaporate this to a considerable degree of concentration, and it is manifestly of a saline taste, but making no alteration in syrup of violets; therefore the salt it contains is neither acid nor alkaline, but neutral. This analysis pursued farther, the particles may be disunited and kept separate, and will be found to be a large proportion of sand, a quantity of a light mud, capable of remaining a long time suspended in water, and a heavier mud sinking immediately in water. By an analysis of any particular *mould* by this means, we may find its true constituent particles, and be able to mix up and compound a similar one for the growth of any peculiar plant it produces. But plants have the assistance of heat as well as moisture, in the drawing their juices from the earth; therefore it may not be improper to try the effect of fire on the same subject. The common garden *mould* distilled in a retort in a naked fire, managed in its various degrees, affords a water, and oil and spirit like those yielded by animal subjects, and possibly arising from some extraneous particles mixed with the earth, and a dry *caput mortuum*, or indolent earth, remains in the retort.

The particles of animal, vegetable, and mineral substances, floating in the atmosphere, and thence precipitated on the earth, may give some of the properties to garden *mould*, and those different in different places; as is evident about London, where the *mould* is so impregnated with smoak, precipitated on it from the atmosphere, that it differs much from that of open countries. Shaw's Lectures, p. 64.

MOULD, *hip*. See HIP-*mould*.

MOULD, *iron*. See IRON-*mould*.

MOULDINESS, a term applied to bodies which corrupt in the air, from some hidden principle of humidity therein; and whose corruption shews itself by a certain white down, or lanugo, on their surface.

This *mouldiness*, when viewed with a microscope, affords a curious spectacle; being a kind of meadow, out of which arise herbs and flowers; some only in the bud, others full blown, and others decayed; each having its little root, stalk, and other parts; the figure whereof may be seen in Hook's Micrographia. The same may be observed of the *mouldiness* which gathers on the surface of liquid bodies.

Mr. Bradley observed this *mouldiness* in a melon very accurately, and found the vegetation of these little plants to be exceedingly quick. Each plant had its seeds in great abundance, which did not seem to be three hours before they began to shoot up; and in six hours more the new plant was complete and mature, and the seed ready to fall. When the fruit had been covered with a mould for six days, its vegetative quality began to abate, and it was entirely gone in two days more; then came on a putrefaction, and the fleshy parts of the melon yielding nothing but a stinking water, which began to have a gentle motion on its surface; and in two days time maggots appeared, which in six more laid themselves up in their bags, where they continued four days, and then came out flies. These maggots were owing to the eggs of flies deposited in the putrefaction.

MOULDING, any thing cast in a mould, or that seems to have been so, though in reality it were cut with a chissel, or the ax.

MOULDINGS, in *Architecture*, are jettings, or projectures beyond the naked of a wall, column, wainfcot, &c. the aſſemblage whereof form cornices, door-caſes, and other decorations of architecture. See *Tab. Architect. fig.* 1. to 12.

Some *mouldings* are ſquare, others round; ſome are ſtrait, others curved, &c. and ſome are plain, others carved, or adorned with ſculpture, either hollowed or in relievo.

Some *mouldings*, again, are crowned with a fillet; others are without, as the doucine, talon, orolo, torus, plinth, ſcotia, aſtragal, gula, corona, and cavetto. See each under its proper article.

Mouldings are in architecture what letters are in writing. By the various diſpoſitions and combinations of *mouldings*, may be made as infinite number of different profiles for all ſorts of orders and compoſitions, regular and irregular; and yet all the kinds of *mouldings* may be reduced to three; viz. ſquare, round, and mixt, i. e. compoſed of the other two.

For this reaſon, thoſe who invented the Gothic architecture, reſolving to recede from theſe perfect figures, and affecting to uſe others leſs perfect, to diſtinguiſh their architecture from the antique, introduced a new ſet of whimſical *mouldings* and ornaments.

Regular *mouldings* are either *large*; as doucines, ovolos, gulas, talons, toruſes, ſcotias, &c. or *ſmall*, as fillets, aſtragals, conges, &c. which ſee in their places.

MOULDINGS, in *Gunnery*, are annexed to guns by way of ornament, and depend chiefly on the maker's fancy.

It may be obſerved in general, that they ſhould be plain and ſimple, and the metal ſhould be projected as little as poſſible, ſo that the piece may lie cloſe on the carriage. See GUN. and *Tab. Gunnery, fig.* 1. n. and *o*.

MOULDING, *bed*. See BED-*moulding*.

MOULDING, *plane*. See PLANE.

MOUL-ELAVOU, *ſive arbor lanigera ſpinoſa*. H. M. *Goſſypium arboreum ſecundum ſpinoſum*. C. B. is a fine, tall, lanigerous, or cotton-bearing tree, ſometimes no leſs than fifty feet in height, and eighteen in compaſs in the ſtem or trunk. The down, or cotton, ſerves to ſtuff beds and pillows: the bark of the tree pulveriſed, and with the juice of lemons reduced into the form of a liniment, mitigates all kinds of inflammations, and conſolidates fractures of the bones; mixed with burnt wine of the Indian nut, or cocoa, it makes a liniment for the herpes: of the bark of the root is prepared an excellent emetic: the ſweet liquor collected in the boſom of the flower, exhibited with the leaves of the tamarind, potently evacuates watery humours by ſtool and urine. Ray.

MOULIN. *Fer de* MOULIN. See FER.

MOULINET, a French term properly ſignifying a little mill, being the diminutive of *moulin, mill*.

It is uſed in mechanics to ſignify a roller, which, being croſſed with two levers, is uſually applied to cranes, capſtans, and other ſorts of engines of the like nature, to draw ropes, and heave up ſtones, timber, &c.

MOULIRET is alſo a kind of turn-ſtile, or wooden croſs, which turns horizontally upon a ſtake fixed in the ground; uſually placed in the paſſages to keep out horſes, and to oblige paſſengers to go and come one by one.

Theſe *mouliets* are often ſet near the outworks of fortified places, at the ſides of the barriers, through which people paſs on foot.

MOULLAVA, H. M. in *Botany*, a ſiliquous Indian plant, with a yellow, pentapetalous flower, and a ſmooth pod, containing generally four ſeeds. It grows to the height of eight or nine feet, and delights in ſandy places; it is an evergreen, flouriſhes moſt in a wintry ſeaſon, and the fruit is ripe in November and December. It is of no medicinal uſe, but only to the poſſias (ſo they call the poor in thoſe countries), who receive the ſmoke of the leaves up their noſtrils, and ſo cure themſelves of the head-ache and vertigo. Ray.

MOULTING, in *Natural Hiſtory*. See MOLTING.

MOUND, a term uſed for a bank, rampart, or other fence, particularly of earth.

MOUND, or MOND, in *Heraldry*, is a ball or globe with a croſs upon it; ſuch as our kings are uſually drawn with, holding it in their left hand, as they do the ſceptre in the right.

MOUNT, an elevation of earth, called alſo *mountain*.

The words *mount* and *mountain* are ſynonymous; but the former is ſcarce ever uſed in proſe, unleſs when accompanied with ſome proper name; as *mount* Ætna, *mount* Gibel, *mount* Lebanon, *mount* Sinai, *mount* Atlas, *mount* Parnaſſus, &c.

MOUNT *Sinai, St. Catharine of*. See CATHARINE.

MOUNT *Carmel, knights of*. See CARMEL.

MOUNTED, in *Sea Language*, the ſtate of being armed or equipped with a certain number of cannon; expreſſed of a veſſel of war.

MOUNT-*up*. In the tin-works, after that tin from the burnt ore is melted down, and re-melted, there will ſometimes remain a different ſlag in the bottom of the float; this they call *mount-up*; and though of a tin-colour, yet it is of an iron nature, as hath been found by applying a magnet to it.

MOUNT *guard*. See GUARD.

MOUNTS *of piety*, are certain funds, or eſtabliſhments in Italy, where money is lent out on ſome ſmall ſecurity. We had alſo *mounts of piety* in England, raiſed by contribution for the benefit of people ruined by the extortions of the Jews.

MOUNTAIN, MONS, a part of the earth riſing to a conſiderable height above the level of the ſurrounding ſurface.

The origin of *mountains* is variouſly aſſigned by philoſophers; ſome will have them coeval with the world, and created along with it.

Others, among whom is Dr. Burnet, will have them to take their riſe from the deluge; urging, that the extreme irregularity and diſorder viſible in them plainly ſhew they do not come immediately out of the hand of God, but are the wrecks of the old world broken into the abyſs.

Others, again, alledge from hiſtory, that the foundations of many hills being gradually deſtroyed, the hills themſelves have ſubſided, and ſunk into plains: whence they conclude, that where the corruption is natural, the generation is ſo too.

It appears to many, that ſome *mountains* muſt have been generated gradually, and have grown up in proceſs of time, from the ſea-ſhells, &c. found in many of them; which they ſuppoſe may be accounted for from a violent wind blowing the ſand, &c. into huge heaps, which are afterwards made into a maſs by the rain, &c. Some among the divines tell us, that the earth was created perfectly even; and that when God ſeparated the water from the land, he dug channels in the earth; and the earth ſcooped out he threw up in *mountains*: but whether all the *mountains* be ſufficient to fill all the channels of the ocean, they muſt decide.

The origin of *mountains*, according to Mr. Ray, ſeems to have been explofions by means of ſubterranean fires; and it is very probable that they have all vaſt hollows beneath them; that this might have been the means uſed at the creation, to make the dry land appear, is no way diſſonant to reaſon, ſince hiſtory proves, that fires have raged in ſubterranean caverns under the ſeas, and there is no natural impoſſibility in fire's ſubſiſting in ſuch caverns, even when the earth was all over covered with water, as at the firſt creation.

Mr. Le Cat, in his memoirs read in 1744, before the academy of Rouen, has delivered a new ſyſtem of the formation of *mountains*. He ſuppoſes, that in the beginning the ſubſtances of which metals, ſtones, earth, &c. were to be formed, were ſoft maſſes of a kind of mud; that theſe arranged themſelves according to their ſpecific gravity, forming regular ſtrata of a ſpherical or ſpheroidical figure, and covered with water; ſo that the ſurface of the earth was originally regular, or without the inequalities of hills and vallies. But afterwards, by reaſon of the action of the ſun and moon, theſe ſoft maſſes were variouſly driven into enormous maſſes or *mountains* of mud, which left in their interſtices vallies, whoſe capacities, receiving vaſt quantities of water, left part of the earth expoſed and dry, and contributed to form a continent, which has gradually increaſed by the ſame alternate motions. By the continuance of this excavation of the earth, by means of the flux and reflux of the ſea, and the augmentation of the land thrown up by them, all the vaſt tracts of Europe, Aſia, &c. which were originally covered with water, became ſucceſſively expoſed and habitable. Theſe waters have left on the ſurface of the earth, ſkeletons, both of thoſe animals which lived in them, and of thoſe terreſtrial animals which may be ſuppoſed to have periſhed in theſe fluctuations. What the flux and reflux of the ſea has performed from the beginning, is ſtill continued, though in a leſs ſenſible manner. The materials of the earth being more compact and ſolid, the ſea is continually excavating its bed, and throws upon the banks the ſtones and earth which it forces away from its bottom. At length by this continued retreat of the ſea and excavation of the earth, he ſuppoſes that this globe will be ſo undermined as to produce a confluence of the ſeas from hemiſphere to hemiſphere; in conſequence of which a new chaos will take place; and a new world will be formed out of the ruins of the old.

Mountains appear, to many, defects and blemiſhes in the earth; but they are truly of the utmoſt uſe and neceſſity to the well-being both of man and other animals. Many creatures cannot live but in particular ſituations, and even the tops of the higheſt and the coldeſt *mountains* are the

only places where some creatures, as well birds as quadrupeds, will live: of this kind are the ibex and chamois among beasts, and the lagopus among birds.

They serve as screens to keep off the cold and nipping blasts of the northern and eastern winds; they also serve for the production of a great number of vegetables and minerals, which are not found in any other soil; they enable us to keep those mines dry, which furnish the most useful metals; besides, the long ridges and chains of lofty and jagged *mountains*, being generally found to run from east to west, serve to stop the evagation of the vapours towards the poles, without which they would all run from the hot countries, and leave them destitute of rain.

Mr. Ray adds, that they condense those vapours, like alembic heads, into clouds; and so by a kind of external distillation, give origin to springs and rivers; and, by amassing, cooling, and condensing them, turn them into rain; and, by that means, render the torrid regions of the torrid zone habitable. Thus the more we consider nature, the more we must admire her works; and what seems to be a defect or blemish in them, on a slight view, often proves, on more just observation, a great benefit and beauty.

In history we have instances of *mountains* travelling considerable distances.

To measure the height of a *mountain*, see ALTITUDE, &c. Though there is another way used by Dr. Halley, in the measure of Snowdon hill in Wales, by means of a BAROMETER, the different heights of whose mercury at the top and bottom of the *mountain* give its perpendicular altitude; accounting eighty-two feet perpendicular ascent for every inch varied in the height of the mercury.

The method often used for measuring the heights of *mountains*, by the sinking of the mercury in the barometer, is very far from being accurate in practice. That the mercury generally falls, when the barometer is carried up to a higher ground is true, and has been known ever since the time of Pascal. The only question is, in what proportion? and this question is not yet determined with sufficient accuracy. The rule followed by the generality of authors, is, that the heights of *mountains*, or other rising grounds, are as the logarithms corresponding to the heights of the mercury in the barometer. And the foundation of this rule is, that the density of the air is every where proportional to the weight of the superincumbent air. But the application of this principle is improper in the present case, because it can hold true only when the air is of the same degree of heat, which it seldom is, on the different parts of high *mountains*, in the valleys, and at the surface of the sea. In ascending the Cordelieras of Peru, for instance, the air is found to be of all temperatures, from the hottest summer to the coldest winter. And experiments are directly contrary to the rule. For by father Feuillee's observations on the Pic of Teneriffe, the mercury in the barometer stood at 17 inches 5 lines Paris measure, at the height of 13158 Paris feet above the surface of the sea, when the barometer at that surface stood at 27 inches 10 lines. But, according to the rule above mentioned, the barometer on the Pic ought to have been above 2 inches 2 lines lower than what it was found to be by the experiment.

A difference may also be perceived between the computed and observed heights of the barometer, at much smaller elevations; such as 1548 feet; where the observed height of the mercury exceeded that found by computation above a line and a half; which would make a very considerable error in the height of the place.

From whence it follows, that the elasticity or spring of the air at different heights, is not proportional to its density, or, which amounts to the same thing, that the mean degree of heat is different at different heights from the surface of the earth; for it is well known, that a difference of heat will make a difference of elasticity in the air, its density remaining the same. See Daniel Bernoulli Hydrodynamic, p. 213.

This learned author observes, that father Feuillee's experiment on the Pic of Teneriffe overturns all the rules and hypotheses hitherto contrived for discovering the heights of places, from the fall of mercury in the barometer. Mr. Bernoulli has given a new hypothesis of his own, and has founded some computations on it, which agree pretty well with the experiments he mentions; but it were to be wished that this subject were re-examined with more care by a greater variety of experiments than has been done hitherto.

Monf. Caſſini de Thuri has given us a detail of ſeveral obſervations made with care on two high *mountains* of Auvergne, and upon the *mountain* Canigou, one of the highest of the Pyrenees. From theſe obſervations it appears, that the variations of the heights of the mercury in the barometer, correſponding to the elevation of places above the level of the ſea, follow no regular progreſſion; there having been found ſometimes an inch of difference between the height of the mercury found by obſervation on the *mountain* Canigou, from the height that reſulted from the progreſſion eſtabliſhed in the Memoirs of the Royal Academy in 1703. This progreſſion, being deduced from obſervations made at ſmall elevations, proved erroneous; nor have any of the hypotheſes made ſince been ſufficient to reconcile the irregularities in obſervations, the exactitude of which admits of no doubt. Mem. Acad. Scienc. 1740. p. 94.

On this ſubject, ſee M. de Luc's elaborate and excellent work, entitled Recherches ſur les Modifications de l'Atmoſphere, in two volumes 4to. Geneva, 1772: and Phil. Tranſ. vol. lxvii. part 2. art. 29. vol. lxviii. part 2. art. 32.

The difficulty of breathing at the tops of high *mountains* is a thing ſo plainly felt, that there are none who have ever been in the way of making the experiment, who are not well convinced of the certainty of the fact. Acoſta deſcribes what he felt on the tops of the high *mountains* of Pariacaca very judiciouſly. See AIR.

The *mountains* of Armenia, and particularly that on which Noah's ark is ſuppoſed to have reſted, have been alſo made famous by the like accounts; though the ſnows that lie on the tops of theſe *mountains* make it impracticable to aſcend their tops; the people who climb as high as they can, always find that they breathe with more difficulty, and are compelled to fetch their breath oftener than when on the plains; and on travellers complaining of this, their guides always tell them, that it is a known thing, and is what every body ſuffers there.

The *mountains* in Languedoc and the Pyrenees have the ſame effect. People of curioſity have ſometimes remained hours on the ſummit of theſe *mountains*, and always found the ſame ſort of difficulty in breathing; but it is poſſible that this may be owing to the exhalations of certain ſteams from the earth in theſe places, leſs loaded with a weight of air than below; and this appears the more probable, as in going up the *mountain* Teneriffe, if many people are in company, and aſcend different ways, ſome uſually bear it better than others; and the very complexions of ſome are turned yellow by the exhalations, which are very plainly perceived by their ſmell and thirſtneſs, while others, who aſcend to the ſame height by different tracts, eſcape.

The moſt remarkable *mountain* in the world, in ſhape, is that called the *needle mountain*, or the *inacceſſible mountain*, in Dauphiny.

This is a vaſt hill, placed as it were bottom upwards, or ſet on its ſummit on the earth with its broad baſe elevated in the air; it is about a thouſand paces in circumference at the bottom, and is above two thouſand at the top. On the center of the plain at the top there ſtands another ſmall and very narrow, but very high hill.

It obtained the name of the *needle*, as it got the other, by its being ſuppoſed impracticable to the aſcent of any one, by reaſon of its projecting ſo greatly outwards. Some hardy perſons, however, once ventured to climb it, and found at the top a number of the chamois, animals by no means qualified for climbing, and which doubtleſs had never either aſcended or deſcended the *mountain*, and which muſt be ſuppoſed to have bred there for many ages, though it is very difficult to account for their firſt getting to the place. Hiſt. Acad. Par. 1700.

MOUNTAINS, *attraction of*. See ATTRACTION.

MOUNTAINS, *chains of*, a term uſed by geographers to expreſs thoſe continuations of *mountains* which run in ridges along whole countries, and appear diſpoſed in uninterrupted orders wherever they are found. Kircher, in his *Mundus Subterraneus*, labours to prove, that theſe chains are annular, and reach abſolutely round the globe of the earth, encompaſſing it from north to ſouth, and thence to the north again; and in the ſame manner from eaſt to weſt, and from thence to the eaſt again; their courſe only diſappearing, by the wiſe proviſence of nature, in the bottoms of the ſea, that the immenſe body of waters treaſured there might have its motion free and unimpeded in its channel, but appearing again in the ſame line, in every the ſmalleſt iſland that ſhews itſelf in the way of their ſtraight courſe, from the country where the laſt link of the chain was ſeen, to that where their firſt link appears again. He ſays, that theſe vaſt hills of earth and ſtone ſerve not only to ſtrengthen and ſupport the fabric of this vaſt globe of earth, but they have another very great uſe, not only to man, but to all animals, and even vegetables; which is, that they are the ſtore-houſes, where the grand reſervoirs of freſh water, ſo neceſſary to all life, are treaſured up, and from whence it is eaſily poured down upon the lower parts of the globe. In Europe, the great reſervoirs of water, that ſupply whole countries

countries of immenſe extent, are placed in that vaſt chain of *mountains* called the Alps, from which, as from an inexhauſtible ſtore, the vaſt tracts of fruitful land that lie below them are ſufficiently watered.

The *mountains* which compoſe this part of the great annular chain running north and ſouth round the globe, are called by three different names; the *Cottian*, the *Rhætian hills* with the *Vogeſus*, and the *Appennines*. From theſe are poured out the immenſe rivers which water this fruitful part of the world, the Danube, the Rhine, the Rhone, the Moſelle, and an almoſt infinite number of others, every one of which, after it has ſupplied the inhabitants of a whole tract of vaſt extent, diſcharges ſo much water hourly into the ſea, that the mind is aſtoniſhed at the account, and would wonder whence only one of them could be ſupplied. Theſe rivers, and a multitude of other ſmaller ones, and beſides theſe a great number of lakes of vaſt extent, are all ſupplied by the hydrophylacia or reſervoirs of water treaſured up in the boſoms of theſe hills, and could not have performed their office of watering theſe extenſive countries, had thoſe reſervoirs been placed any where except in ſuch a lofty ſituation in theſe *mountains*.

The Alps, though they all ſupply more or leſs of this profuſion of water, yet they are not equally hollowed for the reception of it, and conſequently do not all contain ſupplies for an equal tract of land; this is provided for by nature by a vaſt number of other ſmaller *mountains*, which in ſeveral parts of the countries through which this chain paſſes, run from its ſides like leſſer knots, and extend over ſome ſmaller or greater part of the country.

Theſe are a ſort of auxiliary ſupplies, and ſerve for many countries in the place of the original heads; but the rivers propagated from theſe, though ſufficient for the occaſions of the inhabitants of the lower country, yet do not diſcharge thoſe vaſt quantities of waſte water into the ſea, that thoſe which derive their origin from the greater *mountains* do. The Noric *mountains* in Germany, the Vogeſus, many *mountains* in Dauphiny, and thoſe in Italy, which run from the ſides of that long chain, which reaches like a ſpine all along that country, are all of this kind, and all convey this benefit to the lower countries. The Pyrenean and Carpathian *mountains* alſo yield a vaſt number of rivers from their ſides; and the rivers of Spain, of Poland, and of Hungary, all have evidently the ſame origin from theſe high-ſeated reſervoirs, in the chains of *mountains* which paſs through them. The countries where extended plains are found for vaſt tracts, uninterrupted by any of the links or knots of theſe vaſt chains of *mountains*, are the only places where thirſt and drought are the deſtruction both of animals and plants; and, in general, that country which has moſt and higheſt *mountains*, is the moſt plentifully, moſt regularly, and moſt conſtantly watered by ſmaller as well as larger ſtreams.

The diſpoſition of *mountains* on the ſurface of the globe ſeems more regular than is generally ſuppoſed by thoſe who ſee but a few of them in particular countries at a time; they are diſpoſed in reality in ranges or chains, reaching to vaſt extents, and in ſome from pole to pole, from north to ſouth.

One grand chain of *mountains* reaches from Iceland through Scotland, England, and Germany, with a ſtraight courſe to the Alps, which are as it were a vaſt knot in this chain, more cloſely diſpoſed, and more eminent than the others.

Theſe are ſucceeded in the ſame ſeries by the Appennines, which run through the whole kingdom of Italy, in the manner of the ſpine of the back in animals, and are continued on in the ſame ſeries by thoſe of Sicily; and from theſe the ſame chain is carried on to Africa, and continues in what are called the *mountains of the moon*. From hence another vaſt knot or link of this extenſive chain is carried on to the utmoſt part of Africa, and terminates, as to our view, at the Cape of Good Hope; and there is no reaſon to doubt but that the chain is continued in the oppoſite land, and ſo on to the utmoſt limits of the ſouthern pole. From hence the ſame ſeries makes its way again, and beginning anew as it were from the ſouth pole, is carried on through the little known ſouthern regions to the Magellanic Streights. Here the famous Andes, *mountains* of South America take it up, and along this vaſt tract it is carried through this part of the new world into North America, and thence to the northern pole again, terminating where it began, or joining the other part of the chain where we took up the beginning of our account; ſo that the whole ſeries, making a vaſt belt or circle round the globe, has no beginning nor end, but in our imagination, or in our ignorance of the parts of the world through which it is carried in the ſame regularity as in thoſe countries whither commerce has led us, and where maps have ſhewn them.

Another vaſt chain of *mountains*, running with the ſame regularity, and in the ſame manner forming a belt round the whole globe of the earth, cuts this at right angles, and is continued in its courſe. This goes through Tartary, from a beginning far beyond our reſearches up behind that vaſt country, and continuing itſelf through the middle of Scythia, forms a ſeries that appears in the Eaſt Indies, running along the middle of that vaſt region to Cape Comorin; here the chain dips into the ſea; but if its courſe is exactly marked it will be found to be continued in the ſame route through the iſland of Ceylon; hence it is carried under water to its oppoſite point on the limits of the earth, and hence through ſeas and lands not yet known to us, is carried on to the place in the back of Tartary, and from which we have begun the account. We have but very ſmall proofs indeed of its continuation through a vaſt tract of this its courſe; but we are to accuſe for this defect not nature in her diſpoſal, but our own ignorance, whatever little we do know plainly pointing out, that this chain is continued in the ſame regular manner as the other, and placed exactly at right angles with it.

As the continual flux and reflux of that vaſt body of ſeas from the eaſt weſtward, might by its force do ſome miſchief to the compages of the earth, *provident* nature has provided, for the ſtrengthening the great frame of this globe, certain tranſverſe chains of belts of mountains, which are ſo diſpoſed as to ſtrengthen and keep together the whole machine in the moſt ſtrong and laſting manner.

One ſeries of theſe runs directly from the eaſt weſtward from the utmoſt limits of the Chineſe empire, through that whole vaſt country; and where theſe are ſtopped by the boundaries of that country, they are continued through the weſt of Scythia, India, and the Caſpian ſea, America, Aſia Minor, Macedonia, and to the Rhætian *mountains*, which carry on the chain to the *mountains* of Narbonne Gaul, and theſe to the Pyreneans; and theſe are carried on weſtward in the ſame direct chain, ſo far as we are able to trace them, and apparently run on toward the point from which the account began, ſo as to form as regular a circle as the others, were every link of it expoſed to our ſight, by our knowledge of the regions through which it paſſes, and many of which are yet left to future diſcoveries.

Thoſe who haſtily judge of this ſyſtem may ſuppoſe, that it wants due weight, becauſe the chains of *mountains* here deſcribed do not appear to be regularly carried on through the bottom of the ſea from the firſt link on one land to the firſt on the oppoſite land to it; but the whole chain ſeems broken abruptly at either promontory, and only to be renewed, not continued at the other; but it is very probable, that, though not ſo evident to our eyes, theſe chains of *mountains* are continued under the bottoms of the deepeſt ſeas in the ſame regular manner as on the openeſt land, though their heads do not appear above the ſurface of the water, but are only ſeen at thoſe places where the ſcattered iſlands happen in their courſe, till they arrive at the main land again. This diſpoſition is not to be ſuppoſed owing to chance or irregularity, but appears contrived by the wiſdom of the great Creator.

The vaſt body of ſeas, that ſurrounds the globe with its neceſſary and perpetual flux, required a clear and free bed to roll its immenſe congeries of water in; and the tops of the *mountains* appear to have been diſcontinued in the courſe of this fluid, that it might have a free channel, and no ſtops or hindrances in its courſe, to ſpread its waters over the whole earth.

MOUNTAIN, *cock of the*, *urogallus*, in *Ornithology*. See COCK and GROUSE.

MOUNTAIN-*green*. See GREEN.

MOUNTAIN-*heath*, the name by which ſome call the SAXIFRAGE of botanical writers.

MOUNTAINS, *burning*. See VOLCANO.

MOUNTAINS *in the moon*. See MOON.

MOUNTEBANKS, derived from the Italian *montare in banco*, are quack doctors or jugglers, who vend their boaſted medicines and exhibit their tricks on a public ſtage. See NUISANCE.

MOUNTING *the guard*, *trenches*, *breach*, *&c.* denotes the going upon duty, being upon guard in the trenches, running to the breach, *&c.*

MOUNTING *a cannon*, *mortar*, *&c.* is the ſetting it on its carriage, or the raiſing its mouth.

MOUNTING, *in the Manufactories*, ſomething that ſerves to raiſe or ſet off a work. Thus the frame or border, and its dependencies, make the *mounting* of a looking-glaſs: the *foil*, or but, the *mounting* of a muſquet, cartine, *&c.* and the hilt, *&c.* the *mounting* of a ſword.

MOUNTING *of a fan*, the ſticks which ſerve to open and ſhut

shut it, whether they be of wood, ivory, tortoise-shell, whalebone, Indian-cane, or the like. See FAN.

MOURAILLE, in *Farriery*. See BARNACLES.

MOURNING, a particular dress or habit, worn to signify grief, on some melancholy occasion.

The modes of *mourning* are various in various countries; as are also the colours that obtain for that end. In Europe, the ordinary colour for *mourning* is black; in China, it is white; in Turkey, blue or violet; in Egypt, yellow; in Ethiopia, brown. The ancient Spartan and Roman ladies mourned in white; and the same colour obtained formerly in Castile, on the death of their princes. Herrera observes, that the last time it was used, was in 1496, at the death of prince John. Kings and cardinals always mourn in purple.

Each people pretend to have their reasons for the particular colour of their *mourning*: white is supposed to denote purity; yellow, that death is the end of human hopes, in regard leaves when they fall, and flowers when they fade, become yellow; brown denotes the earth, whither the dead return; black, the privation of life, as being the privation of light; blue expresses the happiness which it is hoped the deceased does enjoy; and purple, or violet, sorrow on the one side, and hope on the other, as being a mixture of black and blue.

Mourning among the ancients, was expressed various ways, as by tearing their cloaths, by wearing slackcloth, laying aside crowns, and every other mark of joy. Plutarch, in his life of Cato, relates, that from the time of his leaving the city with Pompey, he neither shaved his head, nor, as usual, wore the crown or garland.—Sometimes public grief was testified by a general FAST. Among the Romans a year of *mourning* was ordained by law, for women who lost their husbands.

In public *mournings* at Rome the shops were shut up, the women laid aside all their ornaments, the senators their laticlavian robes, and the consuls sat in a lower seat than usual.

The ancients had a remarkable way of *mourning* for soldiers slain in battle. The whole army attended the funeral solemnities, with their arms reversed, it being customary for mourners, in most of their actions, to behave themselves in a manner contrary to what was usual at other times. In those places where it was the fashion to wear long hair mourners were shaved; and where others shaved, mourners wore long hair. The conjecture of those, therefore, is frivolous, who imagine that the soldiers turned the heads of their shields downwards, lest the gods, whose images were engraved upon them, should be polluted with the sight of a corpse; since not the gods only, but any other figures, were frequently represented on shields; nor did the few only near the corpse, but the whole company held their shields in the same position: not to mention that other arms were also pointed downwards. Potter, Archæol. Græc. tom. ii. p. 103.

The *mournings* of the Eastern nations of Indians are much more closely followed, though of much shorter duration than our's. After the death of a near relation they mourn fifteen days, during which time they eat nothing but rice and water: they are not to chew betle, or to use the common washings in this time; but they are to do acts of charity, such as distributing food to the poor; and prayers are said, intreating the Almighty to forgive the sins of the dead person, and assign him a good place in the other world. On the fifteenth day, that is the day after the finishing of the time of *mourning*, they make a solemn feast according to their abilities, and invite to it all their friends and neighbours. After this they annually, on this day, give food to the poor, and renew their prayers for the happiness of the dead person. Phil. Trans. N° 243.

MOUSE, *mus*, in *Zoology*. See MUS.

MOUSE, in the *Sea Language*, is a sort of knob, usually in the shape of a pear, wrought on the outside of a rope, by means of spun-yarn, parselling, &c. and used to confine some other securely to the former, and prevent it from sliding along its surface. These *mouses* are particularly used on the stays of the lower mast, to prevent the eye from slipping up to the mast.

MOUSE, *ear*. See HOUNDE.

MOUSE, *fossil*, called also *lemmer*, or *lemming*, in *Natural History*, the name of an animal found in Lapland, and in other cold countries: many extraordinary things are related of the manner of living of these creatures.

This is the MUS *lemmus* of Linnæus, with a short tail, five toes on the fore, very short legs, large whiskers, small eyes, long sharp teeth, and a yellow body varied with black. See NORWAY RAT.

They are of the bigness of a squirrel, and their skin is streaked with brown and black; there are also some spots beside the streaks; the black is a very fine deep colour, the brown is pale; they have two very sharp teeth above, and two below of the same kind; their feet are like a squirrel's; they are usually very fat and flothy, and are so quarrelsome and fierce, that if a stick be held out to them they will bite at it, and will hold it so fast, that they may be tossed and swung about in the air by it without letting it go. In their march they usually keep a direct line from north-east to south-west, and always travel in thousands in the same troop. The whole number forms a square body, and they march only from the time of the twilight to the morning, lying still all the day.

They march in lines, which are some ells distant, but always exactly parallel to each other, so that the places they have gone over look like the furrows of a ploughed field. If they meet with any thing in their way that might deter another animal, it never stops them; but though it be fire, a deep well, a pond, a torrent, or a bog, they without hesitation venture through, and by that means many thousands of them are destroyed, and are found dead in the mornings, in the waters or otherwise.

They never come into a house, nor meddle with any thing that we eat; if they chance to come to a house in their way, there they stop till they die; but if they come to a stack of hay or corn, they eat their way through.

When they march over a meadow, they do it great damage, by eating the roots of the grass; but if they encamp there, they wholly destroy the produce; the land looks like a place where there had been a fire, and the whole surface looks as if strewed with ashes.

The Laplanders are always glad to see these creatures on their march, for it always foretels plenty of more valuable creatures among them: the same cold that sends these out, sending also a number of fowl, squirrels, foxes, and other animals the same way. Wormius has written a complete treatise on this animal, calling it MUS *Norwegicus*: this is reprinted at large in his Museum.—Phil. Trans. N° 251. p. 112.

They commonly visit the country once or twice in twenty years: Linnæus supposes that they come from the Norwegian Lapland Alps; but Pontoppidan thinks that Kolan's rock, which divides Nordland from Sweden, is their native place. After ravaging the country, destroying the grass, and infecting the very ground, they at length perish, either through want of food, destroying one another, or in some great water or the sea.

MOUSE, *sea*. See APHRODITA.

MOUSE-*ear*, in *Botany*. See HAWKWEED.

MOUSE-*ear chickweed*, in *Botany*, *cerastium*, a genus of the *decandria pentagynia* class. Its characters are these: it has a permanent five-leaved empalement, which spreads open; the flower has five bifid petals, and ten slender stamina; in the centre is situated an oval germen, with five styles; the empalement afterward becomes an oval cylindrical or globular capsule, with one cell, containing many roundish seeds. Miller enumerates five and Linnæus fifteen species.

MOUSE-*ear scorpion-grass*, *myosotis*, in *Botany*, a genus of the *pentandria monogynia* class. Its characters are, that the corolla is hypocrateriform, marginated, and divided into five segments. There are four species.

MOUSE-*tail*, *myosurus*, in *Botany*, a genus of the *pentandria polygynia* class. Its characters are, that the five-leaved empalement is joined to the base; it has five awl-shaped peraliform nectaria, and many seeds. There is only one species.

This plant is very near akin to the ranunculus, under which genus it is ranged by some botanists; the flowers are extremely small, and are succeeded by long slender spikes of seed, resembling the tail of a mouse, whence it obtained its name: it grows wild upon moist ground in divers parts of England. The whole plant is used, and by some thought to possess the same virtues with plantain, and the coronopus.

MOUSING *a hook*, in *Sea Language*, the operation of fastening a small cord or line across the upper part from the point to the back thereof, in order to prevent it from unhooking, by the motion of the vessel, or otherwise.

MOUTH, in *Anatomy*, a part of the human face, consisting of the lips, the gums, the inside of the cheeks, and the palate.

All these parts are lined with a glandulous coat, which is continued over the whole inner surface of the *mouth*, and all its parts, the teeth excepted.

From the glands of this coat, through innumerable little excretory ducts, is separated a kind of lifeless juice, which serves to keep the *mouth* and all its parts moist, smooth, and slippery.

On the hind part of the palate, perpendicularly over the rima of the larynx, hangs a round, soft, smooth body, like the end of a child's finger, formed by the duplicature of the

the membrane of the palate, and called the *uvula*, which is moved by two muscles, called *sphenostaphylinus* and *pterygostaphylinus*; and is suspended by as many ligaments.

Under the membrane of the palate are a great number of glands, pretty conspicuous in the fore-part, like grains of millet; whose excretory ducts, piercing the membrane, open into the *mouth*: but towards the hinder-part they lie much thicker, and about the root of the uvula they are gathered so close to one another, that they seem to form one large conglomerate gland; which is therefore, by Verheyen, called *glandula conglomerata palatina*. See PALATE. The gums are, as it were, the lockets and ligaments of the teeth.

Besides the proper parts of the *mouth*, there are in and about it others highly serviceable and necessary thereto; among which are the glands; the most considerable whereof are, the parotides, the glandulæ maxillares, the sublinguales, and the tonsils, or amygdalæ; which see in their respective places.

These are the salival organs, whence springs all that liquor we call the *spittle*, which flows into the *mouth* by the respective ducts, after its separation from the blood in the bodies of the glands: as the demand of spittle is greater in actions of the lower jaw, i. e. in mastication, deglutition, much talking, &c. so does the supposition of these salival ducts favour that discharge on those occasions.

Whether the *mouth* of a fœtus be necessary for its nutrition, has been controverted. The learned Mr. Monro is of opinion it is not: see his reasons, and the answers to what has been advanced by many learned men in favour of the contrary opinion, in the Med. Ess. Edin. vol. ii. art. 9. or the Abridgment, vol i. p. 305.

Mr. Monro observes farther, that the opening of the *mouth* does not only depend on the motion of the lower jaw downwards, but also on the superior jaw being raised up by the muscles, which extend the head back. He says any one may convince himself of the truth of this, by putting the blade of a knife opposite to the conjoined edges of the teeth, when the *mouth* is shut; and the knife being held unmoved while the *mouth* is opened, he may, by the help of a mirror, see the upper-teeth raised remarkably at every aperture he performs. Med. Ess. Edin. vol. i. art. 1.

Dr. Derham observes, that the *mouth*, in the several species of animals, is nicely adapted to the uses of such a part; and well sized and shaped for the catching of prey, for the gathering and receiving food, the formation of speech, &c.

In some creatures it is wide and large, in others little and narrow; in some it is formed with a deep incisure up into the head, for the better catching and holding of prey, and more easy comminution of hard, large, and troublesome food; in others with a shorter incisure, for the gathering and holding of herbaceous food.

In the fish-kinds the *mouth* is very different in the several genera and species in its situation, figure, and proportion, and is by the best naturalists made a mark of distinction among them. In regard to situation, it is, 1. in some placed in the front or tip of the head; and in this case both jaws are sometimes of the same length; but sometimes the one is considerably longer than the other. 2. In some the *mouth* is placed in the lower or under part of the head, under the snout. 3. In some it is placed transversely in the body; i. e. the opening of the *mouth* cuts the line of the back and belly at right angles. 4. In others it is oblique. As to figure, there are also many differences. When the *mouth* is opened; in some, it is, 1. of an oblong, round, or roundish square shape. 2. In others it is oblong and wide. 3. It is also spherical. The proportion of the *mouth* to the head is also various. 1. In some it is much smaller than the breadth of the head; and, 2. in some it is equal, or nearly equal to the width of the head. Artedi.

In insects it is very variable: in some it is forcipated, to catch, hold, and tear the prey; in others aculeated, to pierce and wound an enemy, and suck their blood; in others strongly tufted with jaws and teeth, to gnaw and scrape out their food, carry burdens, perforate the earth, nay, and the hardest wood, and even stones themselves, for holes and cells for their young.

Nor is the *mouth* less remarkable in birds, being neatly shaped for piercing the air, hard and horny, to supply the want of teeth; hooked, in the rapacious kind, to catch and hold their prey; long and slender, in those who have their food to grope for in moorish places; and broad and long, in those that search it in muddy places.

MOUTH is also used, in the courts of princes, for what relates to their eating and drinking. Hence, *officers of the mouth, groom of the mouth*, &c.

Du-fer defines *mouth*, an apartment composed of several rooms, as offices, kitchens, &c. where the meat intended for the first tables is dressed by itself. At court, this is called the *king's mouth*.

MOUTH, in the *Manage*, denotes a horse's feeling or sensibility in that part where the bits are applied. See HORSE.

MOUTH, *shape of a bit's*. See BITS.

MOUTH, *opening*, in *Roman rite*, of a cardinal, is a ceremony used in the consistory at Rome; wherein the pope shuts a new-elected cardinal's *mouth*, to that he may not speak at all, even though the pope should speak to him; and remains, in the mean time, deprived of all voice, both active and passive, till the calling of another consistory, when the pope *opens his mouth* again, making a little harangue, to teach him how to speak, and comport himself in the consistory.

MOUTON *d'or*, an old French coin. See AGNEL.

MOXA, a sort of cotton, or downy substance, brought from China, and by authors said to grow on the lower part of the mugwort-leaf.

It is not much known among us for any medicinal efficacy: however celebrated in the Indies for curing the gout, by being burnt upon the part, people here have not faith enough to try it this way: and some think, if they had, in all likelihood, any other caustic would do as well.

The ancient physicians used flax, as the people of the eastern nations now do their *moxa*, for cauterizing in certain parts of the body. The method of using the *moxa* is this: a small cone of the down, or *moxa*, is to be made up of about a thumb's breadth long, much after the manner they are for a fusitus. The bulk of this cone is to be stuck upon the part with a mucilage of gum arabic, and its top is then to be set on fire by a candle of burning coal; by this means the whole cone will be gradually consumed, and the part by degrees cauterized. This is used in cases of the GOUT; and if the pain does not cease on the first operation, it is to be repeated till it does. Heister's Surgery, p. 349.

MOYNOU, in *Fortification*. See MOULEAU.

MUCILAGE, *mucilago*, in *Pharmacy, &c.* a thick viscous juice, of a white transparent colour; so called as resembling the MUCUS of the nose.

Mucilages are prepared chiefly from roots and seeds, pounded in a mortar, and infused in hot water, and strained through a cloth: and they are the most relaxing, emollient, and softening remedies in medicine.

The roots principally used for this purpose are those of althæa, mallows, symphytum, &c. the seeds are those of quinces, flea-wort, &c.

Mucilages enter the composition of several plasters. They are sometimes also made of gums and fruits; as figs, quinces, juniglans, tragacanth, &c.

MUCILAGE also denotes a thick pituitous matter, evacuated with the urine, in the gravel and dysuria.

MUCILAGINOUS *glands*, a very numerous set of glands in the joints, first described by Dr. Havers.

There are two sorts of *mucilaginous* glands, some small, next a-kin to miliary glands, being glandules placed all along the surface of the membranes which lie over the articulations. See MUCUS, and ARTICULATION.

The other sort are conglomerated, or are many glandules collected, and planted one upon another, so as to make a bulk, and appear conspicuously. In some of the joints there are several of them; in others there is a single one.

As to the structure of these large glands, they consist of small vesicles, which are not gathered together into several lobes, or bags of glandules, but are disposed upon several membranes lying over one another; of which membranes there are several in every one of these glands, which appear evidently in those who are hydropical.—They have their blood-vessels, as other glands; but their veins have a particular texture, in their course, for retarding the return of the blood from the glands, that the *mucilaginous* liquor, which is not separated with the greatest expedition, may have time for separation; which is a contrivance observed wherever a thick fluid is to be secerned.

The large *mucilaginous* glands are variously situated; some in a sinus formed in the joint; others stand near or over against the interstice between the articulated bones: but in general they are so placed, as to be squeezed gently, and lightly pressed, in the inflexion or extension of the joint, in order to yield a quantity of mucilage proportionate to the motion of the part, and the present occasion, without any injury.

The design of all these glands is to separate a *mucilaginous* kind of liquor, which serves principally to lubricate the joints, or to make them slippery; it serves likewise to preserve the ends of the articulated bones from attrition and beating: but all this it does in conjunction

with the medullary oil; with which, together, is made a composition admirably well fitted for those ends; for the mucilage adds to the lubricity of the oil, and the oil preserves the mucilage from growing too thick and viscous. Dr. Havers observes the same glands to lie between the muscles and tendons; and supposes that there is the same mixture there of an oily and *mucilaginous* substance; the one being that fat, which is found between the muscles, and is supplied by the glandulæ adiposæ; and the other separated by the *mucilaginous* glandules, of which the common membrane of the muscles is every where full. This mixture in the interstices of the muscles lubricates them, and their tendons; and preserves them from shrinking, and growing rigid and dry.

The rough uneven depression at the bottom of the cotyloide cavity of the ossa innominata is filled by a broad, flat, *mucilaginous* gland, bordered with a fatty substance, and covered with a fine membrane. The *mucilaginous* glands of the bones of the leg lie in small spaces, depressions, and superficial notches, near the edges of the cartilages of each joint, and are all covered by the capsular ligaments. In the bones of the foot these glands answer in number and figure to the depressions between the *cartilaginous* edges and ligaments.

In the articulations of the sternum, vertebræ, and ribs, the *mucilaginous* glands are very small; but they are accompanied by many fatty molecules lying round each joint. The inner surface of the ligamentary tube which lines the bone canal of the spine, is lubricated also by an oily or adipose substance. And the true *mucilaginous* glands of the occipital and maxillary articulations in the bones of the *head*, are all proportioned to the joints to which they belong, and lie between the capsular ligaments and the circumferences of the cartilages. Winslow.

MUCILAGO, in *Botany*, a name under which Micheli has comprised some species of that kind of fungus called MUCOR, consisting of small bladders, or vesicles, with seeds affixed to filaments on the inner part.

MUCK. See Mock.

MUCOCARNEOUS, an epithet used by authors for a sort of abscesses, which are partly made up of flesh, and partly of a thick mucous matter.

MUCOR, in *Botany*, a name given by Micheli, and continued by Linnæus, to a genus of mushrooms, often comprised by authors among the moffes, and called by the same Micheli, under the small varieties of some of the species, *muscilago* and *farago*. Their characters are these: they are fungules consisting of roundish little bladders, in which are found numerous seeds affixed to fibre-like receptacles, placed all over the inside of the bladders. Linnæus enumerates twelve species.

MUCOSA, in *Ichthyology*, a name given by the Italians to a species of the raya, called by the old authors, *lisirata*, and *lia marjana*; and, by the later authors, *raya expynchus* and *lavernia*. It is distinguished by Arteds by the name of the variegated ray, with ten prickly tubercles on the middle of the back. See Raia.

MUCOUS *fevers*, a term used by medical writers to express those fevers in which nature is endeavouring to rid herself of an abundance of pituitous, mucous, and serous matter. The catarrhal fevers of all sorts are expressed under this denomination. See Fever.

MUCOUS *glands* are three glands which empty themselves into the urethra; so called by the first discoverer, Mr. Cowper, from the tenacity of the liquor which they separate. See *Phil. Trans. Abridged*, *vol. ii. p.* 8, &c.

The two first discovered of these are about the bignefs of a French bean, of a depreffed oval figure, and a yellowish colour, like the proftates; being on each fide the bulb of the cavernous body of the urethra, a little above it.

Their excretory ducts fpring from the internal furface, near the inner membrane of the urethra; into which they open a little lower, by two diftinct orifices, juft below its bending under the offa pubis, in perinæo, where they difcharge a tranfparent vifcous liquor.

The third *mucous* gland is a fmall, conglobate, yellowifh gland, like the former, but fomewhat leſs, ſituate above the angle of bending of the urethra, under the offa pubis, in the perinæum, near the anus. It has two excretory ducts, which enter the urethra obliquely, a quarter of an inch below the two former; and difcharge a liquor like the former, both in colour and conſiſtence.

MUCRO *cordis*, in *Anatomy*, the lower or pointed end of the heart.

The word is Latin, *mucro*, where it properly ſignifies *the point of a ſpear*.

Hence, MUCRONATED is applied to whatever tends to, or terminates in a point, like that of a ſpear; as *mucronata cartilago*, &c.

MUCU, in *Ichthyology*, the name of a Brafilian fiſh of the lamprey kind. It is long and ſlender; its head is pointed; its eyes black and ſmall; and its mouth very ſmall; and it has no fins; it is brown all over, only of a duſkier colour on the back than on the belly, and has a number of obliquely tranſverſe lines on the ſides, which are black. It is an eatable fiſh, and is caught in lakes in Brafil.—Margrave.

MUCUNA *grows*, the largeſt and moſt beautiful ſpecies of phaſeolus growing in Brafil; it grows on a tree of the ſame name: the pod has a black ſhell, almoſt as hard as a ſtone, and covered with ſoft yellow hair, is a hand's breadth long and three fingers breadth wide. When broke open, it diſcovers three or four very beautiful globular beans, divided by interſtices of a ſcarlet or red colour, round, ſmooth, and with a large eye, which, being macerated in water, are deprived of ſome part of their noxious qualities; and being prepared with *ſpices & medicines*, are eaten by the natives; ſo that their poiſonous quality does not ſeem ſo deeply implanted in them by nature, as not to admit of proper correctives; for though the interior ſubſtance of the bean, by its acrimony and biting property reſembling the ſiſcera, excites great perturbations in the body, and purges violently by ſtool and vomiting, the cooling and demulcent medicinal aliment, prepared of the ſpices, ſerves as an antidote, and is therefore preferable to other things employed to correct it. Ray.

MUCUS *of the joints* is a mucilaginous liquor, ſeparated by its proper glands, conveniently placed in the interſtices of the bones, where thoſe glands are gently preſſed by the motion of the parts: it ſerves to make the extremities of the bones or joints ſlip more eaſily.

MUCUS *of the urethra*, a viſcous tranſparent liquor, ſerving to line and lubricate the parts that the ſeed and the urine may ſlip more freely, without either adhering to or lacerating the part.

It comes from glands, lately diſcovered by Mr. Cowper, about the penis; and is that, which in women is often miſtaken for ſemen.

MUCUS *of the noſtrils* is a viſcid excrementitious humour ſeparated by its proper glands, placed in the internal membrane of thoſe parts. It ſerves to moiſten, lubricate, and defend the olfactory nerves; which, being extremely ſoft and naked, would, without ſuch proviſion, be ſoon ſpoiled. See Nose.

MUCUS *of fiſh*. The bodies of moſt of the fiſhes called *ſcaly-ones* by authors, from their having either no ſcales at all, or only a few ſmall ones, are covered in the place of ſcales with this *mucus*. It is a tough and thick viſcous liquor, and ſticks firmly to the body, defending the ſkin from injuries from ſtones, and the like: it is ſecreted from certain glands placed about the head, and on moſt parts of the body, but particularly in the lines lateralis. Artedi.

MUD *walls*. See Wall.

MUDD, in *Ichthyology*, a name given by the Swedes to the fiſh called by Schoneveldt and others *aphya* or *aphye*.

It is a ſpecies of the CYPRINUS, according to Artedi, and is diſtinguiſhed by that author by the name of the *ſides and two-inch cyprinus*, with nine bones in the pinna ani.

MUEZDEM, among the Turks, an officer belonging to their moſques, who with his voice calls the people to prayers; thereby ſupplying the want of bells, which the Mahometans will not uſe. See Bell and Mosque.

MUFFLE, in *Metallurgy*, is an arched cover, reſiſting the ſtrongeſt fire, and made to be placed over coppels and teſts in the operations of allaying, to preſerve them from the falling of coals or aſhes into them; though at the ſame time of ſuch a form, as not to hinder the action of the air and fire on the metal, nor prevent the inſpection of the allayer.

The *muffle* may be made of any form, ſo that they have theſe conditions; but thoſe uſed with coppels are commonly made ſemi-cylindrical, or when greater veſſels are employed, in form of a hollow hemiſphere.

The *muffle* muſt have apertures, that the allayer may look in, and the fore part of it muſt be always quite open, that the air may act better in conjunction with the fire, and be inceſſantly renewed; for without this, ſcarce any fumes are to be produced, and without theſe, the vitrification of lead is ſcarce practicable; for when the air is once filled with a certain quantity of vapours, it ſcarce admits any more afterwards; and for this reaſon a conſtant ſucceſſion of freſh air is neceſſary. The apertures in the *muffle* ſerve alſo for the regimen of the fire; for the cold air ruſhing into the larger opening before, cools the bodies in the veſſel; but if ſome coals are put in it, and its aperture before be then ſhut with a door fitted to it, the fire will be increaſed to the higheſt degree; much more quickly than it can be by the breathing-holes of the furnace. Another uſe of theſe apertures is alſo, that the arſenical vapours of lead and antimony,

paſſing

passing through the holes in the back part of the *muffle*, may not be offenſive to the aſſayer, who ſtands before it.

As to the height, length, and depth of the *muffle*, theſe muſt be proportioned to the ſize and number of the veſſels they are intended to cover; and care muſt be taken in theſe, that all parts of the inner furface of their veſſels muſt be in the reach of the aſſayer's eye. The moſt frequent ſize of the *muffle*, has been, in four inches height, or eight inches long, and four or ſix inches broad. The ſegments cut out at the ſides, for the leſſer holes, muſt be of ſuch a proportioned height, that the leaſt veſſels put under it may not be in the way of coals or aſhes falling into them, for that always hinders the aſſay-maſter of leaſt, and the moſt accuſtomed of other metals and ſemi-metals, and will ſometimes entirely reduce them again when already deflagrated; and the ſcoriæ, ſoftened by aſhes, joſtle and corrode the cupellæ.

Wooden moulds of proper ſhape, are moſt convenient for the making theſe *muffles* in, and the matter for making them of is the ſame with that of the German clay-veſſels; that is, either a pure native clay, or a compoſition to bear the fire, which will be known upon the trials or ſuch clay hardened by a mixture of the powder of ſtones; and in order to the forming of theſe, the maſs muſt be made tolerably ſoft and pliant. Knead a ſufficient quantity of this maſs with your hands upon a flat ſtone; ſpread it out exactly into a thin cake or plate, ſomewhat longer and broader than you intend the *muffle* to be made; and ſo thick, that two or more thin plates or lamina, of about two lines thick each, may be cut out from it. This is eaſily done by rolling the maſs on the ſtone with a rolling-pin, ſtrewed over lightly with aſhes, or powder of chalk.

When the cake is thus rolled out, with a thin, fine, and perfectly ſtraight braſs-wire cut off from the cake one thin plate; this muſt be done with great caution leſt it ſhould break; take this up, and rubbing it over with oil or fat, lay it over the mould; then cut out a ſemicircular piece from the maſs, of the ſame thickneſs with the former, and with this cover the back plane, or further end of the mould, joining the edges of this plate to thoſe of the former, cloſely and perfectly, by wetting them well with water.

Next cut off from the cake another thin plate, to be the bottom of the *muffle*; this may be either left looſe for the *muffle* to be pinned on it occaſionally, or the bottom edges of the already formed *muffle* may be joined to it all round by means of water, as the back was before joined to the arched part of the *muffle*. But whether it be intended that the bottom ſhall be thus fixed on, or left looſe, it muſt be half an inch broader every way than the bottom of the *muffle*, that this may ſtand the more ſafe and firm upon its baſis.

When the *muffle* is thus made, wet your hand, and rub it carefully all over, that the ſmall and perhaps inviſible cracks and chinks in the plates may be gladly joined, and the whole matter of it applied perfectly cloſe to the ſurface of the mould.

When the *muffle* has been ſome time expoſed to the air, and is tolerably dried, and hardened on the mould, cut out two or three hemiſpherical pieces on each ſide, to make the holes before deſcribed, at the bais and back; and then draw away the mould from within it, for if the *muffle* is ſuffered to dry perfectly on the mould, it always cracks. When the whole is perfectly dry, let it be baked in a potter's kiln, or in the aſſayer's own; but without great care in the latter method, and lighting the fire at top at firſt, it is apt to crack, ſo that the potter's kiln, where at hand, is much the better way of baking it. See *Table* II. *of Chemiſtry*, N° 151, 56.

If there be adapted to the formerly deſcribed convex mould, another concave one nearly fitting it, only leaving room for the thickneſs of the *muffle* between, and the clay be placed between them, and formed by this means into its exact ſhape, by a ſtrong and every way equal preſſure, this will make *muffles* not only with much leſs trouble, but they will be much ſtronger, leſs apt to crack, and more capable of reſiſting the fire, than thoſe made by the hand in the other way.

The only cautions neceſſary for making theſe, are, that the clay be a little drier than when it is to be worked by the hand; that the ſides, both of the inner or convex mould, and of the outer concave one, be thoroughly oiled or greaſed, and the preſſure on the ſurface of the outer or concave mould, be as ſtrong and equal as may be. There is no clay better for making theſe *muffles* than the *Wenſor-loam*, an earth well known among the chemiſts and platiners, and always to be ſold in London; and rubbing the inſide of the mould with black lead in fine powder very well ſupplies the place of greaſing them, to prevent the matter from ſticking to them.

Theſe are the *muffles* ordinarily uſed in aſſaying; but when very large teſts are to be covered, they uſe large ſemicircular *muffles*, made of caſt iron, or ſometimes of the ſame clay, and wrought in the ſame manner, only made upon proportionably larger moulds. The clay is uſually, for theſe large ones, only laid in a lump on the top of the mould, and with wet hands ſpread all over it to the bottom, and by this means a *muffle* is made with little trouble. Cramer.

MUFFI. See MUFFLE.

MUGGENT, in *Zoology*, the name of a ſpecies of freſh water wild duck, called by many authors the *merganſer*, from its catching fiſh that play on the ſurface of the waters.

It is about the ſize of the common tame duck; the beak is ſhort and broad, and is of a ſaffron colour; it is all over of a mottled colour, like that of the partridge, made up of black, white, brown and grey, ſo oddly mixed together, as to ſhew neither ſeparately: the crown of the head is black, and the feet are yellow.

Mr. Ray ſuſpects this not to be different from our common wild duck.

MUGGLETONIANS, a religious ſect, which aroſe in England about the year 1657, ſo denominated from their leader, Ludowick Muggleton, a journeyman taylor.

Muggleton, with his aſſociate Reeves, ſet up for great prophets; and, it is ſaid, pretended to an abſolute power of ſaving and damning whom they pleaſed; giving out, that they were the two laſt witneſſes of God, that ſhould appear before the end of the world.

MUGIL, in *Ichthyology*. See MULLET.

MUGWEED, in *Botany*. See CARDUUS.

MUGWORT, *artemiſia*, in *Botany*, a genus of the *polygamia ſuperflua* claſs. Its characters are theſe: the flower is compoſed of hermaphrodite and female florets; the hermaphrodite flowers compoſe the diſk or middle, in the centre is placed the germen, which is encompaſſed by five hairy ſtamina; the germen becomes a ſingle naked ſeed, ſitting upon a naked placenta. Linnæus enumerates twenty-two ſpecies, joining to this genus the *abrotanum* and *ſantolina*; but Miller only reckons two ſpecies; of which the common ſort grows naturally on banks and the ſides of footpaths, in moſt parts of England.

The *mora*, ſo famous in the cathartic countries, for curing the gout, by burning the part affected, is the bunch or down which is on the under part of the leaves of *ſempervivum*. *Mugwort* has long been famous as an uterine and antiſpaſmodic, and a medicine of great efficacy in all diſeaſes of the nerves. It is ſuddenly operative and abſtergent; it promotes the menſes, and cleanſes the womb. It is given in decoction, or much more agreeably in a light infuſion, in the manner of tea. The midwives uſe it alſo externally, boiling it, and applying it to the belly, to promote the menſtrual diſcharges, or the expulſion of the ſecundines. It is by ſome much recommended as a cure for the *ſcurvy*, and is to be taken for this purpoſe, either in powder, two drams for a dole, or the expreſſed juice, drank an ounce or two twice a day for ſome months. There uſed to be a diſtilled water, a ſyrup, a conſerve, and an extract of *mugwort* in the ſhops, and the laſt was made as that of wormwood; but at preſent theſe are diſuſed, and the dried herb only is kept there, as an ingredient in ſome of the compound waters.

MUID, a large meaſure, in uſe among the French, for dry commodities; as corn, pulſe, ſalt, lime, coals, &c.

The *muid* is no real ſettled uſed as a meaſure; but an eſtimation of ſeveral other meaſures, as the ſeptier, mine, minot, buſſel, &c.

At Paris, the *muid* of wheat, pulſe, and the like, is compoſed of twelve ſeptiers, each ſeptier making two mines, the mine two minots, the minot three buſhels, the buſhel four quarts, or ſixteen litrons, each litron 96 cubic inches, exceeding our pint by 1½ cubic inch. The *muid* of oats is double that of wheat, though compoſed, like that, of twelve ſeptiers; but each ſeptier contains twenty-four buſhels. The *muid* of charcoal contains twenty mines, facks, or loads, each mine two minots, each minot eight buſhels, and each buſhel four quarts, &c.

Muid is alſo one of the nine caſks, or regular veſſels uſed in France, to put wine and other liquors in. The *muid* of wine divided into two *demi-muids*, four *quarts-muids*, and eight *half quarts-muids*, contains thirty-ſix ſeptiers, each ſeptier eight pints, Paris meaſure; ſo that the *muid* contains two hundred and eighty-eight pints.

MULÆ, a word uſed by ſome medical writers to expreſs puſtules on the ſkin, which are owing to extreme heat, or to cold.

MULA *herba*, in *Botany*, a name uſed by ſome for the cetrach, or ſmooth ſpleenwort.

MULATTO, a name given, in the Indies, to thoſe who are begotten by a Negro man on an Indian woman; or an Indian man on a Negro woman.

The

The word is originally Spanish, *mulato*, formed of *mulo*, a *mule*, as being begotten of two different species.

Those begotten of a Spanish woman and an Indian man, are called *mesti*; and those begotten of a negro by a *mesti* are called *jambos*. These are all very different in colour, and in their hair.

MULBERRY-*tree*, *morus*, in *Botany*, a genus of the *monœcia tetrandria* class. Its characters are these: it hath male flowers growing at separate distances from the female on the same tree: the male flowers are collected in long taper ropes of katkins; these have no petals, but have four long, awl-shaped, erect stamina: the female flowers are collected into roundish heads; these have no petals, but a heart-shaped germen, supporting two long, rough, reflexed styles, crowned by single stigmas; the empalement of these afterwards becomes large, fleshy, fuculent fruit, composed of several protuberances, in each of which is lodged one oval seed. Linnæus enumerates seven, and Miller eight species.

The common *mulberry*-tree, which grows naturally in Persia, from whence it was first brought to the southern parts of Europe, is to be propagated either by cuttings, or by laying down the tender branches, which in one year will be well rooted, and may be cut off from the tree, and transplanted into the places where they are to remain. But the better way is to propagate them by cuttings, which, if rightly chosen, and skilfully managed, will take root very well: these cuttings should be the shoots of the former year, with one joint of the two year's wood to the bottom; and they should be planted their whole length, leaving two or three buds above ground. The best season for planting them is in March, after the danger of hard frost is over: they should be planted in light rich earth, pressing the ground pretty close about them; and if they are covered with glasses, it will forward their putting out roots: but in the want of glasses, the ground about them should be covered with moss, which will render less watering needful. They may be transplanted the following spring into a nursery, where they should be trained to stems, by tying down stakes by each, to which the principal shoots should be fastened; and most of the lateral branches should be closely pruned off, leaving only two or three of the weakest to detain the sap, for the augmentation of the stem. After about four years growth in the nursery, they will be fit to transplant where they are to remain.

The *mulberry*-tree thrives best in a light soil, which should not be too wet, nor over dry; and if should always have an open exposure; for if planted too near the trees or buildings, to as to be shaded thereby, fruit seldom ripens well; though it will be to great advantage to have them defended from the west and south-west winds, by trees or buildings at a distance.

The soil under the *mulberry*-tree should always be well dug up every year, and manured, which proves of very great service to the fruit.

The white *mulberry* is cultivated in France and Italy for the sake of its leaves, as there is an opinion, that the silk-worms should be fed only with these; but it is affirmed by persons who seem to know best, that the Persians feed their worms only with the leaves of the black kind.

The trees intended for feeding silk-worms should not be suffered to grow tall, but kept in a sort of hedge; and instead of pulling off the leaves singly, they should be cut off with sheers together with the young branches; this is not only much sooner and more easily done, but it is less injurious to the trees. The white sort is propagated either by seeds or layers as the black, and is equally hardy. Miller.

The fruit of this tree, while unripe, is very astringent; but when thoroughly ripe, it is of a contrary quality, rather purgative, cooling, very pleasant, and quenching thirst. Its syrup, which is very pleasant, is the only use made of it in the shops.

The more general cultivating *mulberry*-trees in England might be of greater use than is at present supposed in many respects. In Devonshire they have a way of mixing *mulberry* juice with their cyder in the making, and this makes the very best of all English vinous liquors. And as to the great article of breeding silk-worms, though a recommendation from the crown could not bring about the planting these trees in sufficient number for it in James the First's time, yet the trees have been found to flourish every where with us when properly planted, and the worms feed very kindly and work very well with us. When this manufacture was first attempted, the people of many parts of England, nay, and in some parts of the dampest places in it too, tried it, and always with success. The only thing that stopped the progress of so valuable a thing at that time, was the want of a sufficient quantity of *mulberry*-trees, and the scheme has been neglected ever since. Phil. Trans. N° 133.

The tree was always esteemed by the ancients for its delicious fruit, before the use of its leaves was ever found out. The Romans, in the height of their luxury, preferred it before all the foreign fruits; and Columella and the other ancients are very explicit in the methods of propagating it.

The RUSTICK *mul*, which grows plentifully at Campeachy, and exported from Jamaica, is a species of the *mulberry*; as is also the China and Japan *mulberry*-tree, of the bark of which the inhabitants make paper.

MULBERRY-*tree*. See *Strawberry* BUSH.

MULBERRY-*wine*, a name given by the people of Devonshire, and some other parts of England, to a sort of cyder rendered exceptionable by an admixture of *mulberry* juice in the making: they choose for this purpose the ripest and blackest *mulberries*, and pressing out their juice and mixing it with a full-bodied cyder at the time of the grinding and pressing, give half so much of it as adds a perceptible flavour. It is very worthy the attention of people who live in other countries, where strong and good cyder is made, that this renders it a sort of wine much more agreeable than any other English liquor, and might be brought into general use, to the great advantage of the dealer. The colour of this liquor resembles that of the brightest red wine; and the flavour of the *mulberry* never goes off. Phil. Trans. N° 133.

MULBERRY-*shell*, a species of DOLIUM.

MULCH, a term used by gardeners for rotten dung, or the like, thrown upon beds of young plants, to preserve them from the bad effects of cold or drought.

MULCT, MULCTA, a penalty, or fine of money, imposed for a fault or misdemeanour.

MULE, *equus mulus*, in *Natural History*, a mongrel kind of quadruped usually generated between an ass and a mare; sometimes also between a horse and a she-ass: those of the first kind are reckoned the best.

Mules are a sort of monsters; and, therefore, they do not propagate their kind.

And yet the ancients mention a sort of *mules* that were prolific, in Phrygia, Syria, Cappadocia, and Africa. Witness Aristole, Hist. Animal. lib. vi. cap. 36. Varro de Re Rustica, lib. ii. cap. 1. Columella, lib. vii. cap. 36. Theophrastus, and, after him, Pliny, lib. viii. cap. 44.

Steno, examining the testicles of a *mule*, found ova therein, with a sort of placenta about them; which persuaded him, that *mules* might ingender without any miracle. But the observation is fanciful, and the conclusion unworthy so able a naturalist.

The Roman ladies had equipages drawn by *mules*; as appears from the medals of Julia and Agrippina. And, at this day, in Spain, the coaches of the nobility, and even of princes, are usually drawn by no other than *mules*.

We are assured, that M. de Thou, first president of the parliament, had the fourth coach in France, in 1585, till which time every body rode to court, parliament, &c. on *mules*.

These animals are very hardy. Savoy produces very large ones, but the finest are bred in Spain.

Mules are chiefly used in countries where there are rocky and stony ways, as about the Alps and Pyrenees, &c. Great numbers of them are kept in those places; they are usually strong, and are strong, well-limbed, and large, being chiefly bred out of fine Spanish mares.

The *mules* are sometimes fifteen or sixteen hands high, and the best of them are worth forty or fifty pounds a piece. No creatures are so proper for large burdens, and none so sure-footed. They are much stronger for draught than our horses, and are often as thick set as our dray horses, and will travel several months together, with six or eight hundred weight upon their backs. It is a wonder that these creatures are not more propagated in England, as they are so much hardier and stronger than horses, and are less subject to diseases, and will live and work to twice the age of a horse.

Those that are bred in cold countries are more hardy and fit for labour than those bred in hot; and those which are light made are fitter for riding than horses, as to the walk and trot; but they are apt to gallop rough, though these do it much less than the short-made ones.

They take so much after the mare they are bred from, that they may be procured of any kind, light, or strong, as the owner pleases. The general complaint we make against them, is, that they kick, and are stubborn: but this is only owing to our neglect in the breeding them; for they are as gentle as our horses in countries where they are bred with more care.

Mules generated between the horse and the she-ass, are the least valuable. They are commonly very dull, and take after the ass, and are not large; the other breed between an ass and a mare is therefore what is propagated chiefly in all countries where *mules* are used.

The

he-ass must be procured for this breed; and in Spain, where *mules* are greatly esteemed, they will give fifty or sixty pounds for a fine he-ass, only to be kept as a stallion. They breed with this creature out of the finest and largest mares they have, giving the ass an advantage of height of ground, and putting the mare into a narrow pit raised on each side.

The *mule* seems to be the only animal which the confusion of species has rendered barren; and if so, there must necessarily be something particular in those animals that have engendered it, which is not found in others; and that it, perhaps as Aristotle thinks, the hardness of the matrix in mares and asses, which, like an earth, is rendered sterile by dryness; whereas that reason has no place in leopards, foxes, and the like, which animals are fruitful enough to transmit to their posterity the strong dispositions they have for generation, notwithstanding the resistance which the mixture of the species may bring with it.

If the ass destined to be bred on is suckled by a mare, or the mare suckled with an ass, it makes them much more familiar than they would otherwise be; and this may always be done, by taking away the colt that belongs to the dam, and putting the other in its place, keeping them in the dark ten days or a fortnight.

MULLE, among *barbers*. See SCRATCHEL.

MULLEIN, *Fairchild's*, in *Botany*. See DIANTHUS and MULLI, below.

MULLI's *fern*. See HEMIONITIS.

MULLI, among *Gardeners*, denote a sort of vegetable monsters produced by putting the farina fecundans of one species of plant into the pistil, or utricle of another.

The carnation and sweet-william being somewhat alike in their parts, particularly their flowers; the *farina* of the one will impregnate the other; and the seed so enlivened will produce a plant differing from either. An instance of this we first had in Mr. Fairchild's garden at Hoxton; where a plant is seen neither sweet-william, nor carnation, but resembling both equally: this was raised from the seed of a carnation that had been impregnated by the farina of the sweet-william. These couplings being not unlike those of the mare with the ass, which produce the *mule*, the same name is given them; and they are, like the others, incapable of multiplying their species.

This gives us a hint for altering the property and taste of any fruit, by impregnating one tree with the *farina* of another of the same class; e. gr. a codlin with a pearmain, which will occasion the codlin to impregnated, to fall a longer time than usual, and to be of a sharper taste. Or if the winter-fruits be fecundated with the dust of the summer kinds, they will ripen before their usual time. And from this accidental coupling of the *farina* of one with another, it may possibly be, that in an orchard where there is variety of apples, even the fruit gathered from the same tree differ in their flavour, and in the season of maturity. It is also from the same accidental coupling that the numberless varieties of fruits and flowers raised every day from seed proceed.

MULGRANOC, an English name for a small sea-fish caught on the Cornish and other shores, the *almodi* vel *cephalus* of Rondeletius, the *blennius pholis*, of Linnæus, and the GALERITO of other authors.

MULIEBRIA, a term sometimes used to signify the privities of women; or so much as is otherwise called *cunnus*. See *Fin. Abnot. (Eglantine) fig.* 9.

MULIER, in *Law*, signifies lawful issue born in wedlock, but begot before.

If a man have a son by a woman before marriage, which is a bastard and illegitimate; and he after marries the mother of the bastard, while with child of another, and they have another son; this second son is called *mulier*, and is lawful, and shall be heir to his father. These are sometimes also find with the additions *postnatus legitimus*, and *mulier puisne*.

Some derive the word from the Latin *melior*, or French *meilleur*, *better*; in regard the condition of a son born thus is better than that of an elder brother born before wedlock. Though, according to Glanvil, the lawful issue is rather called *mulier* than *melior*, because begotten on *mulierem*, and not on *concubinam*; for he calls such issue *filios mulierosos*; opposing them to bastards. Agreeable to which, Britton has *fecere mulieri*, i. e. the brother begotten of the wife; in opposition to *fecere bastardi*.

The like seems to obtain in Scotland, where, according to Skene, *mulieratus filius* is a lawful son, begot of a lawful wife.

MULIER was also anciently used as an addition for a wife; sometimes also for a widow. According to Coke, virgin is also included under the name *mulier*.

MULIERTY, the being or condition of a *mulier*, or lawful issue. Co. Litt. 352.

MULLEIN, *verbascum*, in *Botany*, a genus of the *pentandria monogynia* class. Its characters are these: the flower has a small permanent empalement of one leaf, cut into five parts; it hath one wheel-shaped petal, with a very short cylindrical tube; the brim cut into five oval obtuse segments; and five awl-shaped stamina, which are shorter than the petal, terminated by summits, compressed; each summit with a roundish germen, supporting a slender style inclining to the stamina; crowned by a thick, obtuse stigma; the germen afterwards becomes a roundish capsule with two cells, opening at the top, having an half oval receptacle fixed to the partition, filled with angular seeds. There are thirteen species; the common sort used in medicine, grows naturally on banks and highways. *Mullein* is accounted pectoral, being good for coughs, spitting of blood, and other affections of the breast: it is likewise good for griping and colic pains, arising from sharp humours. Outwardly used in fomentations and fumigations, it is reckoned a specific against pains and swellings of the haemorrhoids, or piles.

The leaves of *mullein*, Lyt Dr. Lewis, recommended as mild astringents, have a roughish drying kind of taste, and very little smell: the flowers have also a like astringent sliuess, with a considerable sweetness.

MULLER, or MULLE, denotes a stone flat and even at bottom, but round atop; used for grinding of waters on a marble.

The apothecaries use *mullers* to prepare many of their suffaceous powders; and painters for their colours, either dry or in oil.

MULLER is an instrument used by the glass-grinders; being a piece of wood, to one end whereof is cemented the glass to be ground, whether convex, in a bason; or concave, in a sphere or bowl.

The *muller* is ordinarily about six inches long, turned round: the cement they use is composed of ashes and pitch. See GRINDING.

MULLER, in *Ichthyology*, a name used by some for the fish called in Latin the CATAPHRACTES, and in English the mailed fish, or pogge.

MULLET, in *Ornithology*, a name by which the peasants in some counties of England called the *avis aerius Logi*. See DUEL.

MULLET, in *Ichthyology*, a name given in England indeterminately to several kinds of fish, of different genera; but the proper sense of the word is the same with that of the *mugil* or cephalus, of the generality of authors; the *cephalus* of Aristotle and the Greeks; and the *cestreus* or cestreus of Oppian and others.

In the Artedian system of ichthyology, the characters of the *mugil* are these: the branchiostege membranes on each side contain six crooked bones; the upper one being the broadest, and being laid under the covering of the gills, so that only five are discernible; the scales are large, and they cover the head, and the opercula of the gills, as well as the body of the *fish*; the head is of a depressed figure in its anterior part; and the body is oblong and compressed. According to these distinctions, there is only one known species of *mugil*, that is the *mugil* of Ovid and the ancients. It resembles the thynnalus in its external figure. Its jaws are tender and thin, and have no teeth in them; the tail is forked.

In the Linnæan system, the *mugils* a genus of the *abdominales*; and he reckons two species, viz. the *cephalus* and *capito*.

Rondeletius, and other authors, have described three or four different species of *mugil*; but they form rather varieties of the same fish, owing to age, place, and other accidents.

This fish in some degree resembles the dog or dare in shape. The nose is long; the belly a little bowed; the head plain and flattish; its scales are very large, and cover not only the body, but the membranes of the gills, and a great part of the head; the back is of a dusky bluish or greenish brown; the belly white, and the sides are variegated with longitudinal black and white lines running from the head to the tail: its mouth is toothless, but the tongue is somewhat rough. It is supposed to feed wholly on weeds and the like; and seems indeed to eat no fish. It is most frequently caught at sea; but at times comes up into rivers.

The *mullet* is a very well tasted fish; and of its spawn is made what we call BOTARGO.

Mullets are found in great plenty on several of the sandy coasts of our island, and haunt in particular those small bays that have influxes of fresh waters. They come in great shoals, and keep rooting like hogs in the sand or mud, leaving their traces in form of large round holes. They are very cunning, and when surrounded with a net, the whole shoal frequently escapes by leaping over it; for when one takes the lead, the others are sure to follow. This fish was sometimes made the instrument of a horri-

ble punishment for unfortunate gallants; and was in use both at Athens and Rome. *Leribus Athenienſium adulteri in ipſo deprehenſi pœna fuit pactaudorum. Raphani lacu utebantur nonnunquam muriâ pisces, interdum ſcorpiones.* Cauſabon. Animadv. in Athenæum. lib. i. Juvenal Satyr x. v. 316. and Horace Satyr ii. lib. i. v. 132. refer to this punishment. Pennant.

MULLET, *black*, *mugil niger*, a name given by authors to a fiſh of the *mullet* kind, but all over black, more uſually known by the name of the *portius piſcis*.

MULLET, *winged*, *mugil alatus*, a name given by ſome authors to the *hirundo piſcis*, or ſwallow-fiſh, as, excepting its wing-fins, it very much reſembles the *mullet* in ſhape. See FLYING-*fiſh*.

MULLET, or MOLLET, in *Heraldry*, a bearing in form of a ſtar, or rather of the rowel of a ſpur, which it originally repreſented.

The *mullet* has but five points; when there are ſix it is called a *ſtar*. Though others make this difference, that the *mullet* is, or ought to be, always pierced, which a ſtar is not. *Tab.* II. *Heraldry, fig.* 73.

The *mullet* is uſually the difference, or diſtinguiſhing mark, for the fourth ſon, or third brother, or houſe.

Though it is often alſo borne alone, as coat armour: thus, Ruby on a chief pearl, two *mullets* diamond, was the coat of the famous Lord Verulam, firſt Sir Francis Bacon.

MULLUS, in *Ichthyology*, the name of a fiſh properly of the cuculus-kind, of which there are two ſpecies; the one called *mullus imberbis*, the other *mullus ſuper*. Linnæus makes the *mullus* a diſtinct genus of the thoracic fiſhes, the characters of which are, that the head is compreſſed, declining and covered with ſcales: the branchioſtege membrane contains three bones; and the body is covered with large ſcales, which eaſily fall off. He enumerates three ſpecies.

The *mullus imberbis* is a very ſcarce ſea-fiſh, with a large head, ornamented with ſeveral ſmall figures of ſtars, large eyes, a ſmall mouth of a fine bright red within, and without teeth; the covering of the gills has ſeveral prickles pointing towards the tail; the whole body is of a reddiſh colour, and the gill-fins have near their end ſome filamentous fingered appendages; its belly is white; and there are two rows of pointed bones running from the head to the tail all along the back.

The other, or *mullus ſuper*, is a ſmall fiſh about the length and thickneſs of a finger, and of a beautiful red or ſomewhat purpliſh colour; and is covered with ſcales ſerrated at their extremities, and placed obliquely. Rondelet. de Piſc. p. 640.

MULLUS *barbatus*, in *Ichthyology*, the name of a fiſh of the cuculus or the gurnard-kind, and in the Linnæan ſyſtem a ſpecies of the *mullus*, caught in the Mediterranean, and reckoned an extremely delicate fiſh for the table. Its uſual ſize is about ſix or ſeven inches in length; its head is flatted and its body conſiderably thick; and the back flat, not ridged; from the head all the way to the tail, it becomes gradually ſmaller, ſo as to reſemble an obeliſk in figure; its ſcales are ſerrated at the edges, and are eaſily rubbed off; they are of a brownith olive colour; but the ſides, when they are off, look as if tinged with red lead; the eyes ſtand very high in the head, and it has two very long beards under its chin; it has no teeth in the jaws, and its tail is very forked.

MULLUS *imberbis*, in *Ichthyology*, the name of a ſmall fiſh of the *mullus* kind, according to Linnæus, caught in the Mediterranean and Archipelago, and called by many *ſex mullarum* and *re de triglia*. Its uſual ſize is about four or five inches in length; it is all over of a reddiſh hue, and is covered with very large ſcales; its belly is alſo ſomewhat prominent, by which it is diſtinguiſhed from all the other mullets; its eyes are large, its mouth very wide, and its jaws rough like a file; its tail is forked, and it has no beards.

MULSUM, MULSE, a liquor made of wine and honey; or even of honey and water. See HYDROMEL.

MULTA, MULTURA, *epiſcopi*, a fine, or final ſatisfaction anciently given the king by the biſhops, that they might have power to make their laſt wills; and that they might have the probate of other men's, and the granting of adminiſtrations.

MULTANGULAR, a figure, or body, which has many angles.

MULTIBONA, in *Botany*, a name given by ſome authors to parſley.

MULTIFIDUS *ſpinæ*, in *Anatomy*, a name given by Albinus to a *muſcle*, the ſeveral parts of which he ſays have been called by ſeveral different names by the generality of anatomical writers.

That part of it which is ſituated in the region of the loins, is called by Veſalius, the *decimus tertius* and *decimus quartus deſum movantium*, and by ſome the *tertius deſti muſculus*.

That which is ſituated in the back is called by Veſalius, *decimus quintus* and *decimus ſextus deſum movantium*, and by others, *quintus deſti muſculus*.

That part which is in the neck is called by Veſalius, the *ſeptimus* and *octavus deſum movantium*, and by many the *quartus cervicis muſculus*; and by Fallopius, *pars tertii paris muſculorum deſti*. That part of it which is in the loins and back is called by Fallopius the *quartum par muſculorum deſti*, and ſeems to be the *facies* of Riolanus.

That part which is in the neck is called by Riolanus alſo a part of the ſpinatus, and by ſome the *tranſverſalis colli*: and its diſtinct portions in the neck are called by Douglas the *inter ſpinales*.

MULTILATERAL, in *Geometry*, is applied to thoſe figures which have more than four ſides or angles, more uſually called POLYGONS.

MULTINOMIAL, or MULTINOMIAL *roots*, in *Mathematics*, are ſuch as are compoſed of many names, parts, or members; as, $a+b+c+d$, &c.

For the method of raiſing an infinite *multinomial* to any given power, or of extracting any given root out of ſuch a power, ſee a method of M. de Moivre, in Phil. Tranſ. N° 230.

MULTIPLE, MULTIPLEX, in *Arithmetic*, a number which comprehends ſome other ſeveral times.

Thus 6 is a *multiple* of 2, or, which is the ſame, 2 is a quota part of 6; 2 being contained in 6 three times. And thus 12 is a *multiple* of 6, 4, 3, and comprehends the firſt twice, the ſecond thrice, the third four times, &c.

MULTIPLE *ratio*, or *proportion*, is that which is between *multiple* numbers.

If the leſſer term of a ratio be an aliquot part of the greater, the ratio of the greater to the leſs is called *multiple*; and that of the leſs to the greater *ſub-multiple*.

A *ſub-multiple* number is that contained in the *multiple*. Thus the numbers 1, 2, and 3, are *ſub-multiples* of 6 and 9.

Duple, triple, &c. ratios; as alſo ſub-duples, ſub-triples, &c. are ſo many ſpecies of *multiple*, and *ſub-multiple* ratios.

MULTIPLE *ſuperparticular proportion*, is when one number or quantity contains another more than once, and a certain aliquot part; as 3 to 1.

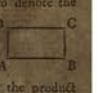
MULTIPLE *ſuperpartient proportion*, is when one number or quantity contains another's diverſe times, and ſome parts beſides; as 4 to 1.

MULTIPLE *echo*. See ECHO.

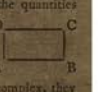
MULTIPLICAND, in *Arithmetic*, is one of the factors in the rule of multiplication being that number which is given to be multiplied by another called the *multiplicator*, or *multiplier*.

MULTIPLICATION, the act of *multiplying*, or increaſing the number of any thing.

Accurately ſpeaking, in every *multiplication*, the multiplicator muſt always be conſidered as a number; and it is eaſy to conceive a quantity of any kind multiplied by a number. But to talk of a pound multiplied by a pound, a debt by a debt, and a line by a line, &c. is unintelligible. However, by analogy, in the application of algebra to geometry, we meet with ſuch expreſſions, and nothing is more common than to find $AB \times BC$, to denote the rectangle ABCD, the length of which is AB, and the breadth BC. But this is only to be underſtood by analogy; becauſe, if the number expreſſing the meaſure of the ſide AB was multiplied by the number expreſſing the meaſure of BC, the product would expreſs the meaſure of ABCD.



The ſign of *multiplication* moſt commonly uſed among algebraiſts, is $\times$. But the Germans, after Leibnitz, only make uſe of a point placed between the quantities multiplying each other, thus; $a \cdot b$ is the ſame as $a \times b$ and $AB \cdot BC$, the ſame as $AB \times BC$, or the rectangle of AB into BC, that is the rectangle ABCD.



When the quantities to be multiplied are complex, they place them between a parenthеſis, inſtead of drawing a line over them, as we commonly do.

Thus they write $(a+b) \cdot (c+d)$ inſtead of $\overline{a+b} \times \overline{c+d}$, for the product of $a+b$ into $c+d$. Sometimes the point is omitted, thus: $(a+b)\ (c+d) = a+b \times c+d$.

An old ſtatute ſays, it is ordained and eſtabliſhed, that none from henceforth ſhall uſe to *multiply* gold, or ſilver, nor uſe the craft of *multiplication*; and if any the ſame do, he ſhall incur the pain of felony. Stat. 5 Hen. IV. cap. 4.

This ſtatute was made on preſumption that ſome perſons, ſkilful in chemiſtry, could *multiply* or augment thoſe metals by elixirs, or other ingredients; and change other metals into very gold and ſilver. Under Henry VI. letters patent were granted to certain perſons (who undertook to perform the ſame, and to find the philoſopher's ſtone),

ſtone), to free them from the penalty in the ſaid ſtatute. But the ſtatute has been ſince repealed. 1 Will. and Mar. cap. 30.

MULTIPLICATION, in *Arithmetic*, the act, or art of *multiplying* one number by another, to find the product.

Multiplication, which is the third rule in arithmetic, conſiſts of finding ſome third number, out of two others given; wherein one of the given numbers is contained as often as unity is contained in the other.

Or, *multiplication* is the finding what will be the ſum of any number added to itſelf, or repeated, as often as there are units in another. So that the *multiplication* of numbers is a compendious kind of addition.

Thus the *multiplication* of 4 by 5 makes 20, i. e. four times five amounts to twenty; which algebraiſts expreſs thus, $4\times5=20$.

In *multiplication*, the firſt factor, i. e. the number to be multiplied, or the multiplicand, is placed over that whereby it is to be multiplied; and the factum or product under both.

An example or two will make the proceſs of *multiplication* eaſy. Suppoſe I would know the product of 269 multiplied by 8, or 8 times 269.

Multiplicand	—	—	269
Multiplier	—	—	8
Factum, or product		—	2152

The factors being thus diſpoſed, and a line drawn underneath (as in the example), I begin with the multiplicator thus: 8 times 9 make 72, ſet down 2, and carry 7 tens, as in addition; then 8 times 6 make 48, and 7 I carried, 55; ſet down 5, and carry 5; laſtly, 8 times 2 make 16, and with 5 I carried 21, which I put down: ſo that coming to number the ſeveral figures placed in order, 2, 1, 5, 2, I find the product to be 2152.

Now ſuppoſing the factors to expreſs things of different ſpecies, viz. the multiplicand men, or yards, and the multiplier pounds; the product will be of the ſame ſpecies with the multiplicator. Thus the product of 269 men or yards, multiplied by 8 pounds or pence, is 2152 pounds or pence; ſo many of theſe going to the 269, at the rate of 8 a piece. Hence the vaſt uſe of *multiplication* in commerce, &c.

If the multiplicator conſiſts of more than one figure, the whole multiplicand is to be added to itſelf; firſt, as often as the right-hand figure of the multiplicator ſhews, then as often as the next figure of the multiplicator ſhews, and ſo on. Thus 421×23 is equal to 421×3, and alſo 421×20. The product ariſing from each figure of the multiplicator, multiplied into the whole multiplicand, is to be placed by itſelf in ſuch a manner, that the firſt or right-hand figure thereof may ſtand under that figure of the multiplicator from which the ſaid product ariſes. For inſtance:

Multiplicand	—	—	421
Multiplicator	—	—	23
Particular product of 421×3		—	1263
Particular product of 421×20		—	842
The total product		—	9683

This diſpoſition of the right-hand figure of each product follows from the firſt general rule; the right hand figure of each product being always of the ſame denomination with that figure of the multiplicator from which it ariſes.

Thus, in the example, the figure 2 in the product 842 is of the denomination of tens, as well as the figure 2 in the multiplicator. For 1×20 (that is, the 2 of 23)$=20$, or 2 put in the place of tens, or ſecond place.

Hence, if either of the factors have one or more cyphers on the right-hand, the *multiplication* may be performed without regarding the cyphers, till the product of the other figures be found: to which they are to be then affixed on the right. And if the multiplicator have cyphers intermixed, they need not be regarded at all. Inſtances of each follow:

32	358		1|0		24|00		8013
10	6|000		1|0		3|0		5006
320	2148000		10 0		72000		48078
							40065
							4011 3078

Thus much for an idea of *multiplication*, where the multiplicator conſiſts wholly of integers; in the praxis whereof, it is ſuppoſed, the learner is appriſed of the product of any of the nine digits multiplied by one another, eaſily learnt from the common table, or otherwiſe.

2

There are alſo ſome abbreviations of this art. Thus to multiply a number by 5, you need only add a cypher to it, and then halve it. To multiply by 15 do the ſame, then add both together. The ſum is the product.

Expedients for the more eaſy and expeditious multiplying large ſums are ſliding rules, and Neper's bones. The want of which may be ſupplied by tabulating the multiplicand.

Where the multiplicator is not compoſed wholly of integers, as it frequently happens in buſineſs, where pounds are accompanied with ſhillings and pence; yards with feet and inches; the method of procedure, if you multiply by a ſingle digit, is the ſame as in ſimple numbers, only carrying from one denomination to another, as the nature of each ſpecies requires. E. gr. to multiply 123*l.* 14*s.* 9*d.* 3*q.* by five: ſay, $5\times3q.=15q.$ that is, 3*d.* 3*q.* write down the 3*q.* and proceed, ſaying $5\times9=45d.$ that is, 3*s.* 9*d.* to which add 3*d.* ſet down 0, and proceed in the ſame manner through the reſt.

If you multiply by two or more digits, the methods of procedure are as follow: ſuppoſe I have bought 37 ells of cloth at 13*l.* 16*s.* 6*d.* per ell, and would know the amount of the whole. I firſt multiply 37 ells by the 13*l.* in the common method of *multiplication* by integers, leaving the two products without adding them; then multiply the ſame 37 ells by 16*s.* leaving, in the like manner, the two products without adding them. Laſtly, I multiply the ſame 37 by the 6*d.* the product whereof is 222*d.* which divided by 12 (ſee DIVISION), gives 18*s.* 6*d.* and this added to the products of the 16*s.* the ſum will be 610*s.* 6*d.* the amount of 37 ells at 16*s.* 6*d.* the ell. Laſtly, the 610*s.* 6*d.* are reduced into pounds by dividing them by 20 (ſee REDUCTION): upon adding the whole, the amount of 37 ells at 13*l.* 16*s.* 6*d.* will be found as in the following:

37 ells	37 ells	37 ells
At 13 pounds.	At 16 ſhillings.	At 6 pence.
111	222	222
37	37	
30 10 6	18 6	
Product 511 10 6	610 6	

Or thus: ſuppoſe the ſame queſtion; reduce the 13*l.* 16*s.* into ſhillings, the amount will be 276*s.* reduce 276*s.* into pence, adding 6, the amount will be 3318*d.* Multiply the 37 ells by 3318, the amount will be 122766*d.* which divided by 12, and the quotient 10230*s.* 6*d.* reduced into pounds by cutting off the laſt figure on the right, and taking half of thoſe on the left, yields 511*l.* 10*s.* 6*d.* the price of the 37 ells, as before.

Though by theſe two methods any *multiplication* of this kind may be effected, yet the operations being long, we ſhall add a third much ſhorter. Suppoſe the ſame queſtion: multiply the price by the factors of the multiplicator, if reſolvable into factors: if not, by thoſe that come neareſt it: adding the price for the odd one, or multiplying it by what the factors want of the multiplier. So, the work will ſtand thus; 37 ells at 13*l.* 16*s.* 6*d.* $6\times6=36+1=37$:

Therefore —

	82	19 0
	497	14 0
	13	16 6
	511	10 6

The price of the 37 ells.

But the moſt commodious is the fourth method, which is performed by aliquot and aliquant parts—where you are to obſerve by the way, that *aliquot parts* of any thing are thoſe contained ſeveral times therein, and which divide without any remainder; and that *aliquant parts* are other parts of the ſame thing compoſed of ſeveral aliquot parts.

To MULTIPLY *by aliquot parts*, is, in effect, only to divide a number by 2, 3, 4, 5, &c. which is done by taking a 2d, 4th, 5th, &c. from the number to be multiplied. Example: To multiply, v. gr. by 6*s.* 8*d.* Suppoſe I have 347 ells of ribband at 6*s.* 8*d.* per ell.

Multiplicand	—	347 ells.
Multiplicator	—	6*s.* 8*d.*
Product	—	115*l.* 13*s.* 4*d.*

The queſtion being ſtated, take the multiplicator, which, according to the table of aliquot parts, is the third; and ſay the third of three is 1, ſet down 1; the third of 4 is 1, ſet down 1, remains 1, that is 1 ten, which added to 7, makes 17; the third of 17 is 5; remain 2 units, i. e. two-thirds, or 13*s.* 4*d.* which place after the pounds. Upon numbering the figures 1, 1, and 5, integers, and

13*l.*

13*s.* 4*d.* the aliquot part remaining, I find the sum 115*l.* 13*s.* 4*d.*

For MULTIPLICATION *by aliquot parts*: Suppose I would multiply by the aliquot part 19. I first take for 10, half the multiplicand; then for 5, which is the fourth, and laſtly, for 4, which is the 5th. The products of the three aliquot parts that compoſe the aliquot part, being added together, the ſum will be the total product of the *multiplication*, as in the following example; which may ſerve as a model for *multiplication* by any aliquot part that may occur.

Multiplicand	——	356 ells.
Multiplier	——	19.
		178*l.* for 10.
		89*l.* for 5.
		71*l.* 4*s.* for 4.
Product	——	338*l.* 4*s.*

MULTIPLICATION, *for the proof of*. The operation is right when the product divided by the multiplier quotes the multiplicand; or divided by the multiplicand, quotes the multiplier. A readier way, though not abſolutely to be depended on (ſee ADDITION), is thus: add up the figures of the factors, caſting out the nines; and ſetting down the remainders of each; theſe multiplied together, out of the factum caſt away the nines, and ſet down the remainder: if this remainder agree with the remainder of the factum of the ſum, after the nines are caſt out; the work is right.

MULTIPLICATION, *craſs*, otherwiſe called *duodecimal arithmetic*, is an expeditious method of multiplying things of ſeveral ſpecies, or denominations, by others likewiſe of different ſpecies, &c. *e. gr.* ſhillings and pence by ſhillings and pence; feet and inches by feet and inches. This is much uſed in meaſuring, &c. The method is thus,

Suppoſe 5 feet 3 inches to be multiplied by 2 feet 4 inches: ſay, 2 times 5 feet is 10 feet, and 2 times 3 is ſix inches: again, 4 times 5 is 20 inches, or 1 foot 8 inches; and 4 times 3 is 12 parts, or 1 inch: the whole ſum makes 12 feet 3 inches. In the ſame manner you may manage ſhillings and pence, &c.

MULTIPLICATION, in *Algebra*. To multiply algebraic quantities, we muſt attend not only to the quantities themſelves, but alſo to their ſigns.

The general rule for the ſigns is, that when the ſigns of the factors are like, (*i.e.* both + or both −) the ſign of the product is +; but when the ſigns of the factors are unlike, the ſign of the product is −.

Then if the quantities to be multiplied be ſimple quantities, find the ſign of the product by the laſt rule; after it place the product of the coefficients, and then ſet down all the letters after one another, as in one word.

If the factors be compound quantities, multiply every part of the multiplicand by all the parts of the multiplier, taken one after another, and then collect all the products into one ſum; which will be the product required. See Maclaurin, Saunderſon, Hammond, or any other elementary writers.

The reaſon of the rule here given for the ſigns of the product, viz. that + by +, or − by − give +, and that + by −, or − by + give −, is apt to perplex beginners. But if it be conſidered, that in all *multiplication* the multiplicator is, ſtrictly ſpeaking, a number, the difficulty ſoon vaniſhes; for, 1. When any poſitive quantity $+a$ is multiplied by any poſitive number $+n$, the meaning is, that $+a$ is to be taken as many times as there are units in n, and therefore the product is evidently $+na$ or an, the poſitive ſign being omitted.

2. When $-a$ is multiplied by n, then $-a$ is taken as often as there are units in n, and the product muſt be $-an$.

3. As *multiplication* by a poſitive number implies a repeated addition, *multiplication* by a negative implies a repeated ſubtraction; ſo that when $+a$ is to be multiplied by $-n$, the meaning is, that $+a$ is to be ſubtracted as often as there are units in n, therefore the product muſt be negative, being $-na$.

4. When $-a$ is to be multiplied by $-n$, then $-a$ is to be ſubtracted as often as there are units in n; but by the rules of ſubtraction, to ſubtract $-a$ is equivalent to adding $+a$, and conſequently the product is $+na$.

The ſecond and fourth caſes may be thus illuſtrated, by the import and meaning of the ſigns + and −, $+a-a$ muſt be $=0$. Therefore if we multiply $+a-a$ by n, the product muſt vaniſh, or be nothing; becauſe the factor $a-a=0$. The firſt term of the product is $+an$ by caſe 1. therefore the ſecond term of the product muſt be $-an$, which deſtroys $+an$; ſo that the whole product muſt $+an-an=0$. Therefore $-a$ multiplied by $+n$ gives $-an$.

In like manner, if we multiply $+a-a$ by $-n$, the firſt term of the product being $-an$, the latter term of the product muſt be $+an$, becauſe the two together muſt deſtroy each other, or their amount be $=$, ſince one of the factors $a-a=0$. Therefore $-a$ multiplied by $-n$, muſt give $+an$. See Maclaurin's Algebra, part i. chap. 4. Saunderſon's Algebra, vol. i. p. 37. And Barrow's Euclid. Schol. Prop. 10. Elem. 2.

EXAMPLES.

Mult.	$+a$	$-2a$	$+bc$	$-8x$	$+3ab$
By	$+b$	$+4b$	$-5a$	$-4x$	$-5ac$
Products	$+ab$	$-8ab$	$-30ax$	$+32ax$	$-15a^2bc$

$a+b$	$2a-3b$	$2x-4b$
$a+b$	$4a+3b$	$2x+4b$
a^2+ab	$8a^2-12ab$	$4x^2-8xb$
$+ab+b^2$	$+10ab-15b^2$	$+8xb-16b^2$
$a^2+2ab+b^2$	$8a^2-2ab-15b^2$	$4x^2-16b^2$

x^2-xz	a^2+ab+b^2
$x+a$	$a-b$
x^3-ax^2	$a^3+a^2b+ab^2$
$+ax^2-a^2x$	$-a^2b-ab^2-b^3$
x^3-a^3x	a^3-b^3

See EXPONENT.

MULTIPLICATION, in *Geometry*, or in *lines*, is effected by ſuppoſing a line *ab* (*Tab.* III. *Geometry*, *fig.* 61.) called the *deſcribent*, moving perpendicular along another *c*, called the *dirigent*.

For, by this means, the deſcribent forms the rectangle *adcb*; and if it be divided, together with the dirigent, into any number of equal parts, it will, by its motion, deſcribe as many little rectangles as the units in the deſcribent and dirigent will produce, when multiplied into one another, viz. 21. For when the line *ab* hath moved over one part of *ad*, it will, by its three parts, have deſcribed the three little rectangles in the firſt column; when it comes to 2, it will have deſcribed three more. And this is the reaſon why *multiplication*, in the Latin tongue, is uſually expreſſed by the word *ductus*, *drawn*; (and from hence alſo comes *product*) as if *ab* were multiplied by *bc*, they ſay, *ab ductus in bc*; becauſe the deſcribent is led, as it were, or carried along in an exact poſture upon the dirigent, and by that means deſcribes the rectangle; ſo that the rectangle and product are the ſame in geometry.

Now, as in all *multiplication* unity is to one factor as the other is to the product, *multiplication* in lines may be performed thus. Let *ab* (*fig.* 62.) be to be multiplied by *ad*. Make any angle at pleaſure; on one of the legs ſet off $ac=$ to unity, and on the ſame leg ſet off *ad*, the multiplicator (3); then ſet the multiplicand *ab* (2) from *a* on the other leg of the angle; draw *cb*, and parallel to it, through *d*, draw *de* (6). I ſay, *de*, or 6, is the product: for $ac : ab :: ad : de$.

MULTIPLICATION *of plants*. See FECUNDITY, and PLANTS.

MULTIPLICATIVES. See NUMERALS.

MULTIPLIER, in *Arithmetic*, the number multiplying, or MULTIPLICATOR.

MULTIPLICATOR, in *Arithmetic*, a number multiplying another called the *multiplicand*.

The largeſt number is ordinarily made the multiplicand, and placed above the ſmaller, or *multiplicator*; but the reſult is the ſame, which ſoever of the numbers be made multiplicand or *multiplicator*; 4 times 5, and 5 times 4, making the ſame ſum.

MULTIPLYING, in the *Animal Oeconomy*, the producing of one's like.

Mankind *multiplied* at a prodigious rate before the flood. Rabbets, fiſh, and moſt inſects, *multiply* incredibly; the ſingle milt of a cod, examined with M. Leewenhoeck's microſcope, was found to contain more ova than there are animals on the face of the earth. See *Fecundity of* FISH. M. Dodart has ſeveral diſcourſes on the multiplication of plants, in the Memoirs of the Royal Academy of Sciences. He has examined the beech-tree, particularly, with this view, and found its increaſe to ſurpaſs all imagination.

MULTIPLYING, in *Arithmetic*, is the finding a number which contains the multiplicand as often as there are units in the multiplier.

The rule of three conſiſts in *multiplying* the third term by the ſecond, and dividing the product by the firſt. See RULE *of three*.

MULTIPLYING-*glass*, a lens, or glass, in which objects appear increased in number.

A *multiplying-glass*, called also a *polyhedron*, is a glass formed or ground into several planes, or faces, making angles with one another; through which the rays of light, issuing from the same point, undergo different refractions, so as to enter the eye from every surface in a different direction; as if they came from several points.

And thus the same point is seen in several imaginary foci; and therefore appears *multiplied*. For the phænomena and laws of *multiplying-glasses*, see POLYEDRON.

MULTISILIQUOUS *plants* are the same with *corniculate plants*; viz. those which, after each flower, have divers distinct, slender, and frequently crooked, siliquæ, or pods, wherein their seed is contained; and which, when they ripen, open of themselves, and let the seeds drop.

MULTITUDE, *multitudo*, an assemblage, or collection, of a great number of things, or persons.

Multitude is properly the abstract whereby things are said to be *many*.

In which sense, *multitude* may be considered as *number*; and stands opposed to *unity*.

In law, some will have *multitude* to imply at least ten persons; but Sir Edward Coke says, he could never find it restrained, by the common law, to any certain number, but always left to the discretion of the judges.

MULTIVALVES, in *Natural History*, the name of a general class of shell-fish, distinguished from the univalves, which consist of only one shell, and the bivalves, which consist of two, by their consisting of three or more shells.

Of these there are much fewer species than either of the univalve or bivalve class. A late accurate French author has ranked all the species under six genera, which are these. 1. The *ecbinus*, or sea-eggs. 2. The *vermiculi*, or sea-worms. 3. *Balani*, or center-shells. 4. The *polithecæ*, or thimble-shells. 5. The *anatifer æ*, or goose-shells. And, 6. The *pholades*. Hill. Nat. Echaire. part ii. p. 135. All these are under their several heads.

A MULTO *fortiori*, *or a minore ad majus*, is a way of argumentation often used by Lyttelton, whose force is thus: if it be so in a small matter, much more is it so in a matter of an ancient right.

MULTONES *nummi*, in our *Ancient Writers*, an old coin of gold, having an *Agnus Dei*, sheep, or lamb, on the one side, and from that impression called *multones*. This coin was much common in France, and sometimes current in England. Patent 33 Edw. I. cited by the learned Spelman.

MULTUM, in *Arithmetic*. If A be one, B one, C one, D one, &c. and B, C, and D, be not the same with A; A, B, C, and D, are *multa*, or *plura*, *many*. Wallius.

MULTURA *spiscat*. See MULTA.

MULUD, in the *Materia Medica*, a word used by Avicenna and Serapion to express a sort of litharge, called by the Greeks *molybditis*, as seeming to partake of the nature of lead alone, not of gold or silver, or any other metal, as they thought the aggrites and chrysites did. This *molud*, or molybditis, was the least in esteem of all the kinds of litharge, and was of a dusky greyish white colour. It seems to be the same that Dioscorides means by *polia* and *polia*, and sometimes by *litharguros Sicelicus*, from the place whence it was brought.

MUM, a wholsome kind of malt liquor, chiefly prepared in Germany.

The process of making *mum*, as recorded in the townhouse of Brunswick, the place of most note for this liquor, is as follows.

Take forty-three gallons of water that has been boiled to the consumption of a third part; brew it with seven bushels of wheaten malt, one bushel of oat malt, and one bushel of ground beans; when it is tunned, let not the hogshead be too full at first; and as soon as it begins to work, put into it of the inner rind of fir three pounds, tops of fir and birch each one pound, carduus benedictus three handfuls, flowers of rota solis one handful or two; burnet, betony, marjoram, avens, pennyroyal, wild thyme, of each a handful and a half; of elder-flowers two handfuls, or more; seeds of carduus or blessed thistle thirty ounces, barberries bruised one ounce; put the herbs and seeds into the vessel when the liquor has worked a while; and, after they are added, let the liquor work over the vessel as little as may be; then fill it up. Lastly, when it is stopped, put into the hogshead ten new-laid eggs unbroken or cracked, stop it up close, and drink it at two years end.

Our English brewers use cardamom, ginger, and saffafras, instead of the inner rind of fir; and add also walnut-roots, madder, red saunders, and elecampane.

Every barrel of *mum* imported pays a duty of 25*s.* and by 12 Ann. stat. 1. c. 2. and 13 Geo. c. 7. every barrel of *mum* made or imported is liable to an additional duty of 10*s.*

MUMMING, from the Teutonic *mummen*, *to mimic*; antic diversions in the Christmas holidays, to get money or good cheer.

MUMMY, *mumia*, a carcase, or body, embalmed or dried in the manner of the ancient Egyptians.

Menage, after Bochart, derives the word *mummy* from the Arabic *mumia*; of *maar*, *myrr*; Salmasius, from *mumiam*, a kind of perfume; though others hold, that, in the Arabic tongue, the word *mumia* signifies a body embalmed, or aromatized.

Properly speaking, *mummy* is not the flesh of the deceased, but the composition wherewith it is embalmed; but, in common acceptation, *mummy* is also used for the body.

The preparation of *mummy* is of so old a standing, that it was in use in Egypt before the time of Moses. The coffin in which the *mummy* is contained was to be of sycamore wood, which *is* found to keep sound for the space of three thousand years; but the tree, properly thus called, was very different from our sycamore.

Mummy is said to have been first brought into use in medicine by a Jewish physician, who wrote, that flesh thus embalmed was good for the cure of divers diseases, and particularly for bruises, to prevent the blood's gathering and coagulating. The Turks prevent the exportation of *mummy* into Europe, as much as possible.

There are two kinds of bodies denominated *mummies*. The first are only carcases, dried by the heat of the sun, and by that means kept from putrefaction: these are frequently found in the dry sands of Libya. Some say, they are the bodies of deceased people buried there on purpose to keep them entire without embalming; others, that they are the carcases of travellers, &c. who have been overwhelmed with clouds of sand raised by the hurricanes frequent in those deserts. Be that as it will, these *mummies* are of no use in medicine, and are only preserved as curiosities.

The second kind of *mummies* are bodies taken out of the pits or catacombs near Cairo, wherein the Egyptians deposited their dead after EMBALMING. These constitute the *mummy* once so much valued, and to which such extraordinary virtues are ascribed.

It is said, that all the *mummy* sold in the shops, whether brought from Venice or Lyons, or even directly from the Levant by Alexandria, is factitious, and the work of certain Jews, who, knowing the value the Europeans set on the Egyptian *mummy*, counterfeit it by drying carcases in ovens, after having prepared them with powder of myrrh, caballin aloes, Jews pitch, black pitch, and other coarse or unwholsome drugs.

The French charlatans, it seems, have likewise got the art of preparing *mummies*. Their method is simple enough: out of the carcase of a person hanged, they take the brain and entrails, and dry the rest in an oven, flooping it in pitch, and other drugs; and this they sell for right Egyptian *mummy*.

There are found at this time in Poland a kind of natural *mummies*, or human bodies, preserved without the assistance of art. These lie in considerable numbers in some of the vast caverns in that country. They are dried, with the flesh and skin shrunk up almost close to the bones, and are of a blackish colour. In the wars which several ages ago laid waste that country, it was common for parties of the weaker side to retire into these caves, where their enemies, if they found it out, suffocated them by burning straw, &c. at the mouth of the cavern, and then left the bodies; which, being out of the way of injuries from common accidents, have lain there ever since.

Parœus has a very curious treatise of *mummies*, wherein he shews the abuses thereof; and makes it appear, that they can never be of any real medicinal use.

Matthiolus is of the same opinion, after Serapion. Both these authors take even the Egyptian *mummies* to be no more than bodies embalmed with pissasphaltum.

MUMMY, *mumia*, is more particularly used for the liquor or juice oozing from human bodies aromatized and embalmed, gathered in the sepulchres. This is the *mummy* chiefly spoken of among the ancient writers.

MUMMY also denotes a medicinal drug, or a viscous composition, partaking of bitumen and pitch, found in the mountains and forests of Arabia, and other hot countries in the East; much used in embalming of dead bodies.

Dioscorides speaks of *mummy* found on the sea-coast near Epidaurus, brought thither by the torrents from the Ceraunian mountains, and there dried by the sun into huge masses.

It smells like bitumen mixed with pitch. The people thereabouts call it *mineral wax*. In Latin, or rather Greek, it is called PISSASPHALTUS.

MUMMY, *mumia*, is also used, by some physicians, for a supposed implanted spirit, found chiefly in carcases, when the infused spirit is fled.

The infused spirit is sometimes also called *mummy* in li-

ing subjects; and both the one and the other are supposed to serve in TRANSPLANTATION.

A plant, for inſtance, bringing this *mumia* from one ſubject to another, the *mumia* joins and unites itſelf immediately with the *mumia* or ſpirit of the new ſubject; and from this union ariſes a natural and common inclination between the two ſubjects. And on this principle they account for ſympathetic or magnetic cures. But this whole doctrine is now deſervedly ridiculed and exploded.

MUMMY is alſo uſed, among *Gardeners*, for a ſort of wax uſed in the planting and grafting of trees.

Agricola directs the preparation thereof as follows: take one pound of common black pitch, and a quarter of a pound of common turpentine; put them together in an earthen pot, and ſet them on fire in the open air, having a cover ready to quench the mixture in time: the matter is to be thus alternately lighted and quenched, till all the nitrous and volatile parts be evaporated. To this a little common wax is to be added; and the compoſition is then to be fit by for uſe.

To apply it in the dreſſing of roots of trees, melt it, and dip in the two ends of the pieces of root, one after another; then put them in water, and plant them in the earth, the ſmall end downward, ſo that the larger may appear a little way out of the earth, and ſo may have the benefit of the air; then preſs the earth hard down upon them, that they may not receive too much wet. Miller.

MUNDANDIS *curis & curialis*. See VICIL.

MUNDIBURDUS. See ADVOCATE.

MUNDIC, a name for marcaſite; a kind of mineral globe, found in the tin-mines, and elſewhere; ſometimes white, yellow, or green; and ſometimes of a dark brown colour. It is of an arſenical nature. See Geoffroy, in Mem. Acad. Scienc. 1738, p. 107, edit. Par. It is frequently called *mixy*.

The *mundic ore* is eaſily diſtinguiſhed by its glittering, and ſometimes by its diſcolouring the fingers. Some ſay, it feeds the tin; and yet they allow, that, where there is much *mundic*, there is little or no tin.

What is called *mundic* in Cornwall, frequently contains a large portion of copper.

The fteams of the *mundic* are very troubleſome to the miners; yet it is found a good vulnerary; and the miners uſe no other remedy for wounds, but waſhing them in water that runs from the *mundic ore*. See MARCASITE.

MUNDIFICATIVES, or MUNDIFIERS, in *Medicine*, denote *cleanſers*, *purifiers*, or *detergents*.

Mundificative plaſters, or unguents, are ſuch as deterge and dry, and thus cleanſe ulcers of two kinds of matter, viz. *pus*, and *ſanies*.

The chief ingredients in *mundificative* unguents are, gentian, ariſtolochia, enula campana, and the vulnerary herbs.

MUNDUS, *world*. See WORLD.

MUNDI, *anima*. See ANIMA.

MUNDUS *patens*, among the Romans, a ſolemnity performed in a little temple of a round form; and dedicated to *Dis*, and the infernal gods.

It was opened only three times in a year, *viz.* on the day after the VULCANALIA, the fourth of October, and the ſeventh of the *Ides* of November, during which days the Romans believed that hell was open; and therefore they never offered battle on thoſe days, liſted no ſoldiers, never put to ſea, nor married.

MUNDUYGUACU, in *Botany*, a name of the *nux cathartica* of the Weſt Indies, a kind of great ricinus, or palma Chriſti.

MUNERARIUS. See DELIGNATOR.

MUNGATHIA, in *Zoology*, the name given by ſome to a ſpecies of Indian ferret, of a reddiſh grey colour, called alſo *mungo*.

MUNGO, in *Zoology*, the name of an American animal of the ferret kind, called by authors *viverra Indica ex griſeo-rufeſcens*, or the reddiſh grey Indian ferret. Some call it alſo *mungathia*.

MUNICIPAL, MUNICIPALIS, or MUNICEPS, compounded of *munus*, *office*, and *capio*, *I take*, or *hold*, an appellation given to the inhabitants of the municipia, or municipal cities.

In the Roman law, *municipal* denotes a perſon veſted with the rights and privileges of a Roman citizen.

This title the Romans frequently beſtowed on foreign cities and people; and, in effect, it was little more than a title.

MUNICIPAL *cities*, *municipia*, were thoſe whoſe inhabitants were capable of civil offices in the city of Rome.

Theſe, however, according to Mariana, came ſomewhat ſhort of the privileges of the colonies. They were towns or cities, which had the citizenſhip of Rome beſtowed upon them, and yet ſtill lived according to their own laws and conſtitutions; whereas the colonies were governed by the Roman laws.

They had no ſuffrages, or votes, at Rome, but were left to be governed by their own laws and magiſtrates. It is true, ſome few *municipal* cities, by particular merit, &c. obtained the liberty of votes; which occaſioned that received diſtinction of *municipium ſine ſuffragii*, & *municipium cum ſuffragio*.

They were ſo called, becauſe *munera ſunt honorarii participes*; but by *munus honorarium* was meant no more than the bare appellation of a Roman, whereby they were privileged to fight in a legion, as denizens; and not in auxiliary bands, as aſſociates. The firſt who had this honour were the Cerites.

MUNICIPAL, among us, is now applied to the cuſtomary laws, that obtain in any particular city or province, and which have no authority in the neighbouring places. See LAW.

MUNICIPAL *officers* are thoſe elected to defend the intereſts of cities, their rights and privileges, and to maintain order and good policy: as mayors, theriffs, bailiffs, bailiffs, &c.

In Spain, the *municipal* offices are bought; in England, they are obtained by election.

MUNIMENTS, or MUNIMENTS, the evidences, or writings, whereby a man is enabled to defend the title of his eſtate.

Wrangford ſays, the word *muniment* includes all manner of evidence, deeds, charters, &c.

MUNIMENT-*houſe*, a little ſtrong apartment in cathedral and collegiate churches, caſtles, colleges, or the like, deſtined for keeping the ſeal, evidences, charters, &c. of ſuch church, college, &c. called *muniments*, or *minuments*.

MUNIMINA, formed of the Latin *munio*, *I defend* or *ſtrengthen*, the grants or charters of kings and princes to churches; ſo called, becauſe *eam vis muniuntur* againſt all thoſe who would deprive them of thoſe privileges.

MUNIONS, in *Architecture*, the ſhort upright poſts, or bars, which divide the ſeveral lights in a window-frame.

MUNITION, or AMMUNITION, the proviſions wherewith any place is furniſhed, in order for defence, or wherewith a veſſel is ſtocked for a voyage; or thoſe that follow a camp for its ſubſiſtence. See AMMUNITION.

MUNITION-*bread* is the proportion of bread diſtributed every day to the ſoldiers of a garriſon, or army. Each officer is allowed ſo many rations of *munition-bread*.

MUNITION-*ſhips*, in the *Navy*, thoſe which have ſtores on board, to ſupply the neceſſaries to a fleet of men of war at ſea.

In the time of an engagement, all the *munition-ſhips* and victuallers attending the fleet are to take their places and proper ſtations in the rear of all the reſt, and not engage in the fight, but attend ſuch directions as ſhall be ſent unto them, at all times, by the admiral.

MUNNY-*ſtuff*, in *Natural Hiſtory*, a name given by the natives of the Eaſt Indies to a ſpecies of red orpiment, which they have plentifully there. It is of a glowing colour, and has a great many ſhining ſpangles in it. They give this in fevers, after it has been calcined: it firſt melts in the fire, and then emits copious white fumes, ſmelling like thoſe of arſenic. Theſe are ſuppoſed to contain the poiſonous parts of it, and it then becomes a ſafe internal medicine, and is given with great ſucceſs.

MUNTINGIA, in *Botany*, a genus of the *polyandria monogynia* claſs. Its characters are theſe: the empalement of the flower is cut into five ſegments; the flower has five heart-ſhaped petals inſerted in the empalement, which ſpread open like a roſe, and it has a great number of ſtamina; in the center is ſituated a roundiſh germen, having no ſtyle, but is crowned by a ſtigma, divided into many parts; the germen turns to a berry with five cells, filled with many ſeeds. Miller enumerates three ſpecies, natives of the Weſt Indies; but Linnæus mentions only one.

MUNYCHIA, *Μουνυχια*, in *Antiquity*, an anniverſary ſolemnity at Athens, upon the ſixteenth of the month *Munychion*, in honour of Diana, ſurnamed *Munychia*.

MUNYCHION, *Μουνυχιων*, in *Chronology*, the tenth month of the Athenian year. It contained twenty-nine days, and anſwered to the latter part of our March and beginning of April. See MONTH.

It had its name from the feſtival *Munychia*, kept in it.

MUPHTI, or MUFTI, the chief or patriarch of the Mahometan religion, reſiding at Conſtantinople.

The *muphti* is the ſovereign interpreter of the Alcoran, and decides all queſtions of the law.

He takes place of the baſhaws; and his authority is often terrible to the grand ſignior himſelf. It is he who girds on the ſword to the grand ſignior's ſide; which ceremony anſwers to the coronation of our kings.

MURÆNA, in the Artedian ſyſtem of *Ichthyology*, the name of a genus of fiſhes, the characters of which are theſe: they are of the malacopterygious or ſoft-finned kind; the branchioſtege membrane on each ſide contains

ten

ten slender and curved bones; but the skin is so thick, that these are not easily distinguished before that is pulled off: the foramina of the nostrils are two, and are placed in the very summit of the snout, one on each side: the body is long and cylindric; in some species there are three fins, in others two, and in others only one.

The species of *murænæ* enumerated by Artedi, are six. See EEL.

The *murænæ* in the Linnæan system is a genus of the *apodes*, distinguished by a smooth body, tubulous nostrils, ten bones in the branchiostege membrane, eyes covered with a skin, a roundish body, and spiracles near the head or pectoral fins, comprehending seven species.

It is to be observed, that the dictionaries usually give us the word lamprey, as the English of *muræna*; but the *muræna* and lamprey, called by the Latin authors *lampetra*, are two very different fishes. See LAMPREY.

Muræna is originally Greek, and is derived from the verb μυειν, *to flow*, or be slippery, and expresses the manner in which its slipperyness makes it roll about, and escape the catcher, by slipping through his fingers.

MURÆNA is used by Albertus for the common small lamprey, the *lampetra parva fluviatilis* of authors. This is one of the petromyzæ of Artedi, and is distinguished by the having only one row of very small teeth in the verge of the mouth, beside the larger lower ones.

MURAGE, *muragium*, in our *Customs*, a reasonable toll to be taken of every cart or horse coming laden into a city or town, for the building or repairing the walls thereof.

MURAL, something belonging to a *wall*; which the Latins call *murus*.

MURAL *crown*, among the ancient Romans. See CROWN.

MURAL *arch* is a wall, or walled arch, placed exactly in the plane of the meridian, i. e. upon the MERIDIAN *line*, for the fixing of a large quadrant, sextant or other instrument, to observe the meridian altitudes, &c. of the heavenly bodies.

Tycho Brahe was the first who used a *mural arch* in his observations; after him Hevelius, Mr. Flamsteed, De la Hire, &c. used the same means. See a description of the *mural arch* at Greenwich, constructed by Mr. Graham, in Smith's Optics, book iii. c. 7. with the improvements of Mr. Bird, in the Method of constructing *Mural* Quadrants, published by the commissioners of longitude, 1708.

MURDER. See MURTHER.

MURDERING *battery*. See BATTERY.

MURE, *counter*. See COUNTER-*mure*.

MURENGERS, two officers of great antiquity in the city of Chester; being two of the principal aldermen chosen yearly to see the walls kept in good repair, and to receive a certain toll and custom for the maintenance thereof.

MUREX, in *Natural History*, the name of a genus of shell-fish, of the *testacea* order of worms in the Linnæan system, the characters of which are these: it is an univalve spiral shell, beset with sharp spines and tubercles, with a rough clavicle exerted near the summit in most species, but in some depressed; the mouth is always expanded, and sometimes has teeth, sometimes not; the lip is sometimes thickened, sometimes elated or folded, or jagged; and the columella is sometimes rough, sometimes smooth. The animal inhabiting this shell is the limax. See *Tab. of Shells*, N° 13.

Notwithstanding that this is the general character of the *murex*, and that all the species have an oblong mouth, and the body covered with tubercles, there are, under this extensive character, four specific variations of figure, which are very observable. The first is seen in the aluted *murex*, which has no spines; the second is in the spider shell, which has very remarkable series of fingers or hooks; the third is the helmet-shell, which is a true triangular *murex*; the last is a furrowed *murex*, which has no wings, nor protuberances, nor spines, but has a flat head, and an oblong dentated mouth. Hist. Nat. Eclairc. p. 290. Aldrovand. Rondelet. Rumphius.

On the first examination of several of the species of helmet-shell, the outer coat of which is smooth, it would be natural to refuse them any place among the *murex* class; but when we see the oblong shape of the mouth, and find that it is furnished with teeth, and afterwards observe the rudiments of tubercles which are to be seen on the mouth side, we shall perceive that they are all true *murices*, though less prickly than the others.

The ancients were furnished with their finest purple dye from a fish of the *murex* kind, and therefore expressed the purple colour by the word *murex*.

The family of the *murex* being very extensive, it may be proper to divide them into some separate series from the general common marks of certain numbers of the species.

1. Some have remarkably eminent tubercles and spines.
2. Some are nearly smooth, but have a rough clavicle, and a crooked beak. 3. Some have digitated lips. And, 4. Some have aluted and laciniated lips. Linnæus enumerates no less than sixty-one species of the *murex*.

MUREX, among the ancient Romans, a caltrap or iron instrument with sharp points every way, used as a defence against the enemies horse.

MUREX *marinus*, a name given by some authors to the genus of shells, known at this time under the name of *porcelains* and *cowrie veneris*. See PORCELAIN *shell*.

MURINA, or MURINES, *vinum murinum*, in *Antiquity*, a delicious sweet wine, medicated with spices. It was a kind of HIPPOCRAS, and the usual drink of the ladies.

MURING, the walling, or raising the walls of a building. See WALL.

MURORUM *domificus*. See DOMESTICUS.

MURRA, among the *Ancients*, a fossile substance found in Parthia and Carmania, of a fine smell, and beautiful variety of colours.

It was thought to be some humour condensed in the earth by the heat of the sun. See MURRHINE.

MURRA was likewise a dry perfume, made of the *murra* reduced to powder.

MURRAIN, *gorgle*, a mortality, or contagious disease, among cattle.

Murrains are occasioned various ways, but principally by a hot, dry season; or rather by a general putrefaction of the air, which begets an inflammation in the blood, and a swelling in the throat, with other symptoms: the disease soon proves mortal, and is communicated from one to another.

The symptoms are, generally, a hanging down, or swelling, of the head, rattling in the throat, short breath, palpitation of the heart, staggering; abundance of gum in the eyes, &c. breath hot, and tongue flaming.

The most remarkable *murrains* we hear of, is that mentioned in the Philosophical Transactions; which spread itself through Switzerland and Germany, into Poland, &c.

The contagion seemed to propagate itself in form of a blue mist, which fell on the grass where the cattle grazed, insomuch that whole herds returned home sick; and being very dull, and forbearing their food, most of them died away in twenty-four hours time. On dissection, there were found large corrupted faleens, sphacelous and corroded tongues, &c. Those people who managed them, without a due regard to their own health, were infected by them, and died like the beasts.

Some imagine it had its rise from noxious vapours thrown out of the earth in three distinct earthquakes, perceived in the neighbourhood of the place where it began; though Dr. Stare rather thinks it owing to swarms of volatile insects. The antidote for the sound, and the medicine for the sick, were the same; viz. equal parts of soot, gunpowder, brimstone, and salt, with as much water as would wash it down: a spoonful was a dose. See OXEN.

MURRE, in *Zoology*, a name given in some parts of England to the razor-bill. See ALKA.

MURREY, in *Heraldry*, a kind of purple colour; called also *sanguine*.

MURRHINA, in *Antiquity*, a kind of sweet medicated wine.

MURRHINE, MURRHINUS, *Murrhæus*, in *Antiquity*, an appellation given to a delicate sort of ware, brought from the East, whereof cups and vases were made, which added not a little to the splendor of the Roman banquets.

Critics are divided concerning the matter of the *pocula*, or *vasa murrhina*, *murrina*, or *murrea*. Some will have them to have been the same with our porcelain, or china-ware.

The generality hold them to have been made of some precious kind of stone; which are found chiefly, as Pliny tells us, in Parthia, but more especially in Carmania. Arrian tells us, that there was a great quantity of them made at Diospolis in Egypt. This he calls another sort of *murrhina* work; and it is evident, from all accounts, that the *murrhina* of Diospolis was a sort of glass-ware, made in imitation of the porcelain or *murrha* of India. There is some difference in the accounts given by Pliny and Martial of the *murrhina vasa*. The first author says, that they would not bear hot liquors, but that only cold ones were drank out of them. The latter, on the other hand, tells us, that they bore hot liquors very well. If we credit Pliny's account, their porcelain was much inferior to our's in this particular. Some conjecture them to have been of agate, others of onyx, others of coral. Barnius, doubtless, was farthest out of the way, when he took them to be made of myrrh, congealed and hardened. Some have supposed these vessels to be made of crystal, but this is contrary to the account of all the ancients.

The Greeks had the words μυρρινος for crystal, and μυρρα for myrrh, very common among them, and therefore

fore if these vessels had been made of either of these substances, they would in some places have called them *murrhina et crystallina*. On the contrary, the most correct among them call them *murrhina et murrina*. The cups made of crystal, which were also in use at those times, were called *crystallina*, and these *murrhina* or *murrhea*, by way of keeping up the distinction; and Martial tells us, that the stone they were made of was spotted or variegated, calling them *picula maculosa murra*. And Statius mentions the crystalline and *murrhina* cups in the same sentence, but as different things, not the same. Arrian mentions also the λιθος μυρρινος, which his interpreters censure as an error of the copies, and would alter into *murrhea*, the name of the gum myrrh.

Pompey is recorded as the first who brought these *murrhina* vessels out of the East, which he exhibited in his triumph, and dedicated to Jupiter Capitolinus. But private persons were not long without them. So fond, in effect, did the Roman gentry grow of them, that a cup which held three sextaries was sold for seventy talents. T. Petronius, before his death, to spite Nero (or as Pliny expresses it, *ut morsum ejus exhæreret*), to disinherit his table), broke a basin, *trulla murrhina*, valued at three hundred talents, on which that emperor had set his heart.

MURROBATHRARII, among the Romans, a kind of perfumers. See MYRA.

MURTHER, or MURDER, the act of killing another with violence and injustice.

The word comes from the Saxon *morth*, *death*; which some will have to signify a violent death; whence the barbarous Latin *murdrum*, and *mordrum*.

Among the number of popular errors, is the notion which has obtained, that the dead body would bleed in the presence, or upon the touch, of the *murderer*.

The crime of *murder* is punished with death in almost all nations.

MURTHER, in our *Law*, is that species of criminal homicide, which denotes a wilful and felonious killing another upon prepensed malice, whether secretly or openly, and whether Englishman or foreigner, living under the king's protection.

In order to constitute the crime of *murder*, it must be committed by a person of sound memory and discretion; for a lunatic or infant are incapable of committing any crime: besides, the unlawfulness of this crime arises from the killing without warrant or excuse; and there must be also an actual killing to constitute *murder*; and this may be by poisoning, striking, starving, drowning, and a thousand other forms of death; the most detestable of which is POISON, because it is the least capable of being prevented either by manhood or forethought. There was also, by the ancient common law, one species of killing held to be *murder*, which is hardly to at this day, nor has there been any instance wherein it has been held to be *murder* for many ages past, i. e. by bearing false witness against another, with an express premeditated design to take away his life, so as the innocent person be condemned and executed. The Gothic laws punished in this case the judge, the witnesses, and the prosecutor; and, among the Romans, the *lex Cornelia, de Sicariis*, punished the false witness with death, as being guilty of a species of assassination. If a man does such an act, of which the probable consequence may be, and eventually is death; such killing may be *murder*, although no stroke be struck by himself. In order to make the killing *murder*, it is requisite that the party die within a year and a day after the stroke received, or cause of death administered; in the computation of which the whole day upon which the hurt was done shall be reckoned the first. Further, the person killed must be a reasonable creature in being, and under the king's peace, at the time of the killing; and, therefore, to kill an alien, a Jew, or an outlaw, who are all under the king's peace or protection, is as much *murder* as to kill the most regular born Englishman, except he be an alien-enemy, in time of war. To kill a child in its mother's womb, is now no *murder*, but a great misprision; but if the child be born alive, and dieth by reason of the poison or bruises it received in the womb, it is *murder* in such as administered or gave them. But as there is one case where it is difficult to prove the child's being born alive, namely, in the case of the *murder* of bastard children by the unnatural mother; it is enacted by 21 Jac. I. c. 27. that if any woman be delivered of a child, which if born alive should by law be a bastard, and endeavours privately to conceal its death, by burying the child or the like, the mother so offending shall suffer death, as in the case of *murder*, unless the can prove by one witness at least that the child was actually born dead. But it has been usual, upon trials for this offence, to require some sort of presumptive evidence that the child was born alive, before the other constrained presumption, that the child, whose death is concealed, was therefore killed by its parent, is admitted to convict the prisoner. Moreover, the killing must be committed with malice aforethought, to make it the crime of *murder*; and this malice prepense may be either express or implied in law. Express malice is, when one, with a sedate, deliberate mind, and formed design, doth kill another; which formed design is evidenced by external circumstances discovering that inward intention; as lying in wait, antecedent menaces, former grudges, and concerted schemes, to do him some bodily harm. This takes in the case of deliberate DUELLING. Also, if upon a sudden provocation one beats another in a cruel and unusual manner, so that he dies, though he did not intend his death, yet he is guilty of *murder* by express malice. Such is also a person's going deliberately with a horse used to strike, or discharging a gun, among a multitude of people. So if a man resolves to kill the next man he meets, and does kill him; it is *murder*, although he knew him not; for this is universal malice. And if two or more come together to do an unlawful act against the king's peace, of which the probable consequence might be bloodshed; as to beat a man, to commit a rape, or to rob a park, and one of them kills a man, it is *murder* in them all, because of the unlawful act, the *malitia præcogitata*, or evil intended beforehand. Further, the law will imply malice in many cases, where none is expressed; as, where a man wilfully poisons another, though no particular enmity can be proved; and in the case of a man's killing another suddenly, without any, or without a considerable provocation. Thus also if one kills an officer of justice, in the execution of his duty, or any of his assistants, knowing his authority, and the intention with which he interposes, the law will imply malice, and the killer shall be guilty of *murder*. And if one intends to do another felony, and undesignedly kills a man, this is also *murder*. In a word, we may take it for a general rule, that all HOMICIDE is malicious, and amounts to *murder*, unless where justified by the command or provision of the law; excused on a principle of accident or self-preservation; or alleviated into manslaughter, by being either the involuntary consequence of some act, not strictly lawful, or (if voluntary) occasioned by some sudden and sufficiently violent provocation.

Formerly, *murder* was restrained to a clandestine and treacherous killing. Thus, *Murdrum bonus anticipitat alicubator, absque interpellatione subsequitur, vel quamcumque effet secutus. Nunc autem illum vel, licet feritor quis murdrum fecerit, homicidium per predictum.* Leges Hen. I. *Murdrum autem propria manibus per insidiosum interfectio, postmodum mortis genere, quod Anglo murdrum appellamus.* Matth. Paris, an. 1216.

The punishment of *murder*, and that of MANSLAUGHTER, were formerly one and the same, both having the benefit of clergy; so that none but unlearned persons, who knew the guilt of it, were put to death for this enormous crime. But now, by 23 Hen. VIII. c. 1. & 1 Edw. VI. c. 12. the benefit of clergy is taken away from *murder* through malice prepense. See *Hanging in* CHAINS. Blackst. Comm. book iv. p. 194, &c.

MURTHER, *appeal of*. See APPEAL.

MURTHER, *felo*, is otherwise called *felonia de se*. See FELO *de se*.

MURTHERERS, or MURTHERING-*pieces*, are small pieces of ordnance, either of brass or iron, having chambers put in at their breeches.

They are mostly used at sea, at the half-decks of the forecastle, half-deck, &c. in order to clear the decks when an enemy boards the ship.

MURUCUJA, in *Botany*. See PASSION-*flower*.

MURZAROLT, in *Falconry*. See FALCON.

MUS, the *mouse*, in the Linnæan system of *Zoology*, makes a distinct genus of animals, of the order of the glires, and taking in the whole family of the mouse and rat-kind. The generical characters are, that the lower fore-teeth are awl-shaped; of which Linnæus enumerates twenty-one species.

Of this genus there are several distinct kinds. 1. The *common rat*, or *mus rattus* of Linnæus. This is a well known animal; its colour is a dusky brownish grey; its tail is composed of a multitude of rings, not less than a hundred and sixty. Rats destroy and devour one another; but their greatest enemy is the weasel.

2. The *water-rat*, or *mus amphibius* of Linnæus. This is much larger than the common *rat*, and is long what of a reddish brown colour; its feet have each five toes, but not webbed, as Ray and Linnæus imagined; its tail also is much shorter, and all the way of the same thickness, not tapering off, but seeming as if cut off in the middle, covered with short black hairs, and the tip whitish; its teeth are also much longer, and of a pale yellowish colour; it has a thick blunt nose, ears hid in its fur, and small eyes; it burrows on the banks of rivers and ponds,

and

and wet ditches; and feeds on small fish, and the fry of greater, on frogs, insects, and roots; and is itself the prey of the pike.

4. The *musk rat*. This, which is the *castor zibethicus* of Linnæus, is about the size of our common *rat*; its hair is long, and very thick set; its back black, and its sides and belly grey; the head is small, and the nose long and sharp, as if intended, like that of the hog, for digging up the earth; its mouth does not open very wide; its eyes are extremely small, and its jaws adorned with a number of long grey hairs all along the opening of the mouth; its tail is as long as its body, and is flatted and beset with a few scattered hairs; its feet are divided into five toes, the larger ones connected by a membrane to assist the creature in swimming, and the hinder legs are somewhat longer than the fore ones. This creature is common in Russia, and has a very strongly perfumed smell like that of musk. Ray's Syn. Quad. p. 217.

4. The common *mouse*, or *mus musculus* of Linnæus. This is too well known to need any description; but it is distinguished from the rest of the genus by its smallness, and its prominent large eyes. Its colour is a dusky grey on the back, and a whiter grey on the belly. This animal, when found white, is very beautiful; its full bright eye appearing to great advantage amidst the snowy fur.

5. The *larger mouse*. This is of twice the size of the common *mouse*, and is usually found in caverns of the earth in the fields, though sometimes also in houses; its back is of a mixed colour of black and tawny; its belly very white; and there is an even line drawn along each side, which separates the two colours; the head is longer than that of the common *mouse*, and the eyes larger and more prominent; the ears are rounder and wider; and the tail very long, and covered with short hairs, black on the upper part, and white underneath; the legs also are longer than in the common *mouse*; and there are six tubercles in the bottom of the foot.

6. The *great-headed field-mouse*, or *mus terrestris* of Linnæus. This is larger than the common *mouse*, and its head is remarkably large in proportion to its size; its nose is short and blunt; its eyes small, and not prominent; and its ears short, broad, and roundish, and almost entirely hid in the fur, which is much deeper than that of the common *mouse*. This has also a much longer body, and its tail is remarkably short, and is thinly covered with hairs; its legs also are very short; its back is of a very deep and dusky brown, with a mixture of yellow; and its belly is of a sort of lead colour, the points of all the hairs being white, and their bottoms black. It is common in dry pastures, and is abundantly distinguished from all the other kinds by the thickness of its neck and shoulders, and the shortness of its tail.

7. The *great long-tailed field-mouse*, or *mus sylvaticus* of Linnæus. This is very nearly of the size of a rat; its tail is very long, and its ears short and round; its head is thick, and the nose not sharp, as in most of these creatures, but short and rounded, and is of a deep brown, with some mixture of red at the sides; and it has a sort of beard of long hairs between the mouth and the eyes.

8. The *dormouse*, or sleeper, called *mus avellanarius* by many authors, and *glis* by Pliny. Of this there are two distinct kinds, a greater and a smaller. See DORMOUSE.

The other kinds are, 9. CITELLUS. 10. The CRICETUS. 11. The MARMOTTA. 12. The GUINEA *pig*. 13. The AGUTI. 14. PACA. 15. The *leming*, *fable* MOUSE, or Norway rat. 16. The GLIS. 17. The *Javan* HARE. 18. The *monax*, or American *marmotta*. 19. The *mus jaculus*, or JERBOA and KENGUROO. 20. The *mus pygargus*. 21. The *mus volans*, or SCIURUS. Beside these there is also another variegated kind, known by the name of the *striated Indian tree-mouse*, which is very rare, but is sometimes found in the cabinets of the curious.

MUS *Alpinus*, in *Zoology*, a name given by many authors to the mountain-rat, more commonly known by the name of the MARMOTTE.

MUS *araneus*. See SHREW.

MUS *marinus*. See APHRODITA.

MUS *Norwegicus*, in *Zoology*, the name given by authors to the Norway rat, commonly called the *leming*. See *Sable*-MOUSE, and *Norway* RAT.

MUS *Pharaonis*, *Pharaoh's rat*, a name given by the people of Egypt to the ICHNEUMON, a creature of the weasel kind, which they are very fond of for its destroying serpents, and kept tame about their houses, as we do cats.

MUS *terræ*, in *Botany*, a name given by some authors to the roots of the *bulbocastanum*, or earth-nut; it was probably at first *mus terræ radix*, the *earth-mouse's root*, and so called from the *earth-mice* or *field-mice* being very fond of them; but the word *radix* being left out, it stands only *mus terræ*.

MUSA, in *Botany*. See PLANTAIN-*tree*.

MUSADA, a name given by some chemical writers to sal *armoniac*.

MUSCA, the *fly*, in the *History of Insects*. See FLY.

MUSCA *crabroniformis* and *vespa*, names sometimes used for the hornet-fly. See ASILUS.

MUSCA *vespiformis*, the wasp-fly. See ASILUS.

MUSCA, in *Astronomy*. See APIS.

MUSCA, in *Antiquity*, a designation given to parasites, buffoons, &c. who intruded themselves into the company of those that despised them, or found means to be admitted to entertainments where they were not welcome.

MUSCADINE, a rich wine, of the growth of Provence, Languedoc, Cividad, &c.

The word, as well as the liquor, is French: some fetch its original from *musk*, the wine being supposed to have a little of the smell of that perfume: others from *mosca*, a *fly*, because the flies are extremely fond of its grapes; as the Latins had their *vinum apianum*, so called, *ab apibus*, from the bees which fed on the grapes it was made of.

The way of making *muscadine* at Frontignac is as follows: they let the *muscadine* grapes grow half dry on the vine; and, as soon as they are gathered, they tread and press them immediately, and run up the liquor, without letting it stand and work in the vat; the lee occasioning its goodness. Phil. Transf. abr. vol. ii. p. 657.

MUSCÆ is used for officers of the popish inquisition, who feign themselves of the sect of the prisoners, in order to draw a confession of their opinion from them, and thereby betray them; there being persons placed to overhear their conversation. See MUSCA.

MUSCÆ *volitantes*, in *Optics*, dark irregular veins and spots, seeming to fly before the eyes of many people, especially on looking at bright objects, such as white paper, the sky-light, the candle, &c. These have often the appearance of cobwebs, sometimes that of smoke, dust, &c. The resemblance of many of these spots to flies has given them the name of *muscæ volitantes*, q. d. *flies flying about*.

This phenomenon is not easy to account for. Some will have its cause to lie in the aqueous humour; others in the retina. Mons. de la Hire's account of them is this: they are of two sorts; some permanent, which, in fixing the eye upon a point of an object, appear always fixed in the same situation to that point; others seem to fly about, and to change their situation, though the eye be fixed. The shapes of both sorts are changeable: the first sort are commonly like a dark spot upon a white ground; the second sort appear like the knots of a deal board; some parts of them being very clear, and surrounded with dark threads, they are also attended with long tufts of irregular shapes, which are bright in the middle, and terminated on each side by parallel black threads. On fixing the eye upon an object, they appear to descend gradually; especially after shaking the head suddenly.

The spots that appear fixed in respect to the axis of the eye, must, for that reason, be caused by some disorder in a correspondent part of the retina, or in some part of the vitreous humour lying pretty close to the retina. For an opacity of the coats or humours in any part remoter from the retina, by intercepting some part of the rays of every pencil, could only cause an uniform obscurity or faintness of light in every place of the retina, and not a total defect of it in any particular place. Hence Mr. de la Hire attributes the cause of these permanent spots to small drops of extravasated blood upon the retina.

But he finds it more difficult to account for the moving spots. When the rays of the sun are transmitted through a piece of bad glass, and fall upon white paper, the shadows of the little sands, veins, and irregularities in it, appear not unlike those spots. He therefore imagines the aqueous humour is sometimes troubled with some little motherly, ropy substance; some parts of which, by the figures of their little surfaces, or by refractive powers, different from the humour itself, may cast their distinct images upon the retina. He supposes them in the aqueous humour, rather than the vitreous; because of its greater fluidity for a freedom of descent, and because they will then appear to descend, as being situated before the pupil, or at least before the place of the intersection of the pencils. But if this heterogeneous matter be in the vitreous humour, it must be lighter than this humour, so that after a sudden shake of the head, it may first descend a little, and then ascend gradually, to cause the gradual apparent descent above mentioned.

These spots are observed to change their figures, sometimes in two or three hours, at other times not in two or three days; and to appear more numerous at one time than another. Dr. Smith's Optics in the Remarks, art. 27, *seq.*

We have an instance in the Philosophical Transactions, N° 384. of those fixed spots above mentioned. A woman, who, in looking with the left eye only, at three

short words in print, could see the extremes, but not the middlemost; and, in looking with the right eye only, at the middle between four short words, could see but three of them; one of the two middlemost being covered with a dark round spot; but in looking with both eyes she could see them all.

Pitcairn denies the cause of the *muscæ volitantes* to lie in the aqueous humour, and says it is owing to, and a sign of, an internal inflammation of the vessels of the retina. Heister thinks them owing to some obstruction of those vessels; and both these authors, and many others, think them forerunners of a gutta serena, or a cataract; and propose a cure by mercurials and decoctions of guaiacum. See Pitcairn's Elem. Medic. & Heister's Compend. Medic. Practic. Plempius has given a description of the *muscæ volitantes*, in his Ophthalmographia.

Dr. Porterfield, in the Medical Essays of Edinburgh, observes, that these spots may proceed from some little extravasations, verrucose swellings, or other defects in the retina, which, by intercepting the rays, will occasion a defect in the picture; and by consequence a similar and correspounding defect or spot in the object. He observes also, that these spots commonly vanish, or at least become less sensible, when the object is brought nearer the eye, and within the limits of distinct vision. For the rays which are now exactly united upon the retina, by being more crowded, have their force augmented; by which means a sensible impression is made upon the retina through these extravasations. Hence these spots are most sensible to those who have a small pupil, and especially to those who are short, or long-sighted. Hence also, in a presbytical eye, the spots which were formerly very sensible, become faint when the object is viewed through a convex-glass; for by means of this glass more rays enter the eye, which being united exactly at its bottom, must strike the retina strongly enough to make a sensible impression through these extravasations, which will render the spots obscure.

The learned doctor farther observes, that what has been said with respect to these spots, when occasioned by extravasations, or defects in the retina, will also hold when they are occasioned by a callosity, or any degree of paralysis or insensibility in some parts of the retina, by which the impulse received from the rays is made less sensible.

But, besides these defects in the retina, there is another cause which may give occasion to these spots, both in the *myopia* and *coloi fatuis*; and that is, certain small opaque marks in the cornea itself, or any where within the eye, which, by intercepting some of the rays, must occasion a defect in the picture, from which defect a kind of dark spot will be seen in the object. Thus, in the eye of a myops, if there be any opacity in the cornea, or within the eye which intercepts the rays B *b e*, C *c d*, and V L *o*, (*Tab.* V. *Optics*, *fig.* 81.) there will be a defect in the picture at *e*, *d*, and *o*; from whence also the external appearance will be defielent at the corresponding points E, D, and A; where by consequence, dark spots will be seen. For it is to be observed, that there is not one point in the picture which is formed by a plurality of rays which meet at the point, but every ray goes to a different point of the picture, both in myopical and presbytical eyes; and therefore, when any of the rays are intercepted, that part of the picture to which such rays belong will not be illuminated, which must occasion a corresponding *defect* in the appearance of the object. But in the perfect sight, where the rays which come from the several points of the object, are to refracted as to meet again at so many corresponding points in the retina, every point of the picture is formed by a cone of rays, whose base is the pupil; and therefore, though some of those rays be intercepted, yet no part of the picture will be darkened, and consequently no defect will be seen in the object from any such opacity in the cornea, or humours of the eye, unless that opacity be in the back part of the vitreous humour, where the pencil is narrow, and intercepts the whole pencil. This may be proved from the camera obscura, by sticking some small patches on the glass. These will not be perceived if the paper is placed at the due focal distance; but if the distance be greater or smaller, the spots will appear.

The doctor also observes, that these spots are not all of the same kind. He thinks that those which change not their place with respect to the axis of vision, proceed from some defect either in the retina or cornea, or in the vitreous and crystalline humours. As for those which are in constant motion, he supposes them to arise from some corpuscles floating in the aqueous humour.

Besides these dark spots, there is another kind often met with, more bright and luminous than the object itself before which they appear. These spots appear best by looking at distant bright objects, and are always of the same colour with the object. In the middle their colour is clear and strong, surrounded by a dark shady border. They are commonly accompanied with certain irregular veins, which proceed from each spot, and which as well as the spots themselves change their order and disposition. These veins are also of the same colour with the object, and being bright and luminous in the middle, are likewise terminated by a dark and obscure edge. These spots change their position with respect to the axes of vision, according as the eye is differently moved, being sometimes in the axis of vision itself, and at other times to the right or left of this same axis; but when the eye is kept fixed in the same direction, they, as well as the dark kind of spots first mentioned, commonly descend gradually.

As to the cause of these brighter spots and veins, it seems that, first, they must proceed from some corpuscles within the eye, which are at liberty to change their place, and which therefore must be supposed to float in the aqueous humour. Secondly, seeing these spots always descend when the eye is kept fixed, the corpuscles from which they arise must ascend; and are consequently lighter than the aqueous humour in which they swim. Thirdly, these spots being more bright and luminous than the object, they cannot be occasioned by any opaque corpuscles, which by intercepting the rays would cast a shade upon the retina. What therefore hath fairest for producing these brighter spots and veins, is some small, oily, diaphanous particles and filaments, which swim in the aqueous humour before the crystalline; for such, by their lightness, will ascend, when left to themselves; and by their greater refractive power, produce these luminous spots terminated by dark lines. That oily and sulphureous substances, though less denfe than water, have a stronger refractive power, is evident from the observations of Sir Isaac Newton. From which it follows, that the rays of light, which pass through these oily particles, will meet sooner behind the crystallines than the other rays; whence in a presbytical eye, the rays of light which come from the several points of the object will not converge to so many other points in the retina, but behind it, by which the picture in the retina will be rendered more dark and obscure; but the rays which pass through these oily grains, by having their refraction increased, will meet nearly at the retina, where they will form small luminous spots, surrounded with dark borders.

But we must here observe, that the same appearances happen to myopes; and this seems difficult to account for from this theory of the learned doctor.

Many medical authors have looked on the *muscæ volitantes* as forerunners of a cataract, or gutta serena. And we suppose it cannot be denied, that many who have fallen into those terrible disorders have had these appearances before their eyes; and hence they might have been taken for prognostics. But as it is no less certain, that many thousands have the same appearances, and yet preserve their sight very well to the last, there seems to be no great reason to be alarmed about them; and far less should people be running to quacks, and injuring their stomachs and constitutions by ill-judged physic on such occasions. St. Yves denies these appearances to be at all dangerous, and he thinks them owing to the separation of some parts of the retina from the choroid. However, as the disorder is troublesome and alarming to the patient, he advises purgatives from time to time, and nullepedes. We can say, from experience, that neither mercurials, nor sea-water, nor other purgatives, nor nullepedes, nor again Tunbridge or other chalybeate waters, have had any effect towards removing or diminishing these disorders. A greater dose of wine than usual has been known to increase it for a little time; and Plempius has made the like observation. We shall only add, that several of these flying appearances resemble little globules joined by threads, thus  and these globules appear in different numbers, and at different distances.

All authors agree, that these appearances change their figure, which is true, in some measure; but from our own observation we can say, that though they seem on a sudden looking to the sky, or other bright object, to vary in their figures; yet when they begin to descend, they return in one constant figure before we lose sight of them. On the whole it seems, this phenomenon is not yet fully accounted for. The vascular form of most of these appearances, their resemblances to small veins or arteries, make it difficult to conceive them floating in the humours of the eye; and, on the other hand, their seeming contortions, and change of figure, on suddenly looking up, or shaking the head, make it no less difficult to conceive them fixed and obstructed capillaries, as many authors suppose.

MUSCARI,

MUSCARI, in *Botany*. See *Muſk*, or *Grape* HYACINTH.

MUSCERDA, a name by which ſome authors have called mouſe-dung, a thing recommended by many as a purge for infants, and ſaid to be good in alopecias. Given in clyſters it is ſaid to be of ſervice in many diſorders of the bowels; and externally applied, to be of great uſe in condylomata of the anus.

MUSCICAPA, in *Ornithology*, a name by which Aldrovand and ſome others have called the STONE-*cracker*, making that bird, which is properly an ortanthe, one of the ſpecies of that genus of the fly-catchers.

MUSCICAPA. See FLY-*catcher*.

MUSCLE, *muſculus*, in *Anatomy*, a fleſhy, fibrous part of the body of an animal, deſtined to be the organ or inſtrument of motion.

The word is derived from the Greek μυς, or the Latin *mus*, a *mouſe*, on account of the reſemblance it is ſuppoſed to bear to a ſtunned mouſe. Dr. Douglas will have it from μυειν, *to ſhut*, or *contract*; that being the proper office of a *muſcle*.

The *muſcle* is a number of thin parallel plates; and is divided into a great number of faſciculi, or little *muſcles*, each incloſed in its proper membrane; from the internal ſurface whereof paſs an infinite number of tranſverſe filaments, which interſect the *muſcle* into ſeveral diſtinct areæ, filled with their reſpective faſciculi or fibres. See *Tab. Anat. Myolog. fig.* 1, 2, 3, 5, 7, &c.

A *muſcle* was uſually divided by the ancients into three parts, the *head*, the *tail*, and the *belly*. The *head* and *tail*, which are alſo called *tendons*, are the two extremes of the *muſcle*; whereof the firſt is fixed to the ſtable part, and the latter to the part intended to be moved. The *venter*, or *belly*, is the body of the *muſcle*, being a thick, fleſhy part, into which are inſerted arteries and nerves, and out of which iſſue veins and lymphæducts. However, the moderns, inſtead of the head and tail of a *muſcle*, uſe the terms of beginning or origin, and inſertion. Some of the moſt authors think it moſt proper to call one end of the *muſcle* the fixed point or fulcrum, and the other the moveable point. But Mr. Winſlow obſerves, that the beſt and moſt ſimple diviſion of a *muſcle* is into the body or fleſhy portion, which in ſome *muſcles* may be termed the belly, and the extremities, whether tendinous, aponeurotic, or fleſhy.

Theſe ſeveral parts of a *muſcle*, the belly and the tendons, are compoſed of the ſame fibres: their only difference conſiſts in this, that the fibres of the tendons are more cloſely and firmly bound together than thoſe of the belly, which are more looſe. Hence in the belly there is room for a ſufficient quantity of blood to give them an appearance of redneſs; and the whiteneſs of the tendons only proceeds from the blood's being in ſome meaſure excluded, by the tightneſs of their contexture. The diſference, then, between the belly and the tendons, ſeems to be the ſame as between a ſkein of thread, and a cord made of the ſame thread.

All the *muſcles* act by having their bellies inflated, or ſwelled; for by that means they are ſhortened, ſo as to draw, or pull the ſolid bodies to which they are to faſtened, according to the direction of their fibres. All the difficulty, then, in MUSCULAR *motion* is, to aſſign their fabric, and the cauſe of their ſwelling.

Every ſimple *muſcle*, then, conſiſts of one fleſhy belly, and two tendons; but it may be again divided into others, ſimilar, though leſs; and thoſe, again, into others, ſtill leſs, yet ſtill ſimilar to the great one; which diviſion may be carried on to a degree of ſubtilty that exceeds all imagination; though it is reaſonable to think it muſt have an end. That laſt, therefore, being ſimilar to the firſt, muſt, in like manner, have its belly and tendons; and this is what we ordinarily call a *muſcular fibre*; in an aſſemblage, or union, of ſeveral whereof, a *muſcle*, properly ſo called, conſiſts.

Some take the *muſcular fibres* to be productions of the arteries and veins, or the capillaries of thoſe veſſels inoſculated with, and continued to, each other; by the intumeſcence of whoſe contents, the extremities are drawn nearer each other, and, by conſequence, the bone to which the moveable part is fixed, approximated to the other. But that they are, in truth, neither venous nor arterious, nor lymphatic veſſels, is evident from the laſt obſervation. Whether they are veliculæ, or whether they only conſiſt of ſingle threads, may be ſtill a queſtion.

Dr. Boerhaave, from a conſideration that the nerves enter every *muſcle* along with its veins and arteries, and that there laying aſide their outer integument, they are ſo diſtributed through the whole body of the *muſcle*, as that no one point can be aſſigned wherein a part of them is not found; that thoſe nerves terminated here; and that in other parts of the body the extremities of the nerves are expanded, as it were, into membranes; concludes, that the *muſcular fibres* are nothing elſe but extremely ſlender expanſions of the nerves, ſtript of their integument, hollow within, and of the figure of a *muſcle*, and full of a ſpirit communicated by the nerve from its origin in the brain, or cerebellum, by the continual action of the heart. Or theſe fibres united are formed faſciculi, or bundles; which, again, have each their ſeveral membrane, wherein they are involved, and kept diſtinct from others. This membrane is extremely ſlender and porous within, and is full of oil (which is accumulated in time of reſt, and ſpent in motion), furniſhed by the arteries; and this oil, in conjunction with a ſmooth mucous juice, ſecreted by ſmall mucilaginous glands, interſperſed among theſe faſciculi, ſerves to lubricate the parts, and to preſerve the faſciculi from fretting on each other.

Now, beſides the nerves, there are arteries alſo carried into the *muſcles*, and thoſe in ſuch abundance, and of ſuch conſtexture, that a man might be inclined to think the whole body of the *muſcle* compoſed of them. Theſe are principally diſtributed among the faſciculi, and the membranes that ſeparate them, and, perhaps, alſo in the external ſurface of each fibrilla, where they terminate in reticular plexuſes, in little oily ſecretories, ſmall lymphatics, and, perhaps, in hollow fibrillæ, like nerves; which fibrillæ may again either terminate in the cavity of the nervous muſcular fibres, or make others like them. This, at leaſt, is clear, that every branch of an artery in the *muſcles* has its correſponding little vein, which, united to the other, increaſes its bulk; whence the blood-veſſels of the *muſcles* are alſo lymphatics.

Of two ſuch *muſcles* as have been deſcribed, ſaſtened in oppoſite ſituations to each other, conſiſt of the *muſcles*, or pairs of *muſcles*, we know of, conſiſt.

It has been already obſerved, that the tendon of a *muſcle* conſiſts of the ſame number of fibres with the *muſcle* itſelf; with this difference, that the cavities of the muſcular fibres diminiſhing, and loſing of their former diameter, they form one compact, hard, tough, dry, narrow body, which is but little vaſcular. From what has been ſaid, then, it appears, that the redneſs of a *muſcle* is owing to the blood; and its bulk to the fulneſs of the arteries, veins, oily cells, and lymphatics. Hence we ſee, why in old age, leanneſs, conſumptions, atrophies, conſtant feaſt, and hard labour, their redneſs, as well as bulk, are ſo diminiſhed; and yet in old age, leanneſs, &c. the motion remains. This may be effected when the *muſcles* have no redneſs left; as appears in inſects whoſe fleſh is not perceivable.

The fibres, faſciculi, arteries, and nerves, may be ſeparated from each other in a living or dead body, without breaking: they are always in a degree of tenſion, and are endued with a contractive force; ſo that when cut aſunder, the ends fly back from each other, and then they become ſhorter, their bulk is leſſened, and they contract themſelves into an undular kind of ſurface, and throw off their proper juices. Hence it appears, that they are always in a ſtate of violence, are ever oppoſing their elongation, and ever endeavouring to ſhorten themſelves, but more in a living body than in a dead one; and therefore they require antagoniſts.

If the brain be ſtrongly compreſſed, or have any violent contuſion; if it be ſuppurated, obſtructed, or torn, the voluntary action of all the *muſcles* immediately ceaſes, as well as all ſenſe and memory: however, the ſpontaneous action of the *muſcles* in the heart, lungs, the viſcera, and vital parts, remains. The ſame alterations being made in the cerebellum, the action of the heart, lungs, and life itſelf, ceaſes; when yet the vermicular motion continues a long time after in the ſtomach and inteſtines.

The nerve of any *muſcle* being compreſſed, tied up, corrupted, or cut, all the motion of that *muſcle*, both vital and voluntary, immediately ceaſes; and if a nervous trunk, ſending branches to ſeveral *muſcles*, be thus bound up, cut, &c. they are all affected in the ſame manner. The ſame things being done in any part of the ſpinal marrow, the action of all the *muſcles* whoſe nerves ariſe from the part affected, is deſtroyed; and the ſame thing being done to the artery which carries blood to one or more veſſels, the effect is the ſame.

The tendon of a *muſcle* in action does not undergo any ſenſible alteration; but the belly ſhortens, and becomes hard, pale, ſwoln, and protuberant; the tendons are approached nearer, and the more moveable part, faſtened to the tendon, is drawn towards the other leſs moveable; which action of a *muſcle* is called its *contraction*, which is much greater and ſtronger than that inherent contraction obſerved under the firſt phenomenon; and therefore is not natural, but ſuperadded. The tenſion of a *muſcle* not in action is ſtill the ſame; but the belly is ſofter, redder, laxer, longer, and flatter; and this ſtate of a *muſcle* is called its *relaxation*, though it is wholly owing to the contrary action of its antagoniſt; for that being fruſtrated, the contraction of the other continues, as not being balanced by the action of an antagoniſt.

If one antagoniſt remain at reſt while the other is in action,

tion, the member, in that caſe, will be bent; if both act at the ſame time, it will be fixed and immoveable; if neither act, it will be indifferent, and ready to be moved whither the leaſt exceſs ſhall carry it.

All which changes are performed in the ſmalleſt moment of time, and in the whole *muſcle* at once; ſo that they can paſs and repaſs reciprocally, without leaving any trace in the body behind them.

By injecting warm *water* into the artery of a quieſcent *muſcle*, even that of a dead carcaſe, its contraction is reſtored; and that long after death. The bulk of a *muſcle* is increaſed, rather than diminiſhed, by every experiment of its contraction. A limb being bent, by ſome external force, againſt the will, the *flexor muſcle* of that limb aſſumes the ſtate of contraction, as if acted by its proper motion, though not altogether ſo ſtrenuouſly.—The will remaining indifferent, all the voluntary *muſcles*, and all their veſſels, are equably full, and moved by the blood and ſpirits, equally conveyed to them, and that throughout the whole body at once.

For the application of this ſtructure of the *muſcles*, in accounting for the great phenomenon of *muſcular motion*, ſee MUSCULAR *motion*.

Mr. Winſlow, in his treatiſe on the *muſcles*, in his Expoſition anatomotique de la Structure du Corps humain, ſhews prodigious varieties in the actions of theſe organs of motion, which were never ſo much as hinted at before.

Dr. Walther us, after comparing the *muſcles* of the human body with the deſcriptions of them publiſhed by ſeveral authors, particularly by Mr. Winſlow, has made ſeveral accurate remarks on them, which may ſerve as a ſupplement to his Anatome teneriorum *muſculorum* recentita. Nov. Act. Erud. June 1733.

As to the muſcular fibres, or, which comes to the ſame, the faſciculi of muſcular fibres, they have not always the ſame ſituation with regard to each other, nor run in the ſame direction; but they ſometimes run parallel to themſelves and their tendons; and are ſometimes diſpoſed obliquely, both to their tendons and to each other, hence there ariſe two different kinds of *muſcles*; the one direct and parallel, which ſome call *ſimple muſcles*; the other inclined or oblique, called *compound muſcles*.

Under the firſt of theſe kinds are included ſeveral other ſpecies: for, firſt, either the fleſhy fibres run ſtrait from one extreme to the other, as in the *ſartorius*, &c. or they are turned into a circle, as in the *ſphincters* of the bladder and anus; or twiſted into a ſpiral, as in the *gaſtrocnemii*: and hence they come to be called *recti*, *orbiculares*, and *ſpirales*.

The ſecond kind alſo includes various ſpecies, according to the various angles which the oblique fibres make with the tendons; ſome inclining equally to each tendon, ſo as to form a rhombus, or acute-angled parallelogram, with them: whence the *muſcles* are called *rhomboidales*; others, ariſing from two parallel tendons, are inſerted obliquely into one common tendon, as in the biceps of the hand; laſtly, others, ariſing from the periphery of the circle, concur in a centre, and form *muſcles* called *radiati*.

There are divers others ſpecies and diviſions of *muſcles*. Some authors diſtinguiſh them into *muſcles of voluntary*, and of *involuntary* or *neceſſary motion*.

MUSCLES *of voluntary* or *neceſſary motion* have their contracting or extending powers within themſelves, and have no antagoniſt: ſuch are the heart and lungs ſuppoſed to be.

MUSCLES *of involuntary motion*, which we more peculiarly denominate *muſcles*, and which are thoſe we have here chiefly regard to, have each of them their antagoniſt *muſcles*, which act alternately in a contrary direction; the one being ſtretched and extended, while the other is contracted, at the inſtance of the will.

The *muſcles* have alſo different names from their different actions, ſituations, forms, &c. Thoſe which ſerve to move the ſame members contrary ways, are called *antagoniſts*; and thoſe that concur to the ſame action, *fellows* or *pairs*.

MUSCLES, *accelerators*. See ACCELERATOR.

MUSCLES, *digaſtric*, are thoſe which have two bellies. *Trigaſtrici*, thoſe with three.

MUSCLES, *ſphincter*, are thoſe deſtined to ſhut ſeveral apertures and paſſages in the body, as the *muſcle* at the neck of the bladder, and that of the anus; which have the ſame effect with the ſtring of a purſe, to cloſe thoſe parts.

Some *muſcles* have two or three heads, called *biceps* and *triceps*.

We call *elevators* thoſe which lift up or raiſe the parts; and *depreſſors*, thoſe which move them downwards.

Flexors, thoſe which bend them; *extenſors*, thoſe which ſtretch them out; *adductors*, thoſe which move the parts inwards; *abductors*, thoſe which move them outwards; and *rotators*, thoſe which move them round.

Muſcles have alſo different names, from their different figure; ſome reſembling a bat, and ſome a lizard: ſome are triangular, others ſquare, other ſcalenous, others pentagonal, others pyramidal, round, &c. whence the names of *deltoides*, *rhomboides*, *ſcalenus*, *trapezius*, &c.

Anatomiſts are not agreed on the number of *muſcles* in the human body: ſome reckon five hundred and twenty-nine; ſome four hundred and forty-ſix; and others only four hundred and thirty-five. The calculus, according to theſe laſt, is as follows: two of the forehead, two of the occiput, ſix of the eyelids, twelve of the eyes, ſeven of the noſe, eight of the external ear, four of the internal ear, thirteen of the lips, eight of the tongue, four of the palate, fourteen of the larynx, ſeven of the pharynx, ten of the os hyoides, twelve of the under-jaw, fourteen of the head, eight of the neck, eight of the omoplates, eighteen of the arms, twelve of the elbows, eight of the radii, twelve of the carpi, forty-eight of the fingers, fifty-ſeven of uſe in reſpiration, ſix of the loins, ten of the abdomen, two of the teſticles, one of the bladder, four of the penis, four of the anus, thirty of the thighs, twenty-two of the legs, eighteen of the feet, forty-four of the toes.

The following table of the names and offices of the ſeveral *muſcles* in the body, is taken from Dr. Keil.

Frontales ſerve to pull the ſkin of the forehead upwards.

Occipitales pull the ſkin of the hind-head upwards.

Attollens, *Deprimens* } *auricularum.*

Intrinſus malleoli diſtends the tympanum.

Externus malleoli relaxes the tympanum.

Obliquus malleoli.

Muſculus ſtapedis moves the ſtirrup.

Curvagator ſupercilii.

Rectus palpebræ ſuperioris lifts up the upper eye-lid.

Orbicularis palpebrarum ſhuts both the eye-lids.

Attollens, *Deprimens*, *Abductor*, *Adductor* } *oculorum.*

Obliquus major pulls the eye forwards, and obliquely downwards.

Obliquus minor pulls the eye forwards, and obliquely upwards.

Attollens, *Dilatans*, *Deprimens* } *nares.*

Inciſivus pulls the upper lip upwards.

Triangularis pulls it downwards.

Caninus, *Elevator labii inferioris* } pull the lower lip upwards.

Quadratus pulls it downwards.

Zygomaticus draws both lips obliquely to either ſide.

Orbicularis draws both lips together.

Buccinator thruſts the meat between our teeth.

Temporalis, *Maſſeter* } pull the jaw upwards.

Pterygoidæus internus draws the jaw to either ſide.

Pterygoidæus externus draws the jaw forwards.

Quadratus pulls the jaw and the cheek downwards.

Digaſtricus pulls the jaw downwards.

Periſtaphylinus internus pulls the uvula forwards.

Periſtaphylinus externus pulls the uvula backwards.

Styloglaſſus draws the tongue upwards.

Genioglaſſus thruſts it out of the mouth.

Ceratoglaſſus pulls it into the mouth.

Genioſyoidæus pulls the os hyoides and tongue upwards and forwards.

Sternohyoidæus pulls the os hyoides downwards.

Myolohyoidæus pulls it obliquely upwards.

Coracohyoidæus pulls it obliquely downwards.

Stylohyoidæus pulls it to either ſide, and ſomewhat upwards.

Stylopharingæus pulleth up and dilateth the pharynx.

Oſophagæus ſtraitens the pharynx.

Sternothyroidæus pulls the thyroides downwards.

Hyothyroidæus pulls the thyroides upwards.

Cricothyroidæus.

Cricoarytænoidæus poſticus.

Cricoarytænoidæus lateralis.

Thyroarytænoidæus dilates the glottis.

Arytænoidæus contracts the glottis.

Splenius, *Complexus* } move the head backwards.

Rectus major, *Rectus minor* } noil the head backwards.

Obliquus inferior, *Obliquus ſuperior* } perform the ſemicircular motion of the head.

Maſtoidæus

Rectus internus major } nod the head forwards.
Rectus internus minor }
Rectus lateralis nods the head on one side.
Intercostales interni & externi } pull the ribs upwards in inspiration.
Subclavius }
Serratus anticus major }
Serratus posticus superior }
Triangularis }
Serratus posticus inferior } make the motion of the ribs downwards, in expiration, the former.
Sacrolumbaris }
Diaphragma, used in inspiration and expiration.
Obliquus externus } compress the parts contained in the lower belly, assist the motion of the ribs downwards in expiration, and help to bend the vertebræ of the loins forwards.
Obliquus internus }
Transversalis }
Rectus }
Pyramidalis }
Longissimus dorsi moves the body erect.
Transversalis dorsi moves the body obliquely backwards.
Interspinalis draws the acute processes near one another.
Quadratus lumborum draws the vertebræ of the loins to one side.
Longus } bend the vertebræ of the neck.
Scalenus }
Psoas parvus helps to bend the vertebræ of the loins.
Cremaster draws up the testicles in the act of generation.
Erectores penis.
Transversales penis.
Accelerantes urinæ.
Erectores clitoridis.
Sphincter vesicæ contracts the neck of the bladder, that the urine may not run continually.
Levatores ani draw up the anus.
Sphincter ani shuts the anus.
Serratus anticus minor draws the shoulder-blade forwards.
Trapezius moves it upwards, backwards, and downwards.
Rhomboides pulls it backwards.
Levator scapulæ pulls the shoulder-blade upwards.
Deltoides }
Supra-spinatus } lift the arm upwards.
Coracobrachialis }
Teres major }
Latissimus dorsi } pull the arm downwards.
Pectoralis moves the arm forwards.
Infra-spinatus }
Transversalis } draw the arm backwards.
Subscapularis }
Biceps } bend the fore-arm.
Brachiæus internus }
Longus }
Brevis } extend the fore-arm.
Brachiæus externus }
Anconæus }
Rotundus } perform the motion of pronation, or turn
Quadratus } the palm of the hand downwards.
Longus } perform the motion of supination, or turn the
Brevis } palm of the hand upwards.
Cubitæus internus } bend the wrist.
Radiæus internus }
Cubitæus externus } extend the wrist.
Radiæus externus }
Palmaris helps the hand to grasp any thing closely.
Palmaris brevis makes the palm of the hand concave.
Sublimis } bend the fingers.
Profundus }
Extensor digitorum communis.
Lumbricales assist in bending the first joint of the fingers.
Interossei interni draw the fingers to the thumb.
Interossei externi draw the fingers from the thumb.
Flexor pollicis longus.
Flexor pollicis brevis.
Extensor primi }
——— *secundi* } *internodii pollicis.*
——— *tertii* }
Abductor draws the thumb from the fingers.
Adductor draws the thumb to the fingers.
Abductor indicis.
Extensor indicis.
Hypothenar draws the little finger from the rest.
Extensor carpi ulnaris.
Psoas }
Iliacus } bend the thigh.
Pectinæus }
Glutæus major }
Glutæus medius } extend the thigh.
Glutæus minor }
Triceps pulls the thigh inwards.
Pyriformis }
Gemini } move the thigh outwards.
Quadratus }
Obturatus internus } help to move the thigh obliquely and circularly.
Obturator externus }
Semitendinosus }
Semimembranosus } bend the leg.
Biceps }
Gracilis }
Rectus }
Vastus externus } extend the leg.
Vastus internus }
Cruræus }
Sartorius makes the legs cross one another.
Popliteus turns the legs somewhat inwards.
Membranosus turns it a little outwards.
Tibialis anticus } bend the foot.
Peronæus anticus }
Gastrocnemii }
Soleus } extend the foot.
Plantaris }
Tibialis posticus moves the foot inwards.
Peronæus posticus moves the foot outwards.
Profundus }
Sublimis } bend the four lesser toes.
Lumbricalis }
Longus }
Brevis } extend the four lesser toes.
Flexor pollicis.
Extensor pollicis.
Thenar draws the great toe from the rest.
Antithenar draws it to the rest.
Flexor pollicis longus.
——— *brevis.*
Abductor minimi digiti } draw the toes toward the great
Interossei externi } toe.
Interossei externi draw them from the great toe.
Transversalis brings all the toes close to one another.

MUSCLES, *insertion and force of the.* The all-wise Author of nature has furnished animals with limbs, moveable about the joints by means of muscular cords, inserted near the joint or center of motion; the great wisdom of which contrivance will appear, from supposing the insertion to be at E (*Tab.* V. *Mechanics, fig.* 82.) near the wrist B, the *muscle* D E being either loose and separate from the bones D A B, or bound down to it by some ligament or fascia R; in either of which cases the bone A B cannot be turned up quite to the situation A B, unless the *muscle* D E be contracted or shortened to D M, which would not only be troublesome but even impossible. It would be troublesome because the breadth and thickness of the arm would be vastly increased, so as to become as big as the belly of an animal. On the other hand, the structure of a *muscle* being such that it cannot be contracted but a little, seldom above two or three fingers-breadth; such an insertion as that at E, which requires a contraction of above a foot and a half, would be altogether impossible. Therefore, in fact, we find, the *muscles* inserted near the center of motion, as at I, *fig.* 83. In order to calculate the force of any *muscle*, we are to consider the bones as levers; and then the power or force of the *muscle* will be always to the resistance or weight it is capable of raising, as the greater distance of the weight from the center of motion is to the lesser distance of the power. Hence, it being found by experiments, that a robust young man is able to suspend a weight R (ibid. *fig.* 83.) equal to twenty-eight pounds, when the arm is extended in a supine and horizontal situation, we have this proportion, viz. the force of the *muscle* I D is to the weight R, = 28 lb, as the distance B C is to the distance I C. But it is found, that B C, the length of the cubit and hand, is more than twenty times greater than I C, the distance of the *muscle* from the center of motion. Therefore the force of the *muscle* I D must be more than twenty times greater than the weight R, or more than $28 \times 20 = 560$ lb.

Again, to find the force which the biceps and brachiæus *muscles* exert, when the humerus E A (ibid. *fig.* 84.) is perpendicular to the horizon, we are first to consider what weight a man is capable of sustaining in this posture, viz. R = 35 lb, and next the quantity of the distances C B, C I, which in this case are as 16 to 1. Therefore the force of these *muscles* is to the weight R = 35 lb, as the distance C B = 16 is to the distance I C = 1; or the force is equal to 560, as before.

But what appears most wonderful, is the force of the *muscles* that move the lower jaw; which, when taken altogether, do not in a man exceed the weight of 1 lb, and yet exert a force equal to 534 lb; and in mastiff dogs, wolves, bears, lions, &c. their force is vastly superior, so as to break large bones, as they practise daily in their feeding. See Borelli de Motu Animalium; and, for an abstract, Desaguliers Exp. Phil. vol. 2. p. 153, &c.

See MECHANICS.

The *muscles* in fishes are not placed lancellation, or one upon another in a longitudinal direction; but they are generally laid either transversely or somewhat obliquely one behind another, from the anterior part of the body to the origin of the tail. This structure is best seen in the spinose fishes.

These *muscles* of the spinose fishes may be conveniently divided, according to their situation, into the dorsal, pectoral, and ventral. After these, the inferior ones of that part of the body near the tail are to have their place; and, finally, the cephalic, or those of the parts about the head.

The dorsal *muscles* have an interstice in the middle of the length of the back, or are separated longitudinally from one another, and are terminated in the sides over-against the spina dorsalis. The pectoral and ventral *muscles* take their origin from the bans of the ribs, and they meet in the middle of the breast and belly. The *muscles* of the lower part of the body arise along the spina dorsi, and meet one another in the bottom of the belly. The cephalic *muscles* serve to the moving the eyes and the jaws, and are principally four: one is placed on each side under the eyes, and one on each side in the lower jaw. The two former are called the hypophthalmic *muscles*, and the two others the maxillary *muscles*; they are most evident in the gadi, &c.

Muscles *of vegetables.* The *muscles* in animal bodies have been the subject of numerous dissertations; but those in vegetables have been less regarded. Mr. Tournefort, however, has plainly proved, that many of the vessels of plants become in the drying fibres capable of tension; that in many plants there are great numbers of these fibres which have all the same direction, and always act all together, and can only shorten or contract themselves in one particular direction; wherefore the parts composed of these fibres are very properly compared to the *muscles* of animals. By the word *muscle* we understand a part composed of fibres so determinately arranged, that by their contraction they can only move the part in some certain and determinate manner; and in this, which seems the received sense of the word, there are many instances in which it may be applied to parts of plants, with the strictest justice.

All the pods of the leguminous plants, as peafe, &c. are composed each of two valves, more or less convex on the outside; these are placed evenly upon one another, and fastened together by means of a great number of very fine veffels; they are fastened much more firmly together at the back, than at the fore-rim; and the large veffels which carry nourishment both to the valves and feeds, are lodged there, and fend many ramifications to one and the other of the valves of the pod.

Each valve is formed of two ranges of fibres; the exterior arrangement is formed into a fort of net-work, and the threads which compofe it iffue from the back of the pod, and are propagated longitudinally and fomewhat obliquely through the furface of the valve, and finally terminate at the edge of the fore-rim of the pod, after they have entered into the fleshy part, with the net-like plexus of veffels, of which they make frequent anaftomofes.

The interior plan or arrangement of fibres croffes the exterior, in the fame manner as the interior intercoftal *muscles* in the human body crofs the exterior; and thefe form the inner membrane of the pod: thefe fibres arife like the others from the back of the pod, and run obliquely to the edge. A neceffary confequence of this ftructure is, that the arrangement of exterior fibres muft become dry before the others, as muft alfo the fleshy fubftance in which they lie; and the confequence of this is, that they muft contract and draw the edge of the valve to which they belong at once upward and outward, and endeavour to feparate it from the edge of the other valve, drawing with it the anterior arrangement of fibres; this therefore pulls open the pod, and the air, which is very hot at the feason when the feeds of thefe plants ripen, infinuating itfelf into the interftices of the internal arrangement of fibres which are expofed to it by the opening of the pod, foon acts upon them, and they begin to contract in their turn. Thefe fibres were once the veffels which conveyed the nutritive juice to the pods and feeds; but when that ufe as no longer neceffary for them, and when no more juices afcend, after the feeds have arrived at their deftined fize, they foon fhrink up, and no more perform the office of veffels, but become mere fibres. As thefe do not all dry up, and fuffer this change together, but neceffarily it happens firft to thofe which are fituated at the greateft diftance from the pedicle, and confequently thofe are the firft of the interior fibres which act by fhortening themfelves; this therefore begins at the extremity of the pod, and is continued up to the pedicle, and the effect is, that as thefe interior fibres are ftronger and more numerous than the exterior, which are at this time as far fhortened as they are capable of, they now draw backwards and inwards the lips of the edge of the pod towards the back. When the warm air acts upon thefe fibres to dry and contract them, it draws nearly equally at both their ends; and therefore, if the two arrangements of fibres were regularly tranfverfe, each valve of the pod muft be drawn by this action into a fort of tube, or pipe; but as they are placed in an oblique direction, and parallel to one another, the natural effect of thefe contraction muft be the drawing the valve into a fpiral form, which we fee is exactly the cafe. The lines which form the rim of each valve can make no refiftance to this contraction, becaufe they are fo dried up by the warm air, and want of juices, that they may be crumbled to powder between the fingers, and eafily break in any part with the fmalleft force. This clafs of plants gives numerous inftances of this fort of *muscles* in vegetables, and they are more obvious than moft others, being not only common in the hedges, but cultivated in gardens for the ufe of the kitchen, &c.—The ingenious author of the fyftem gives many other inftances in other plants. Mem. Acad. Par. 1708.

Muscles, in *lithology*, the Engliſh name of the *mytulus*, or *mytilus*, a genus of fhell-fifh, or, in the Linnæan fyftem, of the *vermes* clafs of worms; the characters of which are thefe: it is a bivalve fhell, of an oblong form, ending in a point, and having its two extremities equal. It is fometimes fmooth, fometimes rough; in fome fpecies flat, in other clute; and in fome has the beak cleft. The *tellina* and *pinna marina*, of each of which there are feveral fpecies, are property of this genus.

The characters of the *mytilus*, according to Linnæus, are thefe; that its animal is an *oyster*; that it is bivalve, and often affixed to fome fubftance by a beard; and that its hinge is without a tooth, marked by a longitudinal hollow line. He reckons twenty-three fpecies.

The three words of *mytulus*, *muscarus*, and *tellina*, may however be made of great ufe in the fubdiftinctions of the genus into certain feries.

In this fenfe, the word *mytulus* may expreſs all the large *muscles*, fuch as the *pinna marina*, and other *mufcli*, which are remarkably much elevated in their fhape, and have pointed beaks. The word *muscarus* may be ufed to fignify fuch *muscles* as are fmaller and more flat; and *tellina* to expreſs, as it ufually does with authors, a bivalve fhell of the *muscle* kind, but thinner and tenderer, and of an oblong figure, but not pointed.

The hinge of thefe fhells is not in the centre of the fhells, but towards one end, and they have ufually a kind of little beak at that part.

The *tellinæ* are attached to the fhell by two ligaments; the *muscles* only by one.

The largeft kind of *mytuli*, we know, is the PINNA *marina*, made a diftinct genus by Linnæus; of which fhell we have three kinds; one larger than the reſt, which is red within; this often produces pearls, but they are nearly of the fame reddifh colour with the lining of the fhell. There have been found fhells of this fpecies fo large as that the pair have weighed fifteen pounds. The fmall *pinnæ*, and the rough echinated *pinnæ* have their fhells thicker near the edge where they open, than at the cardo. Thefe *pinnæ marinæ* have a fort of filaments iffuing from the body of the fifh, and faftening it to ftones, or any other fubftances. Thefe the ancients called *byffus*, and wrought it into gloves and other things of that kind; and in fome places it is to this day put to the fame ufe. The common *muscles* have the fame property of forming thefe threads; and Lifter has hence called them *byffiferæ*. The filk of thefe common *muscles* is greatly inferior to that of the *pinna marina* in fineneſs and beauty. The *muscles* hold themfelves in the fame place, by means of their threads. The *pinna marina* ſticks its fharp end into the mud or fand, and all the reſt of the fhell remains at liberty to open in the water. Its filaments, which are propagated from the middle of its body, ſerve to draw up the mud and fand about it, on occafion, to defend it againſt the motion of the water in tempefts.

The fpecies of *muscles*, moſt known at prefent, are thirteen: of thofe known in cabinets under the name of *pinna marina*, we have eight: of thofe *mytuli*, which have a more clate figure, and equilateral, we have fix. See *Tab. Shells*, N° 30. Of the *tellinæ*, which are oblong and flat fhells, with equal extremities, we have ten; but of thofe which have the two ends unlike we have fourteen. Hift. Nat. Eclair. p. 226.

The common fex *muscles*, or *mytili edules* of Linnæus, diſtinguiſhed by a ſtrong fhell, ſlightly indented on one fide and angulated on the other; the end near the hinge being pointed, the other rounded, is of a deep blue colour, when the epidermis is taken off. Thefe are found in immenſe beds both in deep water and where

low water mark. They afford a rich food, but noxious to many constitutions.

Those who have eat *muscles* have sometimes, but very rarely, been affected with erysipelatous inflammations, cutaneous eruptions, insupportable itching all over the body, great restlessness and agitation; and though these complaints are easily removed, by oil, milk, and emetics, and have seldom or never proved mortal, yet they have an alarming aspect, and make the patient suffer grievously. Some authors have pretended, that these noxious effects never take place but between the vernal and autumnal equinox; and M. Beunie, physician at Antwerp, in a memoir on this subject, seems inclined to adopt this opinion; for he recommends abstinence from *muscles* during the months of May, June, July, and August. The cause of these noxious effects in the *muscle* is, according to this author, altogether accidental. They are occasioned, he says, by a kind of *stella marina*, a little sea insect, pretty common about the mouth of the Scheld, which sometimes lodges itself in the *muscle*, in quest of food, and whose sperm is so caustic and inflammatory, that, even when applied outwardly to the skin, it produces itching and swellings, that are painful and disagreeable in a high degree. The itching occasioned by touching the spawn of the *stella marina* is removed by vinegar; and this known fact induced Dr. Beunie to prescribe the internal use of vinegar, after bleeding, evacuations, and emetics. His method consists in recommending a large quantity of refreshing beverage, and, every hour, three ounces of vinegar diluted in water. This remedy, however, seems rather to confirm the opinion of those who impute the disorder in question to an unperceived commencement of putrefaction in the *muscle*; as vinegar is known to be a powerful antiseptic, and there is no sort of putrefaction more noxious and offensive than that of fish. Mem. de l'Academie Imp. & Roy. des Scienc. & Belles Lettres de Bruxelles, &c. vol. i. mem. 8.

The common *sea muscle* has, from its being always found fastened to the rocks, been supposed by many wholly incapable of progressive motion; but this is an erroneous opinion. It is a common practice in France at such seasons of the year as do not afford sun enough to make salt, to throw the common *sea muscles*, which the fishermen catch about the coasts, into the brine pits. They have an opinion that this renders their flesh the more tender and delicate, as the rain which falls at these seasons makes the water of the pits much less salt than the common sea water. The *muscles* are on this occasion thrown carelessly into several different parts of the pit; not, at whatever distances they have been thrown in, the fishermen, when they go to take them out, always find them in a cluster together; and as there is no current of water in these places, nor any other power of motion which can have brought the *muscles* together, it seems very evident that they must have moved from the places where they were at first, to have met thus together. This progressive motion is wholly performed by means of what we call the tongue of the *muscle* from its shape; but, from its use in this case, appears rather to merit the name of a leg, or an arm, as by laying hold of any distant substance, and then forcibly contracting itself again, it draws along the whole body of the fish; the same part, when it has moored the animal to a proper place, serves also to fix it there, being the organ by which it spins the thread which we call its beard, by which it is held to a rock, or to any other *muscle*. The motion of the *muscles*, by means of this part, is just the same with that of a man laid flat on his belly, who would draw himself along by laying hold of any thing with one hand, and then drawing himself to it. Mem. Acad. Par. 1701.

Muscles are well known to have a power of fastening themselves very firmly either to stones, or to one another's shells, in a very strong and firm manner; but the method of doing this was not well understood, till the observations of the accurate Mr. Reaumur explained it.

Every one who opens and examines a common *muscle* will find, that in the middle of the fish there is placed a little blackish or brownish body resembling a tongue; this in large *muscles* is near half an inch long, and a little more than a fixth at an inch in breadth, and is narrower at the origin than at the extremity; from the root of this tongue, or that part of it which is fastened to the body of the fish, there are produced a great number of threads, which when traced to any solid substance hold the *muscle* firmly to its places: these threads are usually from an inch to two inches in length, and in thickness from that of a hair to that of a hog's bristle. They issue out of the flesh in that part where it naturally opens, and fix themselves to any thing that lies in their way, to stones, to fragments of shells, or, which is the most common case, to the shells of other *muscles*; whence it happens, that there are usually such large parcels of *muscles* found together.

These threads are expanded on every side, and are usually very numerous; a hundred and fifty have been found issuing from one shell; they serve the office of so many cables, and each pulling in its proper direction, they keep the *muscle* fixed against any force that can be offered, from whatever part it come. The filaments are well known to all who eat *muscles*, who ever carefully separate them under the name of the beard; and Mr. Reaumur has found, that while the animal is living in the sea, if they are all torn away by any accident, the creature has a power of substituting others in their room; he found that if a quantity of *muscles* were detached from one another, and put into a vessel of any kind, and in that plunged into the sea, they in a little time there fastened themselves both to the sides of the vessel and to one another's shells, the extremity of each thread formed in this case to serve in the manner of a hand to seize upon any thing that it would fix to, and the other part, which was slenderer and smaller, to do the office of an arm in conducting it.

To know the manner of the *muscle's* performing this operation, this diligent observer put some *muscles* into a vessel in his chamber, and covered them with sea water; he there saw that they soon began to open their shells, and each put forth that little body before described by its resemblance to a tongue, and at the root of which these threads grow; they extended and shortened this part several times, and thrust it out every way, often giving it not less than two inches in length, and trying before, behind, and on every side with it, what were the proper places to fix their threads at: at the end of these trials they let it remain fixed for some time on the spot which they chose for that purpose, and then drawing it back into the shell with great quickness, it was easy to see that they were then fastened by one of these threads to the spot where it had before touched and remained fixed for a few minutes; and in repeating this workmanship the threads are increased in number one at every time, and being fixed in different places they fasten the fish as well against any common force.

The several threads were found to be very different from one another; the new formed ones being ever whiter, more glossy, and more transparent than the others; and it appeared on a close examination, that it was not, as might have been most naturally supposed, the effect of the tongue to convey the old threads one by one to the new places where they were now to be fixed, but that these in reality were now become useless; and that every thread we see now formed is a new one made at this time; and, in fine, that nature has given to some sea-fishes, as well as to many land insects, a power of spinning these threads for their necessary uses: and that *muscles* and the like fish are under water, what caterpillars and spiders are at land. To be well assured of this, however, Mr. Reaumur cut off all the beard or old threads of a *muscle* as close as he could, without injuring the part, and a proof of the opinion of their spinning new ones at pleasure was now brought to this easy trial, whether these *muscles*, so deprived of their old ones, could fix themselves as soon as others which were possessed of theirs, and could throw out their threads to as considerable distances. The experiment proved the truth of the conjecture, for those whose beards or old threads were cut off, fixed themselves as soon as those in which they were left, and spread their threads to as great a distance every way.

When the mechanism of this manufacture was thus understood, it became a natural desire to examine into the nature of the part by which it was performed: this has hitherto been mentioned under the name of the tongue, from its shape; but it is truly the arm of the fish, and whenever it happens to be loosened from its company, or fixed in a wrong place, it serves the animal to drag its whole body shell and all along, and to perform in several motions. It fixes itself to some solid body, and then strongly contracting its length, the whole fish must necessarily follow it, and be pulled forward to the place where it is fixed. This is an use, however, that this part is so rarely put to, that it is not properly to be esteemed a leg or an arm, for this, but, according to its more frequent employment, may much better be denominated the organ by which the threads are spun.

Though this body is for in the manner of a tongue for the greater part of its length, it is however, rounded or cylindric about the base or insertion, and it is much smaller there than in any other part: there are several muscular ligaments fastened to it about the root or base, which hold it firmly against the middle of the base of the shell: of these ligaments there are four, which are particularly observable, and which serve to move the body in any direction. There runs all along this body a slit or crack, which pierces very deeply into its substance,

and

and divides it as it were into two longitudinal sections: this is properly a canal, and along this is thrown the liquor which serves to form the threads; and it is in this canal or slit that these threads are moulded into their form. Externally, this appears only a small crack or slit, because the two fleshy sections of the parts almost meet and cover it, but it is rounded and deep within, and is surrounded with circular fibres. This canal is carried regularly on from the tip of the tongue, as it is called, to its base, where it becomes cylindric; the cylinder in this part being no other than a close tube or pipe, in which this open canal terminates. The cylindric tube contains a round oblong body, of the nature of the threads, except that it is much larger; and from the extremity of this all the threads are produced, this serving as a great cable to which all the other little cordages dispersed towards different parts are fixed. The tube or pipe in which this large thread is lodged, seems the reservoir of the liquor of which the other threads are formed; all its internal surface being furnished with glands for its secretion. Mem. Acad. Par. 1711.

The *muscle*, like many other sea fishes, abounds in this liquor: and if at any time a finger touches the base of this spinning organ, it draws away with it a viscous liquor in form of several threads, like those of the caterpillar, spider, and other spinning land animals. The threads fix themselves with equal ease to the most smooth and glossy, as to rougher bodies: if the *muscles* are kept in glass jars of sea water, they as firmly fasten themselves to the glass as to any other body.

Muscles, be they ever so young, have this property of spinning; and by this means they fasten themselves in vast numbers to any thing which they find in the sea. Mr. Reaumur has seen them when as small as musseleeds, spin plentifully, though their threads, proportioned to their own weight, are much finer and smaller than those of larger *muscles*.

It is a question yet undetermined whether the *muscle* has a power of breaking, or otherwise getting rid of its threads, in order to its removing from the place where it is once fixed; but it appears probable that they have not, and that they must remain where they have once fastened themselves, though their destruction be the consequence of it. Mr. Reaumur tried this experiment in his jars; when they had well fixed themselves to the sides of them, he poured off part of the salt water, so that it became the interest of the fish to leave their hold and go lower down, but they seemed to have no power to effect this. Mem. Acad. Par. 1711.

The common *muscle* affords the curious observer a very pleasing object of examination by the microscope. The transparent membrane, which immediately appears on opening the shell, shews the circulation of the blood for a long time together, through an amazing number of vessels. And Mr. Leewenhoek, in several which he dissected, discovered numbers of eggs and embryo *muscles* in the ovarium, appearing as plainly as if he had seen them by the naked eye, and all lying with their sharp ends fastened to the fixing of vessels by which they received nourishment. The minute eggs, or embryos, are by the parent placed in due order, and in a very close arrangement on the outside of the shell, where, by means of a gluey matter, they adhere very fast, and continually increase in size and strength, till becoming *perfect muscles* they fall off and shift for themselves, leaving the holes where they were placed behind them. Baker's Microscope. p. 242.

This abundance of *muscle* shells very plainly shew, when examined by the microscope, and sometimes they are to the number of two or three thousand on one shell; but it is not certain that these have been all fixed there by the *muscle* within; for these fish usually lying in great numbers near one another, the embryos of one are often affixed to the shell of another. The fringed edge of the *muscle*, which Mr. Leewenhoek calls the beard, has in every the minutest part of it such variety of motions as is inconceivable; for being composed of longish fibres, each fibre has on both sides a vast many moving particles.

MUSCLE, *horse*, a common English name for the fresh-water *muscle*, a large species of shell fish, very common in our fish ponds. Mr. Mery, of the Paris Academy, has been at the pains of making a number of curious observations on this animal. He observes that they are all hermaphrodites; and that, by a strange and before unheard-of method of generation, each individual is of itself capable of propagating its species, and annually does it without the intercourse of any other. This is extremely singular, because though we know many animals which are hermaphrodites, or in which each individual contains the parts of both sexes, yet in snails, earth-worms, and all the rest of these kinds, there is always a congress of two animals for the propagation of the species.

The shell of the fresh-water *muscle* is composed of several laminæ or beds of matter, in the manner of many of the sea-shells, and is lined within with an extremely delicate and thin membrane, which is not easily distinguished while the shell is recent, but when it becomes dry it usually separates from it and peels wholly off. This fish opens and shuts its shell by a very strong hinge, assisted by two strong muscles; the contraction of these shuts the shells firmly together, and a powerful spring or force in the animal opens them at pleasure. The part which performs this office is distinctly seen on the back of the fish, and is an inch and half long, and about a sixth of an inch broad. Mem. Acad. Par. 1710.

MUSCOVITE *Bible*. See BIBLE.

MUSCOVITE *coinage*. See COINAGE.

MUSCOVITE *ewer*. See COINS.

MUSCOVITE *glass*. See MICA.

MUSCOVITE *mariners*. See MEASURE.

MUSCULAR, or MUSCULOUS, something that relates to the muscles, or that partakes of the nature thereof. See MUSCLE.

In which sense we say, *muscular fibre*, *muscular coat*, *muscular flesh*, *muscular veins*, *muscular arteries*, &c.

MUSCULAR *arteries*, two *arteries* proceeding from the subclavians, and distributed among the hind-muscles of the neck. The same denomination is also given by some to certain arteries of the loins: these are divided into *upper* and *under*. *Musculares superiores*, the *upper-muscular*, proceed from the large artery, and lose themselves in the flesh.

The *under muscular*, *musculares inferiores*, are branches of the inner iliac arteries.

MUSCULAR, *muscular*, is also a name given to two arteries of the thigh, the one called the *external muscular*, as being distributed among the inner muscles of the thigh; the other the *external muscular*, because it proceeds to the outer part.

MUSCULAR *fibres* are the fine threads, or fibres, whereof the body of muscles is composed. See FIBRE.

MUSCULAR *flesh*. See *Muscular* FLESH.

MUSCULAR *membrane*, *membrana* MUSCULOSA, is a MEMBRANE, by some supposed to invest the whole body, immediately under the adipose membrane; called also PANNICULUS *carnosus*, and *membrana musculosa communis*.

MUSCULAR *motion*, is used for voluntary or spontaneous motion; thus called, because effected by means of the contraction and dilatation of the *muscles*.

The mechanism of a *muscle* we have delivered at large; but how this mechanism is employed to produce motion in animals, is matter of endless doubt. The generality of writers suppose the belly of the *muscle* to be swelled, and thus its extremes brought nearer; and consequently the part, it is fixed to, moved.

The structure of a *muscle* we have shewn to be such as renders it capable of being swelled and contracted, and by that means of having its extremities brought nearer each other, which is its proper action; but how the contraction is effected, is the point in dispute.

The generality account for it, from the influx of some fluid into the *muscular* fibres. Others solve it from the natural elasticity of those fibres. And the retainers to a fluid are subdivided as to the particular fluid employed for this purpose.

From the structure and phenomena of the *muscles* above laid down, we may gather the property of the hidden cause that moves the *muscles*; *viz.* 1st. that it may either be present or absent in a *muscle*; and therefore, 2dly, may enter into it, and go out again; i. e. 3dly, it is derived to it from some other place, and passes from it elsewhere: and, 4thly, all this, by an instantaneous direction of the will: 5thly, and in the same moment of time, wherein the *muscle* is contracted, it must pass from within outwards to every point of the surface of the *muscle*; that is, 6thly, it must be at once equally distributed throughout the whole belly of the *muscle*; and therefore, 7thly, it must fill and dilate the membranes of the fibres, change them from an oblong into a more spherical figure, lengthen their less diameter, and diminish their longer, and so draw the tendons nearer to each other: lastly, that it must have its rise from the cerebrum and cerebellum, the origin of the nerves, and be powerful enough to overcome those obstacles which here strongly resist it. On the whole, then, it must be a most fluid, subtile, active body; and must be applied with some energy within the *muscle*. Now all the fluids in the body that have any pretensions to these properties, that are any way qualified to produce the phenomena above, or that have been alledged as the cause of *muscular motion*, are the *animal spirits* (or, as our later writers call it, the *nervous power*) and the *blood*: but as each of these singly seems appears adequate to the effect, our authors have supposed them to mix in the *muscles*, and each to contribute to the action of the other. But

the animal ſpirits ſeem to have the greateſt number of advocates, though their exiſtence was never yet fully proved; beſides that the manner of their action as aſſigned by authors, ſeems to be arbitrary and precarious. Some, with the learned Dr. Willis, make the tendons a receptacle for the ſpirits, which are raiſed at the inſtigation of the will, and ſent thence into the belly of the *muſcle*; where meeting with the active particles of the blood, they ferment, and cauſe an intumeſcence, and ſo contract the *muſcle*.

Others, among whom are Deſcartes and his followers, allow no receptacle for them, but the brain, and ſend them thence through the nerves like lightning at every ſummons of the will; becauſe they cannot allow the tendons to be a proper lodgment, on account of the cloſeneſs of their contexture; nor can believe that the animal ſpirits ſhould remain there unactive. Others, among whom is M. du Verney, imagine this intumeſcence may be without fermentation, by the animal ſpirits, and a juice from the arteries running into the tendons and fleſhy fibres, and extending them; as ropes, &c. ſwell in moiſt weather. Dr. Cheyne, and others, maintain, that every *muſcular* fibre, beſides its vein, artery, and nerve, has alſo, from ſpace to ſpace, ſeveral little cavities, or pores of an oblong figure, when the *muſcle* is ſlack or flaccid; and that the blood, circulating through the *muſcle*, is continually depoſiting into thoſe pores a ſulphureous recrement abounding with alkaline ſalts; which meeting with the ſpirits that flow by the nerves into thoſe ſame oval pores, their nitro-aerial particles ferment with the ſaline ones of the ſulphureous recrement, and, by a kind of exploſion, ſo diſtend the pores, as to change the long oval figure into a round one: and thus the *muſcle* is contracted.

Borelli takes the fibres of a *muſcle* to conſiſt of a chain of rhombuſes or lozenges, whoſe areas are enlarged or contracted as the nervous juice, with the lympha and blood, is let into, or forced out of them, at the inſtance of the ſoul.

Dr. Croon ſuppoſes every fleſhy fibre to conſiſt of a chain of little bladders, or globules, communicating with each other; into which the nutritious juice, and one or two more liquors entering, do, by means of the natural heat, make an effervescence; by which the body of the *muſcle* is extended, &c.

Dr. Cheyne takes the ſmall fibrillæ of the *muſcles* to be ſo many ſlender elaſtic canals, bound about by ſmall tranſverſe parallel threads, which divide the hollow fibrillæ into ſo many elaſtic cyſtes or veſiculæ, which are orbicular, being formed of two concave ſegments of a ſphere; into every one of which veſiculæ, an artery, vein, and nerve enter: the two firſt to carry and bring back the blood, the laſt to carry thither the liquidum nervoſum, or nervous juice, which, mingling in the veſiculæ with the blood, does, by its acid pointed particles, prick and break the globules of the blood, ſo as to let out the impriſoned elaſtic air (contained in the globules) in thoſe little veſiculæ; whereby the elaſtic cells of the fibres will be blown up, and thereby their longitudinal diameters from cell to cell ſtraitened: and this muſt contract the length of the whole fibre, and ſo move that organ to which one of the tendons is fixed.

Dr. Keil, not contented with this theory, ſets up another, wherein the ſame ſtructure of the *muſcle* is ſuppoſed; and the ſame fluids, viz. the blood, and nervous juice, are allowed the agents or inſtruments of contraction: but inſtead of the pungent particles of the nervous juice piercing the globules of blood, and ſetting at liberty the impriſoned elaſtic aura, he reſolves the whole into the power of attraction.

According to this author, the diſtenſion of the veſicles of the fibres is not owing to their being filled with a greater quantity of blood and animal ſpirits than before their contraction; but to a rarefaction ariſing from the mixture of thoſe two fluids, by means whereof they come to poſſeſs a greater ſpace.

To account for this rarefaction of the blood and ſpirits in the veſicles of the muſcular fibres, he ſuppoſes a ſmall globule of air between the particles of a fluid, which particles have a ſtrong attractive force, whereby they endeavour to come together: by preſſing every way equally on the globule of air, they will hinder its eſcape from between them. But the force whereby they endeavour to come together, being vaſtly greater than that of gravity, the globule of air muſt be conſiderably condenſed; but the force of elaſticity being proportional to that of its condenſation, the force, wherewith the airy globule endeavours to expand itſelf, will likewiſe be vaſtly great: ſo that if the niſus of the particles of the fluid to come together ſhould be taken off, the air between them would expand itſelf with a conſiderable force. Now, if, upon the mixing of another fluid, the particles of the firſt fluid be more ſtrongly attracted to the particles of this other fluid than they were before to one another, their niſus to one another will then ceaſe, and give the incloſed globule of air liberty to expand itſelf; ſo that the whole fluid will take up a greater ſpace than it did before; but when the particles of the globules come to be united together, they will again incloſe the globule of air that lies between them; and by their mutual attraction, ſoon bring it to its former ſtate of condenſation. Now, that the blood contains a great number of globules of air, is evident from the great quantity that it yields in the air-pump; and that the particles of the blood have a ſtrong attractive force, cannot well be denied. Upon the meeting, then, of theſe two fluids in the veſicles of the fibres, the nervous juice, conſiſting of ſmaller particles than the blood, muſt, from what Sir Iſaac Newton has proved of the rays of light, attract the particles whereof they are compoſed more ſtrongly than thoſe do each other; and, conſequently, the niſus of thoſe particles to each other ceaſing, the condenſed globule of air will expand itſelf with a conſiderable force; whereby each veſſel of the fibre will be diſtended, and conſequently, therefore, ſhortened; i. e. the whole *muſcle* will be contracted: but when the particles of the blood are well mixed with the nervous fluid, they will both together incloſe the globule of air again, and compreſs it into as ſmall a ſpace as it was before: and the contraction of the *muſcle* muſt immediately ceaſe, till freſh blood and ſpirits, ſtill ſucceeding each other, continue the inflation of the veſicles. But, when a *muſcle* has been ſtrongly attracted for ſome time, the quantity of ſpirits ſpent being more than can be prepared in the ſpace of time by the glands which ſupply its nerves, the inflation of the veſicles muſt fall, and the *muſcle* grow feeble and weak. And thus that ingenious author conceives the veſicles to be diſtended, without any ebullition or effervescence; and their diſtenſion to ceaſe, without any precipitation or flying off of the aerial globules through the pores of the *muſcles*.

He proceeds to ſhew how artfully the mechaniſm of the fibres is contrived for the neceſſary contraction. It is a known experiment, that a bladder blown up, and diſtended as to its capacity, but contracted as to length, will raiſe a weight to ſome determined height: two bladders, therefore, thus blown up, and communicating with each other, he argues, will raiſe the weight double the height, and three bladders thrice the height, &c. ſo that, if there were a ſtring of bladders joined together, of equal bulk, and like figures, the ſpace through which the weight would riſe, would be proportionable to the number of bladders, i. e. to the length of the ſtring. Now, each fibre of a *muſcle*, conſiſting of an infinite number of ſmall veſicles, reſembles a chain or ſtring of bladders; ſo that the contraction of the *muſcle* is always proportionable to the length of its fibres. Farther, the veſicles, whereof the fibres conſiſt, being very ſmall, though one large bladder might raiſe a weight as high as ſeveral ſmall ones, yet the quantity of elaſtic fluid uſed in the inflation, would, in that caſe, be much greater than where the weight is raiſed by a ſtring of ſmall ones.

For, ſuppoſing two bladders of ſimilar figures, but the diameter of the one to be triple that of the other; then will the one require twenty-ſeven times the quantity of elaſtic fluid to expand it that the other does, and will alſo expand to twenty-ſeven times the ſpace; and yet three of the leſs bladders joined together (he goes on) will raiſe the weight to the ſame height that the bigger one does; but with nine times leſs expence of elaſtic fluid, and take up but a ninth part of the ſpace. By diminiſhing, therefore, the bigneſs of the veſicles, and increaſing their number, the force required to diſtend them, and the diſtenſion itſelf, may be diminiſhed in any given proportion, and may come at laſt to be inſenſible. Suppoſe a bladder, e. gr. of a determinate bigneſs, can raiſe a weight a foot; a hundred bladders, whoſe diameters are each a hundred part of the former, being blown up, will raiſe the weight to the ſame height; but the force required to inflate them, and the ſwelling of all put together, will be ten thouſand times leſs than of the large one.

Again, if a weight, of a determined bigneſs, can be raiſed to a certain height by a bladder, or one ſtring of bladders, to which the weight is tied; twice that weight may be raiſed by two ſuch bladders, or ſtrings; thrice by three, &c. and conſequently, the weight a *muſcle* can raiſe will be always as the number of its fibres, i. e. as its thickneſs, ſuppoſing the diſtenſion of the veſicles equal, and the abſolute ſtrength of one *muſcle* to that of another, as their bulks. Thus much for the once flouriſhing ſyſtem of the chain of bladders; which being liable to very great difficulties as to the geometricity of it, has of late given way to others.

Dr. Boerhaave, finding all the requiſites before laid down

for the action of the *muscles* in the nervous juice, or animal spirits, and in no other fluid in the body, thinks it needless to have recourse to a mixture of several liquors where one will do; and therefore makes no scruple to attribute the whole business to it alone. The manner of action he conceives thus:

Suppose the spirit, from any cause, to be moved more swiftly from the origin of some one nerve than through the rest; the influx will here be greater into the *muscular* fibre open to this nerve, than into another: this will therefore be more dilated, and the other phenomena, mentioned above, will succeed: the same cause continuing, the effect will be increased; so that in a moment of time, the whole will be swelled up, and while the same determination lasts, will remain contracted: and this obtaining in an infinite number of fibrillæ at once, the whole *muscle* will be inflated.

Hence it necessarily follows, that as the celerity is increased in one nerve, the motion will be less in another: this, therefore, being relaxed, the effort in contraction will be the stronger; for which reason all the turgid fibres of a *muscle* will compress the intermediate spaces and blood with a great force; whence the veins will be emptied, and the arteries, being compressed, will repel the grosser, that is, the red parts of the blood, but will drive the more subtile parts, by the force of the heart, and their own, into the most minute canals; and thus the cruor being expelled, the whole body of the *muscle* will be found to act by a subtile humour concurring from the nerves and arteries.

Thus are all the phenomena accounted for, without any other assumption than an accelerating force in the origin of the nerves; which is common to all hypotheses, and which cannot be traced any farther.

All other systems, therefore, Boerhaave absolutely rejects; nor makes the least account of Galen's incorporeal power inflating the *muscles*; the nitrous spirit of the nerves mixing with the oil of the blood, and so rarefying it; the acid parts of the nervous juice mixing with the alkalious ones of the blood; the ebullition of the air, and the arterious juice; and the increase or diminution of attractive force of the minute corpuscles of the humours; as repugnant to sense, experience, the laws of matter, and of mixtures, and to the phenomena of the *muscles*.

Dr. Astruc has gone a good way towards proving the nervous juice alone concerned in *muscular motion*; and that the blood has no share at all in it; by the following experiment, which he tried several times with the same success.

Cutting open the abdomen of a live dog, and removing the intestines out of the way, he bound up the aorta, where it divaricates into the iliac arteries, with a thread, so as to constringe each iliac and the hypogastric artery very closely; then, sewing up the epigastric *muscles*, he found the sensation and motion still as brisk and vivid in the dog's posteriors, as before: so that, when once set at liberty, he stood on all four, and walked with his usual ease and firmness; though, it is certain, there could not be one drop of blood conveyed to those hind parts.

Astruc, however, differs from Boerhaave in the manner wherein this nervous juice acts; nor will he allow that celerity, wherewith the *muscles* act at the command of the will, to be owing to the velocity of the juice sent through the nerve; but to an impression given to one extremity of the thread, and communicated through all the intermediate parts to the other extremity; supposing the nerves, in their natural state, to be turgid, and full of spirits: so that, if the extremity in the sensory be ever so little pressed by the accession of any new spirit, as much will be instantly expelled at the other extreme; and *vice versa*, a small impression given to the outer extremity of the nerve, will immediately move the other extreme open to the sensory; so that part of it will drop out: which accounts for sensation, as well as *muscular motion*. See SENSATION.

Lastly, Dr. Lower, and Mr. Cowper, and after them Dr. Morgan, and others of the latest writers on that subject, setting aside all adventitious fluids, account for *muscular motion* from the intrinsic elasticity of the nervous fibrillæ contracting and restoring themselves, against the stretching force of the circulating blood.

This system Morgan endeavours to evince from the following considerations: 1. All the vessels in an animal, consisting of flexible, distractile fibres, are in a state of tension, i. e. are both stretched transversely and longitudinally by their contained fluids: thus, e. gr. let a vein or artery be cut, and the opposite sides of the vessel will contract, and come nearly to a contact about the axis; while the two ends, receding both ways, leave a chasm: which shews, that the vessel, while in its natural state, was distended both ways; and, consequently, that contraction, in all their dimensions, is the natural intrinsic action of the vessels or fibres.

And the same might be deduced, *a priori*, from the growth of animals; for, by the increased quantity of the accumulated blood, the vessels must necessarily be enlarged every way. Now, against this distended power of the fluids, the solid *muscular* fibrillæ will continually exert a contractive or resilitive force, by which they are kept in their proper state of tension.

2. That this contractive power of the *muscular* fibres is a natural intrinsic property of the fibres themselves, and does not depend on any mixture, or mutual action of fluids, is evident from hence, that these fibres retain the same property, after they are taken out of the body, and dried, as we see in thongs, cat-gut, and other such like cords or strings cut out of the *muscular* coats and skins of animals, which may be stretched out to a considerable length beyond their natural state; and when the stretching force or weight is taken off, they will immediately contract again by their native spring.

3. While a *muscle* contracts, the blood is squeezed out; and, during its state of contraction, it is more hard and solid than before; that is, it contains less blood when contracted than when stretched; which shews, that the contraction cannot be by the addition of another fluid from the nerves, mixing with the blood in the *muscles*.

4. No such fluid in the nerves could ever be found, as, being mixed with the blood, would occasion such fermentation or expansion: but, supposing the *muscular* cells thus inflated, no such effect could follow, as shortening the *muscle* in length, and swelling it in thickness; but the consequence must be, that the *muscle* would be lengthened, as well as thickened; that is, it must increase its dimensions proportionably every way; which is the proper action of fluids on the solids.

If, then, it be said, that these bladders, when the *muscle* is stretched, are drawn into oblong spheroids; and when inflated by the mixture of the nervous fluid, reduced to a spherical figure, by which means their axes are shortened, and their conjugate diameters enlarged; it is answered, that those small vesicles are soft, flexible, distractile, and equally yielding every way; and, since an included expansive fluid must press its containing vessels equally yielding every way, and equally expansive, a vessel, notwithstanding such distension, must retain its natural figure, and be equally stretched in all directions.

Again, since the blood circulates freely through these *muscular* cells, it is plain, that, as soon as they begin to inflate, it must be immediately pushed forward with an increased velocity in the course of its circulation, which must prevent any such inflation in the *muscles*. Before these vesicles, therefore, can be distended in the manner supposed, the exit of the fluid must be hindered; that is, the circulation must be stopped. If *any* one doubt of this, let him try whether he can blow up a bladder, or other vessel, that is open at both ends, and where the expansive fluid has as free an egress as ingress.

Thus much premised, the natural action of a muscle will be easily explained. From its structure it follows, that, on the contraction of its transverse and spiral fibres, which are the ramifications of the nerves, the longitudinal, red, and fleshy fibres, or blood-vessels, which constitute the body of the muscle, must necessarily be squeezed and drawn together, as being compelled to follow the motion of these elastic cords; by which means the blood, being compressed, must be forced, with some impetuosity, through the muscle, and propelled forward in the course of its circulation.

Now, if the blood should hereupon stop, and return no more to the muscle, it is plain, the muscle must for ever remain in this contracted state, as its proper and natural state of quiescence, to which it tends, and where it would rest: but the blood, having received a fresh impetus by the contraction, and returning upon the muscle, in the course of its circulation, again rushes into the blood-vessels; which being enlarged in all their dimensions by the force of the returning blood, the transverse and spiral nervous fibres must be hereby stretched, and the muscle extended, till by this means, the blood-vessels being brought to their natural extent, and consequently the distending force of the blood ceasing, the contracting power of the nerves begins to act again, and restore them, with the same force by which they were extended, till the returning blood re-enters the muscle, and stretches it again.

Dr. Morton, in an inquiry into the cause of *muscular* motion, observes, that in every *muscle* there are numerous arteries, veins, and nerves; which are generally distributed together, or in the same course, by means of the connecting cellular substance, into every point of the fleshy fibres; that there is a circulation of blood, through the whole fleshy substance of a *muscle*; and that the *muscle* feels in every part. In order therefore, to the performance of voluntary *muscular* motion, besides the particular structure, there is required an absolute freedom

of

of the blood-veſſels and nerves. He farther obſerves, that *muſcular* motion is voluntary and involuntary: to the former ſubſerve almoſt all the *muſcles* of an animal body; the only complete inſtance of the latter is afforded by the heart. The contraction of the heart, he ſays, in its natural ſtate, in a living animal body, proceeds ſolely from, or is mechanically cauſed by, the warm blood, flowing into and filling its fleſhy ſubſtance in every part: and its ſubſequent relaxation is occaſioned by the removal of the blood. He farther ſhews, that a *muſcle* of voluntary motion, in its natural ſtate, in a living animal body, is contracted by the introduction of a warm mild fluid into its fleſhy ſubſtance in every part. He adds, that the nerves are the immediate inſtruments of ſenſation; and that the will hath a direct power of rendering more acute the ſenſations of the nerves univerſally: whence he infers, that the blood, which is preſent in every part of the contracting ſubſtance of a *muſcle*, and which aſſumes an increaſed heat and again parts with it at the command of the will, is the immediate mechanical cauſe, by which the *muſcle* does inſtantly contract, and is again relaxed. Phil. Tranſ. vol. xlvii. art. 47. p. 305, &c.

Dr. Brown Langrith endeavours to prove that the blood has no immediate effect in *muſcular motion*, by experiments of tying the crural and carotid arteries of dogs, who thereby did not loſe the action of any muſcles. He grants however, that when all the blood is intercepted, *muſcular motion* ceaſes in a few minutes. The chief uſe of the blood towards *muſcular motion*, is to keep the fibres warm, ſupple, diſtended, and ready for the influx of animal ſpirits into them, and by its motion to aſſiſt their's. The *muſcular* fibres are little hollow cylinders, not divided into cells; the animal ſpirits are near a-kin, or analogous to ſpirit of ſal armoniac, &c. and therefore, whenever they fly from the nerves into the *muſcular* fibres, they will increaſe the attractive quality of their component particles towards each other, ſo as to make them run nearer together, which will occaſion the coats of the fibres to be both thicker and ſhorter, and the muſcle will be contracted in all its dimenſions. The animal ſpirits are too ſubtile to be fixed, and therefore immediately make their eſcape through the fibres, and leave them in the ſame ſtate they found them in, as ſoon as the ſupply by the nerves is diſcontinued. There is a difference in the mechaniſm of the nerves ſent to the muſcles, which act by the influence of the mind, from thoſe of the muſcles which are ſaid to perform involuntary motions; the latter having no hindrance to the courſe of the animal ſpirits, unleſs ſometimes the parts through which they paſs have influence on them; whereas the nerves, which ſerve the muſcles of voluntary motion, have ſome little conſtrictions at their extremities, or elſewhere, which hinder the courſe of their fluids, except when their reſiſtance is overcome by the momentum of the ſpirits being increaſed by the will. The uſe of the ganglions is to prevent any communication of motion from one nerve to another, whereby in a ſtate of health, ſenſation is always performed diſtinctly. Eſſ. on Muſc. Motion.

Dr. Stuart having cut off the head of a frog, obſerved, that upon thruſting a probe into the *medulla ſpinalis*, the muſcles of the body were brought into convulſive contractions. And that the ſame happened to the muſcles of the head, when the probe was thruſt into the brain. From which he concludes, that the brain and nerves contribute to *muſcular motion*, in a high degree. Next he laid bare the crural artery, vein, and nerve of a dog, and placing a thread parallel to them, made two ligatures on them at four inches diſtance from each other; then cutting the veſſels through, beyond the ligatures, he took them out, and obſerved, that the nerve did not contract, though the blood-veſſels loſt three eighth parts of their length. From whence he infers, that what the nerves contribute in *muſcular motion*, cannot ariſe from, or be owing to elaſticity, but to the fluid they contain, which can be no other than a pure elementary water. Phil. Tranſ. N° 424. ſect. 5.

Dr. Prieſtley conjectures, that the ſource of *muſcular motion* is the electric matter, conſidered as a modification of PHLOGISTON: in ſupport of which he alledges, that the electric matter directed through the body of any *muſcle* forces it to contract; that the proper nouriſhment of an animal body, from which the ſource and materials of all *muſcular motion* muſt be derived, is probably ſome modification of phlogiſton; that vinous and ſpirituous liquors, which conſiſt very much of phlogiſton, inſtantly brace and ſtrengthen the whole nervous and *muſcular* ſyſtem, the phlogiſton in this caſe being, perhaps, more eaſily extricated, and by a leſs tedious animal proceſs than in the uſual method of extracting it from mild aliments; and that reſpiration and putrefaction affect common air in the ſame manner, and juſt as all other proceſſes diminiſh air and make it noxious, and which agree in nothing but the emiſſion of phlogiſton. Hence he infers, that animals have a power of converting phlogiſton, from the ſtate in which they receive it in their nutriment, into that ſtate in which it is called the electrical fluid; that the brain, beſides its other purpoſes, is the great laboratory and repoſitory for this purpoſe; that by means of the nerves, this great principle, thus extracted, is directed into the *muſcles*, and forces them to act in the ſame manner as they are forced into action, when the electric fluid is thrown into them *ab extra*. As to the manner in which the electric matter makes a *muſcle* contract, he only imagines that whatever can make the *muſcular* fibres recede from one another farther than the parts of which they conſiſt, muſt have this effect. Prieſtley on Air, vol. i. p. 176, &c.

MUSCULAR *conſumption*. See CONSUMPTION.

MUSCULAR is alſo an appellation given to ſeveral veins; two whereof come from the ſkin and the hind-muſcles of the thigh, and terminate in the ſubclavians.

There are three others in the loins alſo, called *muſculares*, and diſtinguiſhed into *upper*, *middle*, and *under*: the firſt terminates in the trunk of the vena cava, and the two others open into the external iliac vein.

MUSCULI *aliformes*. See ALIFORMES.

MUSCULI *amatorii*. See AMATORII.

MUSCULI *annuentes*. See ANNUENTES.

MUSCULI *capitis acceſſorii*. There is ſometimes found a ſmall *muſcle* fixed by one end to the extremity of the firſt tranſverſe apophyſis of the neck, near the inſertions of the two obliqui, from whence running up obliquely it is again inſerted behind the maſtoide apophyſis. This *muſcle* is commonly thought to be a third ſmall tranſverſalis, on that ſide where it is found; but it ſeems rather to be an additional *muſcle* to the obliquus ſuperior. The recti, and other obliqui, are alſo found ſometimes double. Winſlow.

MUSCULI *vermiformes*, &c. See VERMIFORMES, &c.

MUSCULOUS. See MUSCULAR.

MUSCULUS *faſcia latæ*. See MEMBRANOSUS and FASCIA *lata*.

MUSCULUS *latus*. See LATUS *muſculus*.

MUSCULUS is alſo a name by which ſome call the common ſea MUSCLE, more properly called *mytulus*.

MUSCULUS *myſticetus*, in *Ichthyology*, a name given by Gefner, and ſome other writers, to the common whale, or *balæna edentula* of authors. This is diſtinguiſhed from all the other cetaceous fiſhes by Artedi, by the name of the whale with the ſpiracle in the middle of the head, and with the back ſharp toward the tail. See WHALE.

MUSCULUS, among the Romans, a military machine, under cover of which the ſoldiers approached and undermined the walls of places beſieged, or filled the ditches.

MUSCUS, in *Botany*. See MOSS.

MUSCUS *arborescens marinus*, in *Natural Hiſtory*, a name given by count Marſigli to a very elegant ſpecies of marine ſubſtance, deſcribed by him as a ſea-plant. See CORALLINE.

It grows to the rocks at conſiderable depths under water, and is uſually of about three inches high; and is compoſed of ſeveral thick branches, furniſhed toward the tops with tranſparent leaves; the ſtalks are hollow, and it is all ſoft while in the ſea, but grows ſomewhat rigid when dried.

When examined by the microſcope, its ſurface appears to be granulated or covered with a ſort of ſmall glandules, which ſtand very near one another, and on cutting it tranſverſely the whole ſubſtance is ſeen to be hollow, and that general hollow to communicate with all theſe glandules, ſo that their office plainly is ſeverally to receive the ſea-water, and convey it it into this general cavity, where it is diſtributed throughout the whole plant for its nouriſhment and ſupport. The leaves of this plant being rubbed on blue paper, give it a yelloviſh green colour.

Count Marſigli has gone through the analyſis of this, and as by it we may be informed of the principles and properties of many other ſea-plants of the ſame genus, it may not be improper to give an abſtract of his obſervations.

Four and twenty ounces of this plant being put into a retort, there came over five ounces of phlegm of a ſweetiſh taſte, and of the colour of oil of almonds. The ſpirit was of a duſky earth colour, of a fixed nature, of an unctuous yet ſomewhat acrid taſte, and leaving a bitterneſs behind it: of this there were twelve ounces, and the remainder in the retort was ſix ounces and three drams. So that the whole produce being twenty-three ounces and three drams, there was only five drams of the whole loſt in the operation. The water does not alter the colour of blue paper, on ſteeping in it; being mixed with the decoction of mallow flowers it turns it to an aſh-colour. The decoction of galls becomes of a bluiſh colour, and a ſolution of copperas of a greeniſh aſh-colour with it:

the tincture of turnsol becomes of a bluish colour, tending to white. Spirit of nitre being added to it, causes a slight fume, and the decoction of mallow flowers being after this added, a fine red colour is produced. Spirit of vinegar turns this green; and no change at all is produced by any of the following liquors, spirit of salt, spirit of sal armoniac, lime-water, alum-water, oil of tartar: a solution of corrosive sublimate collects a quantity of white and gross particles, and precipitates them to the bottom. Marsigli, Hist. de la Mer. p. 73.

The spirit being examined with blue paper, makes no change in its colour on being steeped in it; the decoction of mallow flowers mixed with it become of a pale yellowish green; the decoction of galls changes with it to a dusky red; a solution of copperas becomes of a dirty yellow, and thick; the tincture of turnsol changes to an ash-colour. Spirit of nitre being mixed with it, causes a moderate fume without any ebullition, and the colour of the mixture is a reddish grey; on mixing the decoction of mallow flowers with this, it becomes of a yellowish red. Spirit of vinegar added, renders it more fluid and of a less dusky colour. Spirit of salt changes it to a reddish colour. Spirit of sal armoniac, and oil of tartar, make no change at all; but lime-water renders it more clear and fluid. Alum-water collects a quantity of white matter, and precipitates it; and a solution of corrosive sublimate, in like manner turns it white, and precipitates the gross parts. The *caput mortuum* yielded one dram and ten grains of fixed lixivial salt; the taste of this is but moderately acrid, and its colour a greyish white; being rubbed on blue paper it changes its colour to its own. The decoction of mallows on mixing this salt with it loses its blue colour, and becomes grey; and on frequently shaking the vessel, it finally becomes yellow. Spirit of nitre mixed with this salt does not so readily or violently effervesce with it, as with most other lixivial salts; and if a little turnsol be added to this, it becomes of the colour of red wine. Spirit of vinegar dissolves it very quickly, and becomes thick and turbid with it. Spirit of salt dissolves it very readily, but makes no fume, though a very considerable ebullition. Lime-water dissolves it slowly, and carries it to the surface; and alum-water, in like manner, on dissolving it, is covered with a thick scum at the top: corrosive sublimate added to this, precipitates the salt again, without altering its colour. Spirit of *sal armoniac*, and oil of *tartar*, make no change upon it. It is remarkable, that this plant contains no volatile salt.

MUSCUS *marinus latus*, the broad and flat sea *moss*, a sea-plant described by count Marsigli. It is found in several places at different depths, growing to the rocks and stones. Its upper surface is composed of a series of leaves of an auriculated figure, amassed together in an irregular manner; but its under-side is smooth and even, except that it is beset with a number of soft points or eminences, which are not easily distinguished by the naked eye. These, when a microscope is used, are found to be so many little white tubes of a cylindric figure; these are evidently the apertures by which the plant receives its nourishment; for in this, as in the other sea-plants in general, when the root fastens upon a rock or stone, it is not to extract nourishment from it, but only to fix itself firm in its place by it; for the whole surface of the plant takes in nourishment from the circumambient water, and every part acts as a root receiving supplies for the whole. See Moss.

MUSEAU, in *Natural History*, a term applied by Mr. de Reaumur to a sort of bladder, which the insects of the fly class are provided with, to make their way out of the shell, after their last transformation into the nymph state.

The word is French, and literally signifies a *snout* or *muzzle*.

The flies to whom nature has given this instrument, have it only during that short stage of their lives which is between their being inclosed in the membrane which covers them in the nymph state, and their first flying about at liberty. At this time, in order to their getting out of their shell, nature gives them a power of inflating and swelling out their head to a great size, and throwing out this sort of bladder from its anterior part, by which means the cap of the case or shell is thrown off, and the end of it opened by the two longitudinal lines giving way. The creature, after this, as it has no use for this singular piece of mechanism, to it has no power to exert it during the remainder of its life. Reaumur, Hist. Ins. vol. iv. p. 340. See TRANSFORMATION.

MUSERYTER, in *Zoology*, a name given by some to the fish called by authors *lucius*, a German fish, found in several parts of Germany, much approaching to our common dace.

MUSEIA, *Mouσεια*, in *Antiquity*, festivals in honour of the Muses at several places of Greece, especially among the Thespians, where solemn games were celebrated every fifth year.

The Macedonians had also a festival in honour of Jupiter and the Muses, which was celebrated with stage-plays and games, and lasted nine days, according to the number of the muses.

MUSEUM, *Mouσειον*, was originally used to signify a place in the palace of Alexandria, which took up, at least, a fourth part of the city; so called, as being destined and set apart to the *Muses*, and the sciences.

Here were lodged and entertained a great number of learned men, who were divided into companies or colleges, according to the sciences or sects whereof they were professors. And to each house or college was allotted a handsome revenue. This establishment is attributed to Ptolemy Philadelphus, who here fixed his library.

MUSEUM has hence passed into a general denomination, and is now applied to any place set apart as a repository for things that have some immediate relation to the arts, or to the Muses. See REPOSITORY and CABINET.

MUSEUM, *British*, the *museum* of the late Sir Hans Sloane, containing a great variety of the productions of nature and art, was purchased by the public at 20,000*l.* for the national use, and deposited in Montagu-house; where it may be rendered of no less general benefit to trade, than to the advancement of natural knowledge and experimental philosophy.

For the purchase of this *museum*, as well as the HARLEIAN collection of manuscripts, and the COTTONIAN *library*, an act of parliament passed in the twenty-sixth year of George II. which incorporates the trustees into a body politic, with a common seal, and empowers them to manage the concerns of this *Museum*.

The MUSEUM *at Oxford*, called the *Ashmolean Museum*, is a noble pile, erected at the expence of the university, for the promoting and carrying on several parts of curious and useful learning. It was begun in 1679, and finished in 1683, at which time a valuable collection of curiosities was presented to the university by Elias Ashmole, Esq. and the same day there repositted, and afterwards digested and put in a just order by Dr. Plot, who was constituted first keeper of the *Museum*.

Divers considerable accessions have been since made to the *Museum*; as of hieroglyphics, and other Egyptian antiquities, by Dr. Huntingdon; and of an intire mummy, by Mr. Goodyear; of a cabinet of natural curiosities, by Dr. Lister; also of divers Roman antiquities, altars, medals, lamps, &c.

Over the entrance of the *museum* in this inscription; MUSEUM ASHMOLEANUM, SCHOLA NATURALIS HISTORIÆ, OFFICINA CHYMICA.

MUSES, MUSÆ, *Mouσαι*, fabulous divinities of the ancient heathens, who were supposed to preside over the arts and sciences.

The word, according to Phornutus, is derived from the Greek, *μουσα*, which signifies the same with *ερευν, to search*: others derive it from *μαινεσθαι, similar*, or *alike*; all the sciences being bound and united together. Eusebius derives it from *μυειν, to initiate, to instruct*; Plato and Scaliger from *μωσθαι, obtervare*, because to them is attributed the invention of arts; and by them arts were produced. Lastly, Heinsius and Vossius derive it from the Hebrew מוסר, *mussar, severa, disciplina*. The *Muses* are called by various names; *Camenæ, Heliconiades, Parnassides, Aonides, Pierides, Pegasides, Aganippides, Thespiades, Libethrides*, and *Castalides*.

The ancients admitted nine *Muses*, and made them the daughters of Jupiter and Mnemosyne, or Memory. At first, indeed, their number was but three; viz. Melete, Mneme, and Aœde: Greek words signifying *meditation, memory*, and *singing*: but a certain sculptor of Sicyon, having orders to make three statues of the three *muses* for the temple of Apollo, and mistaking his instructions, made three several statues of each *Muse*: these, however, were found so beautiful, that they were all set up in the temple; and from that time they began to reckon nine *Muses*: to whom Hesiod afterwards gave names; viz. *Calliope, Clio, Erato, Thalia, Melpomene, Terpsichore, Euterpe, Polyhymnia*, and *Urania*.

Each of these were supposed to preside over their respective art; CALLIOPE over heroic poetry; CLIO over history; MELPOMENE over tragedy; THALIA over comedy; EUTERPE over wind-music; URANIA over astronomy; TERPSICHORE over the harp; ERATO the lute; POLYHYMNIA rhetoric.

They are painted as young, handsome, and modest; agreeably dressed, and crowned with flowers. Their usual abodes were about mount Helicon in Bœotia, and mount Parnassus in Phocis. Their business was, to celebrate the victories of the gods, and to inspire and assist the

the poets; and hence the cuſtom of invoking their aid at the beginning of a poem.

It muſt not, however, be imagined, that the deities, thus invoked, are conſidered, even by the ancient poets themſelves, as divine perſons, from whom they expect any real help. Under the name of *Muſe* they pray for the genius of poetry, and all the talents and circumſtances neceſſary for a happy execution of their undertaking.

Their addreſſes to the *Muſes* are mere allegories, and manners of expreſſing themſelves poetically: as when they make gods of ſleep, of fame, of revenge, and other natural and moral things.

Accordingly, the *Muſes* are of all ages, countries, and even of all religions: there are Chriſtian as well as heathen *Muſes*; Latin, Greek, Engliſh, and French, *muſes*. There are alſo *new Muſes*, who appear every day in favour of thoſe, who, diſdaining things too trite and common, chooſe to ſtrike out of the road.

When Virgil wrote his eclogues, he invoked the Sicilian *Muſes*, becauſe he imitated Theocritus: and the Sicilian poet having ſucceeded, the Roman begged for a genius as happy as that of this iſlander.

The *Muſes* of the poet Lucretius had never inſpired any perſon before him. It is plain, from the doctrine of his book, what kind of divinity it was he invoked. He addreſſes himſelf to Venus; but, at the ſame time, tells us, that none of the deities trouble themſelves with human affairs. His *Muſes*, therefore, muſt of neceſſity be mere allegories.

MUSHROOM, *fungus*, in *Botany*, the name of a genus of plants; the characters of which are theſe: it is a headed vegetable, compoſed of a pedicle crowned with a broad head, which is convex and ſmooth at the top, and hollow, foliated, lamelled or ſiſtulous on the other ſide. See *Tab.* II. and VII. *of Botany, claſs* 24. N° 4.

The ſpecies of *fungus*, enumerated by Mr. Tournefort, are ſeventy-three.

Linnæus has claſſed the *fungules* in general, the ſeveral ſpecies of the ferns, the moſſes, and algæ, under the character of *cryptogamia*; that is, ſuch plants as perform the great work of their fructification in ſecret, or at leaſt whoſe flowering and ſeeding are not obſerved ſo eaſily, as in thoſe plants which we uſually call the more perfect ones. In ſome of theſe the beſt microſcopes have not yet been able to inform us of the true manner in which this is performed, and many of the *fungules* or *muſhrooms* are of this number.

Under this order of *fungus* he enumerates four ſpecies, which are hairy, viz. *agaricus*, *boletus*, *hydnum*, and *phallus*; and ſix which are deſtitute of hair, viz. *clathrus*, *helvella*, *peziza*, *clavaria*, *lycoperdon*, and *mucor*.

Muſhrooms are plants more perfect than many people imagine; they have a regular root, a ſtalk conſiſting of ſeveral arrangements of fibres, the interſtices of which are filled up with a parenchymatous ſubſtance, leading from the root to the head or umbel; the under-ſide of this umbel is full of lamellæ or chives, every one of which is a regular pod or ſeed-veſſel. If theſe lamellæ are examined in their ſeveral ſtates, the ſeeds in them may be eaſily diſcovered, and are always found to be of a ſize and degree of maturity proportioned to the ſtate of the plant at that time; they have each of them alſo a ſiliquaceous aperture lengthwiſe, the ſeeds lying in rows ready to fall through it. The plant is eaſily and regularly propagated through theſe, and not only may be raiſed from ſeed, but, like many other plants, may be propagated by roots: the ſeveral filaments at the root producing tubercles, in the manner of the potatoe; from each of which there will ariſe new roots, and a new plant. The periods of vegetation in this plant are alſo ſufficiently regular; and the common opinion of its ſpringing up in a night, and periſhing in a day, has no foundation in reality. For, in the common way of raiſing them on hot beds, it is eaſy to find, that they often ſtand a fortnight or longer from their firſt appearance, before they are fit for the table. Phil. Tranſ. N° 472. p. 164.

Notwithſtanding that the ſeeds of ſome ſpecies of *muſhrooms* have been diſcovered, the accurate Buxbaum is of opinion, that very many plants of this genus propagate themſelves greatly by root, and are truly perennial; and this he ſupports by many ſolid arguments, draw from obſervations of the ſeveral ſpecies of *muſhroom*, or *fungus*, which are obvious, and under the eye of every obſerver, at many times of the year. Acta Petrop. vol. iii. p. 265. In ſeveral ſpecies of theſe plants there is placed round the ſtalk, at a ſmall diſtance from the head, a ſort of ring of a tough matter, reſembling the outer covering of the whole *fungus*; this uſually catches many of the ſeeds of the plant in their fall from the head when ripe, in order to the re-producing the ſpecies; and hence ſome have been of opinion, that it was placed there by the Author of Nature, in order to break the fall of the ſeeds, and preſerve them from the fury of the winds, in their falling from too great a height, in reſpect to their extreme lightneſs; but it rather appears, that the ſeeds often found on this *ring*, fall there only by accident, and are there detained by a viſcoſity with which that part of the plant abounds; and that the uſe of this ring is very different. Almoſt all the *muſhrooms* which have thick and fleſhy umbels, and fleſhy ſtems, have this ſort of ring round their ſtalk, from which, when the plant is young, and not yet in a flowering ſtate, there ariſes a membrane which connects the rim of the umbel to the ſtem, and preſerves the under part while in this ſtate; but when this time is over, the umbel, which was before an hemiſpherical figure, growing larger, and the membrane not giving way, it is torn off from the rim of the umbel, and adheres only to the ſtem. Soon after this the ſeeds ripen, and the umbel then loſing its former figure, commences almoſt a plane. This is the ſtate in which the plant is ſold in our markets under the name of *ſhops*.

When the umbel is of this figure, the ſeeds, being perfectly ripe, muſt fall upon the whole ſpace covered by the umbel, and as a part of this ſpace the ring muſt receive its ſhare of them; but there is no reaſon to believe that it receives more than are allotted to ſuch a part of the determinate ſpace on which they are to fall.

As to thoſe ſpecies of *muſhrooms* whoſe ſtems are ſlender, and their umbels thin, ſoft, and ductile, they never have this ring at all, and yet their ſeeds have often farther to fall than thoſe of the other kinds which have it, as they are uſually taller plants. The rims of the tender umbels in theſe kinds clap themſelves quite cloſe to the ſtalks, in the form of a contracted umbrella, and expand as the others do when the ſeeds are ripe; and the ſpecies of *fungules* of this kind are much more numerous than thoſe of the former, and propagate themſelves full as regularly.

Mr. Bradley mentions a hundred kinds of *muſhrooms* which he has ſeen in England, beſides thoſe very numerous ſmall ones which conſtitute the mouldineſs of liquors, fruits, &c. which laſt are ſuch quick growers, that they arrive at perfection in leſs than twelve hours.

The fungoides only differs from the *fungus* in its external form; the coralloides are alſo of the ſame ſpecies, though of a different name, as being branched like coral; and troffles come alſo under the ſame kind.

Matthiolus mentions *muſhrooms* which weighed thirty pounds each, and were as yellow as gold; Fer. Imperatus tells us, he ſaw ſome which weighed above a hundred pounds a-piece; and, to add no more, the Journal des Sçavans furniſhes us with an account of ſome, growing on the frontiers of Hungary, which made a full cart-load.

The poiſon of *muſhrooms* has been much talked of by ſeveral perſons; but there ſeems to be no certain account of any body's ever having been injured by eating the common *muſhroom*, unleſs by accident, as from the eating too many at once, and thereby over-loading the ſtomach; or by their being eaten by perſons who had a particular diſlike to them, as ſome perſons have to the moſt innocent aliments, particularly to cheeſe. If theſe *muſhrooms* had any poiſonous quality, it muſt have been often found out by the phyſicians in ſuch a place as London, where there are annually ſuch vaſt quantities of them conſumed, yet nothing of this kind is obſerved; and there ſeems, upon the whole, to be nothing hurtful in this ſpecies; though there may be many others which are truly poiſonous. Nor is it any more wonderful, that the different ſubjects of this claſs of vegetables ſhould differ in their virtues, than that thoſe of other kinds ſhould. The roots of carrots and parſnips are daily found a very wholeſome food, while thoſe of other plants of the ſame claſs, ſuch as the water-hemlock, the dropwort, and others of the umbelliferæ, are known to be poiſonous.

The ancients have taken great pains to diſtinguiſh the ſeveral kinds of *muſhrooms*, that the world might know the hurtful from the ſafe. The boletus mentioned by Juvenal, on account of the death of the emperor Claudius, is ſufficiently deſcribed by Pliny. Cluſius, among the moderns, has deſcribed a vaſt number of different ſpecies, every where diſtinguiſhing the eſculent and wholeſome from the poiſonous or pernicious kinds. The ſeveral authors who have treated of them ſince the time of Cluſius, have all mentioned the effects of ſome or other of the poiſonous kinds; and there are numerous inſtances of the miſchief done by them at one time or other. Some have been willing to aſcribe this miſchief to animalcules inhabiting the plant; but this ſeems erroneous, and particularly from the following inſtance: we have one kind of *muſhroom* growing in England, called the white acrid *fungus*. This is to extremely ſharp, that it ſtimulates the tongue, as if it had been touched with ſpirit of nitre: and Tournefort obſerves, that if rubbed

on blue paper, it turns it red in the ſame manner as that liquor, or any other of the violent acid ſpirits would: this cauſtic quality remains in the plant even after drying; and it is very evident, that we need look no farther than this for the origin of the poiſonous quality in this ſpecies.

There is another kind which is obſerved to kill the very flies as they ſettle upon it. It is not probable that ſuch plants as theſe ſhould be inhabited by any kind of animalcules, nor is it neceſſary to have recourſe to ſuch cauſes of the miſchief which enſues from the eating them, when their own juices ſeem ſo very able to have occaſioned it. Philoſ. Tranſ. N° 473 p. 54.

Mr Miller ſays, that the true eatable *muſhroom* is diſtinguiſhed from the poiſonous and unpleaſant kinds by theſe marks: when young it appears of a roundiſh form like a button, the ſtalk as well as the button being white, and the fleſhy part very white when broken, the gills within being livid. As they grow larger they expand their heads by degrees into a flat form, and the gills underneath are at firſt of a pale fleſh-colour; but as they ſtand long, become blackiſh.

In order to propagate *muſhrooms*, the meadows and paſtures ſhould be ſearched for them in Auguſt and September; and wherever they are found, the ground ſhould be opened all about the roots, where there will be found abundance of ſmall white knobs. Theſe are to be taken up with lumps of earth about them. The *muſhroom* beds ſhould be made of dung, in which there is good ſtore of litter; but this ſhould not be thrown in a heap to ferment, that dung which hath lain ſpread abroad for a month or longer is the beſt. Theſe beds ſhould be made on dry ground, and the dung laid upon the ſurface: their width at bottom ſhould be about two one-half or three feet, and length in proportion to the quantity of *muſhrooms* deſired; then lay the dung about a foot thick, covering it about four inches with ſtrong earth; upon this lay more dung about ten inches thick; then another layer of earth, ſtill drawing in the ſides of the bed, ſo as to form it like the ridge of a houſe, which may be done by three layers of dung and as many of earth; when the bed is finiſhed it ſhould be covered with litter or old thatch, to keep out the wet and prevent its drying: in this ſituation it may remain eight or ten days, by which time the bed will be in a proper degree of warmth to receive the ſpawn; the litter ſhould then be taken off, the ſides of the bed ſmoothed, and a covering of light rich earth, about an inch thick, ſhould be laid over the bed; upon this the ſpawn ſhould be put, laying the lumps two or three inches aſunder; then gently cover them about half an inch thick with the ſame light earth; and again put on the covering of litter. When theſe beds are made in the ſpring or autumn, as the weather is in thoſe ſeaſons temperate, the ſpawn will take much ſooner, and the *muſhrooms* will appear perhaps in a month after they are made; but thoſe beds which are made in ſummer when the ſeaſon is hot, or in winter, when the weather is cold, are much longer before they produce. The great ſkill in managing theſe beds is to keep them in a proper temperature of moiſture: during the ſummer ſeaſon, the beds may be uncovered to receive gentle ſhowers of rain at proper times; and in long dry ſeaſons, they ſhould be now and then gently watered: during the winter ſeaſon they muſt be kept as dry as poſſible, and ſo cloſely covered as to keep out cold. In froſty, or very cold weather, the growth of the *muſhrooms* will be promoted by laying over them ſome warm litter ſhaken out of a dung heap, interpoſing a covering of dry litter between the bed and this warm litter: and as often as the litter is found to decay, it ſhould be renewed with freſh; and as the cold increaſes, the covering ſhould be laid ſo much thicker. In this way plenty of *muſhrooms* will be produced all the year; and thoſe raiſed in beds will be much better for the table than any which are gathered in the fields. A bed thus managed, if the ſpawn takes kindly, will continue good for ſeveral months, and produce great quantities of *muſhrooms*: from theſe beds when they are deſtroyed, you ſhould take the ſpawn for a freſh ſupply, which may be laid up in a dry place until the proper ſeaſon of uſing it, which ſhould not be ſooner than five or ſix weeks, that the ſpawn may have time to dry.

The vaſt variety of known *fungoſes*, which are found regularly every ſeaſon in their proper ſoils, are not all that the naturaliſt has to enquire into the nature of; there are others whoſe productions are much more ſurpriſing. Theſe are ſuch as are only ſeen once or twice in an age, and that in places where it is very difficult to account for the manner of their production. One of theſe we had ſome years ago, which appeared upon an old piece of wood in a blackſmith's cellar in the Hay-market, and grew to twelve inches or more in height; and when cut down, appeared again at the ſame time the next year, and ſo on for ſeveral ſucceeding years, as if, contrary to the nature of the generality of theſe plants, it had a perennial root, and grew regularly from the old ſtock. This appeared to us a ſingular production, and a wholly new ſpecies; but ſo long ago as in the year 1692, Mr. Tournefort found ſuch a one growing on an old beam in the abbey at St. Germains. His deſcription of it is very accurate; and its reſemblance with our's as great as could be expected, in ſo looſe a growing plant as an irregular *fungus*. The beam on which this *muſhroom* grew was very firm and ſound in all other places, but juſt where it was rooted there was a crack, out of which moiſture ouzed; and probably the beam was in that part rotten, or worm eaten within. The ſmell of the plant was like that of others of the ſame kind, and an infuſion of a piece of it turned an infuſion of turnſol to a bright red; ſo that it manifeſtly abounded in acids.

It is not eaſy to account for the appearance of theſe plants which are ſeen ſo rarely, and that in places where no plant could be expected to grow: the only probable ſolution of the point ſeems this, that as the ſeeds of the *muſhroom* kind are all very minute, and generally in theſe ſpecies which have no lamellated heads, cover the whole ſurface of the leaves, the number of ſeeds produced by one ſuch plant muſt be numerous beyond all account, and at the ſame time light enough to float about in the air. Theſe muſt be at times thrown againſt a thouſand different bodies where there is no proper nouriſhment for them, and muſt therefore periſh; whereas, if any accidents are required to concur, to make a ſoil proper for it to grow in, wherever ſuch ſoil happens to be produced, as the air has free acceſs every where, it is not impoſſible but that, at one time or other, one of theſe ſmall ſeeds may happen to be properly depoſited. Mem. Acad. Par. 1692.

The Laplanders have a way of uſing *fungoſes*, or common toadſtools, as we call them, as the Chineſe and Japoneſe do the moxa, to cure pains. They collect the large *fungoſes* which they find on the bark of beech and other large trees, and dry them for uſe. Whenever they have pains in their limbs, they bruiſe ſome of this dried matter, and pulling it to pieces with their fingers, they lay a ſmall heap of it on the part neareſt to where the pain is ſituated, and ſet it on fire. In burning away, it bliſters up the part, and the water diſcharged by this means, generally carries off the pain. It is a coarſe and rough method, but generally a very ſucceſsful one, eſpecially when the patient has prudence enough to apply it in time, and reſolution enough to bear the burning to a neceſſary degree.

MUSHROOMS *growing out of ſtones*. Naturaliſts have of long time obſerved, that there are ſea *fungoſes* of a very different ſubſtance and ſtructure from any of the common kinds, growing on rocks, ſtones, and corals, or other marine ſubſtances, which ſeem wholly incapable of ſupplying them with any vegetable nouriſhment. Theſe have been ſuppoſed to be as it were all roots, and to take in their nouriſhment at every part of their ſurface from the circumambient water: but in the year 1730, Mr. Aleſeld obſerved a like ſort of *fungoſes* growing in places where they had no ambient fluid to afford them nouriſhment, except the air, and yet were fixed upon as unpromiſing a baſis for the ſupplying them with any, as thoſe of the ſea. Theſe were found on common flints on the ſurface of the earth. This gentleman obſerved, that a great many various ſpecies of flints which lay in part buried in the earth, and in part lying above its ſurface, were on this open part covered with a ſort of white duſt. This was in July, and in hot dry weather. Having the curioſity to examine this duſt with a microſcope, every particle of it was found to be a complete and perfect *fungus*, all of the ſame determinate figure, and much reſembling the common earth *muſhrooms*. They were white in colour, and had each a very ſhort pedicle, in many, ſcarce to be ſeen at all; their head was round and umbilicated, and very elegantly and evenly ſtriated on the upper part, the ſtriæ or furrows all running from the centre to the circumference; and the rim of each head being a little elevated. Upon the whole, they not unaptly reſembled in miniature a common tea-cup inverted, and the ſaucer inverted alſo, and placed upon it. The ſubſtance of theſe *fungoſes* was of two kinds, the one furniſhed a cortical part or covering, and the other filled up the whole internal ſpace.

The internal part was ſoft and ſpongy, and much like what the inſide of the common *muſhroom* is: this was white. The outer or cortical part was reddiſh, and rather repreſented a congeries of ſmall grains of ſand, collected into that form by ſome glutinous matter, than any ſolid or continuous body. The thin external coat of this being removed, there were ſeen within it a multitude of ſmall round globules of glaſſy ſurfaces, reflecting the light in manner of ſome of the ripe ſmooth ſummer fruits

fruits, such as the cherry, and the like. This was their appearance when freshly uncovered; but after they had been exposed some time to the air, they became flaccid, fell almost flat together, and were umbilicated, and marked with rays from a centre like those of a star.

These *fungusses*, if not injured by accidents, remain in their perfect state a long time upon the stones. Five months keeping produces no alteration in them; but at length they become flaccid, and wither, and in this state are not to be recovered by water, as many of the common land *fungusses* will, which swell, and for a time appear plump, on being wetted.

They grate harshly, like stony matter between the teeth, and resist the force of acid menstruums; they bear the great degrees of heat or cold without any injury; but if they are exposed to a flame, the outer covering of the head bursts and flies off, and these red globules come in full sight, while the rest of the *fungus* remains unaltered. The same effect is produced by plunging them into hot water; and if they be boiled in water, over a strong fire, the globules are dislodged and lost in it. If the stints, on which they are produced, are heated red hot, the *fungusses* are destroyed, and wholly disappear in the places where they were; only the fragments of the outer covering of the head remaining scattered, on different parts of the stone, like pieces of broken pots or glasses: these fragments lose their red colour, and are found grey. On the whole, it appears from these experiments, that the cortical part of this *fungus* is not of the nature of common vegetable matter, but is truly stony; so that the plant may be properly arranged among a set of *lithophyta*, or stone plants, properly so called. The author of this curious discovery observes, that he usually found many small red insects running about upon these stones, and among the clusters of *fungusses*. These afforded at least a proper retreat or asylum for them, if not food; for it is possible the internal part of the *fungusses* might be eaten by them. Act. Eruditor. ann. 1739.

Dr. Wolckamerus, in the Ephemerides of the curious, has described a stone, taken out of a mountain in Italy, which produced real *mushrooms* in the form of a bonnet, and called by the natives *fungus lucurius*. This stone is of the bigness of an ox's head, rough and uneven on its surface, and on which also are perceived some clefts and crevices. It is black in some parts, and in others of a lighter and greyish colour. Internally it is porous, and nearly of the nature of the pumice-stone, but much heavier, and it contains a small piece of flint, which is so incorporated with it as to appear to have been formed at the same time the stone itself received its form. This gives room to judge that those stones have been produced by a fat and viscid juice, which has the property of indurating whatever matter it filtrates into. The stone here spoken of, when it has been lightly covered with earth, and sprinkled with warm water, produces *mushrooms* of an exquisite flavour, which are usually round, sometimes oval, and whose borders, by their inflexions and different curvities, represent, in some measure, human ears. The principal colour of these *mushrooms* is sometimes yellowish, and sometimes of a bright purple; but they are always disseminated with different spots, of a deep orange colour, or red brown; and when these spots are recent, and still in full bloom, they produce a very agreeable effect to the sight. But what appears admirable, is, that the part of the stalk which remains adhering to the stone, when the *mushroom* has been separated from it, grows gradually hard, and petrifies in time, so that it seems that this fungites restores to the stone the nutritive juice it received from it, and that it thus contributes to its increase.

As to the form of these *mushrooms*, their root is stony, uneven, divided according to its longitudinal direction, and composed of fibres as fine as hairs, interwoven one with another. Their form on first shooting out resembles a small bladder scarce thin larger than the bud of a vine; and, if in this state they are squeezed between the fingers, an aqueous subacid liquor issues out. When they are at their full growth, their pedicle is of a finger's length, larger at top than at bottom, and becomes insensibly slenderer in proportion as it is nearer the earth. These *mushrooms* are also formed in an umbella, and variegated with an infinity of little specks situate very near one another. They are smooth and even on the upper part, but underneath leafy like the common *mushrooms*. Their taste is likewise very agreeable, and the sick are not debarred eating of them, when they have been dressed in a proper manner.

Upon a chemical analysis of this stone, it yielded by distillation, first an insipid water, and afterwards a spirituous liquor. When the retort was heated to a certain point, there arose an oil resembling in smell and taste that of guaiacum; and a very acrid salt was extracted from the ashes. Dr. Hill has also published an account of a similar stone, which, on being watered, produced excellent *mushrooms*.

MUSHROOM, *bastard*. See FUNGOIDES.

MUSHROOM, *pepper*. See PEPPER.

MUSHROOM *galls*, in *Natural History*, a name given by authors to a small species of galls very common on the leaves of the oak in September and October, and resembling the common esculent *mushroom*. They are placed on the upper surface of the leaf, and are often in great numbers on it. The leaves, which have considerable numbers upon them, make a very beautiful figure, and appear as if ornamented by art with a number of elegant figures. These galls are usually about a sixteenth, though sometimes a tenth of an inch in the diameter; they are composed of an orbicular head, which adheres to the leaf by a very short pedicle, so that its edges, which droop a little in the manner of those of the common *mushroom*, usually touch the surface of the leaf all round. These little galls are of various colours, according to their different degrees of maturity; they are of a greenish white at first, after that they become of a yellowish tinge, from which they pass through all the shades of orange and flame colour, to a very beautiful red, which is always their colour when perfectly mature. When they are observed by the microscope, their surface appears hairy, and the several hairs all stand near one another at their bases, and diverge at their points, as is the natural consequence of their standing on a convex body. Reaumur, Hist. Insects, vol. vi. p. 194.

The use, as well as the figure of this gall is very singular. Malpighi and Mr. Reaumur have both described it, and the former of these authors describes a cavity in the centre of the head; but this seems to have been done at random, and rather supposed from analogy, than seen in fact; for the latter author, who is perhaps one of the most accurate observers that ever wrote, could never find any cavity in any one of the great numbers he dissected; but he observed what was an use of the same kind with that of the other galls, in this, though performed in different manner; they are plainly all destined for the lodgment and security of small animals; not to be distinctly seen without the help of glasses; but they are of the nature of those worms which turn into two-winged flies.

The flies into which these worms are finally transformed, have not yet been discovered; but this is no wonder, since the animals themselves are so minute as to require glasses to view them. It is probable that they undergo their change into the chrysalis state in some other place, for they are never found in it under the galls; but this is common also to many other species.

MUSHROOM *worms*. The various species of *mushrooms* are subject to be eaten and destroyed by a great variety of insects. There is however one species which is more frequent than all the rest, and which has therefore obtained, among authors, the name of the *mushroom worm*. This is a white worm, with a hard scaly black head; it has some fleshy tubercles, which it throws out at pleasure from the under part of its several rings, and which serve it as legs. This is found indifferently in almost all the species of *mushrooms*; but in none so frequently as in the great wood-*fungus*, which is porous and greenish underneath. It is found to change to a tipula or long-legs, of no great beauty, being of a dusky brown colour, and middling size.

The other species of *fungusses* have also their worms; but there is one of a very singular nature which is found frequently on the agaric which grows on the stumps of oak trees, especially near the roots. This is a long and slender worm, somewhat flatted, and resembling a small leech, but that it has a hard and scaly head of a blackish colour. The body is composed of many rings, in the manner of the earth-worm, and looks very bright and glossy, being always covered with a viscous liquor. This creature is easily found, for it never eats into the substance of the *fungus*, but only crawls about its surface; the traces, wherever it has been, are marked with a coat of a shining varnish, and resemble the places over which snails have crept.

This worm makes a very beautiful object for a microscope. When young it is as transparent as glass, and the motion of its internal parts is very easily distinguished. When this creature is to pass into the chrysalis state, it does not remove from the *fungus*, but spins itself a web, and remains upon it. This web is composed of the same matter with the covering or habitation under which it usually resides, but it is thicker, more opake, and of a coarser structure.

The creature remains about a fortnight under this covering, and then comes forth in the form of a fly, which is evidently a species of tipula. It has very long legs, and a long and slender body; the body is brown, and the breast yellowish; the wings are long and slender, and the antennæ

antennæ are of a very singular and remarkable figure; they are broad and flat, and yet terminate in a point. Theſe are compoſed of ſeveral articulations, and make a very beautiful figure when examined by the microſcope.

Beſide theſe, this fly has, in the manner of the other tipulæ, a pair of beards placed on the anterior part of the head, which at pleaſure bends down over the face, and completely covers with them the longitudinal fiſſure, which is the mouth, ſituated in this as in the other tipulæ. Reaumur, Hiſt. Inſ. vol. ix. p. 23. ſeq.

MUSIC, *Μουσικη*, the ſcience of ſound, conſidered as capable of producing melody, or harmony; or, the art of diſpoſing and conducting ſounds, conſidered as grave and acute; and of proportioning them among themſelves, and ſeparating them by juſt intervals, pleaſing to the ſenſe.

The word is ſuppoſed originally formed from *muſa*; *muſe*; the Muſes being ſuppoſed to be the inventors thereof. Kircher, however, will have it take its name from an Egyptian word, as ſuppoſing its reſtoration after the flood to have begun there, by reaſon of the reeds, &c. on the banks of the Nile. Heſychius tells us, the Athenians gave the name *muſici*, *μουσικοι*, to every art.

Mr. Malcolm defines *muſic* a ſcience, that teaches how ſounds, under certain meaſures of tune and time, may be produced, and ſo ordered or diſpoſed, as that, either in conſonance, or ſucceſſion, or both, they may raiſe agreeable ſenſations.

Muſic, among the ancients, was taken in a much more extenſive ſenſe than among the moderns. What we call the ſcience of *muſic*, was by the ancients rather called HARMONICA.

MUSIC, *modern*, *muſica moderna*, may be divided into two parts: firſt, *antiqua-moderna*, which is generally a ſerious ſort of *muſic*, conſiſting of many parts; and which has been in uſe from Guido's time, to the beginning of the laſt century. Secondly, the *modern* which has been uſed in this and the laſt century: it is very different from the *antiqua-moderna*, being briſker, lighter, gayer, and more ſprightly.

Muſic naturally divides itſelf into *ſpeculative* and *practical*.

MUSIC, *ſpeculative*, is the knowledge of the *materia muſica*, or how to produce ſounds in ſuch relations of tune and time, as ſhall be agreeable in conſonance, or ſucceſſion, or both.

By which we do not mean the actual production of theſe ſounds by an inſtrument or voice, which is merely the mechanical or effective part; but the knowledge of the various relations of tune and time, which are the principles, out of which the pleaſure ſought is derived.

MUSIC, *practical*, is that, which ſhews how theſe principles are to be applied; or how ſounds, in the relations they bear to *muſic* (as thoſe are determined in the ſpeculative part), may be ordered, and variouſly put together in ſucceſſion and conſonance, ſo as to anſwer the end.

And this we call the art of *compoſition*, which is properly the practical part of *muſic*.

Some add a third branch, viz. *inſtrumental muſic*, or the knowledge of inſtruments; but, as this depends altogether on the firſt, and is only an application or expreſſion of it, it cannot come regularly under the definition, and conſequently is no part of the diviſion of the ſcience.

The *firſt* branch, which is the contemplative part, divides itſelf into theſe two; viz. the knowledge of the *relations and meaſures of tune*, and the *doctrine of time*.

The former is properly what the ancients call *harmonica*, or the doctrine of harmony in ſounds, as containing an explication of the grounds, with the various meaſures and degrees of the agreement of ſounds in reſpect of their tune.

The latter is what they called *rhythmica*, becauſe it treats of the number of ſounds or notes, with reſpect to time; containing an explication of the meaſures of long and ſhort, or ſwift and ſlow, in the ſucceſſion of ſounds.

The *ſecond* branch, or the practical part of *muſic*, as naturally divides into two parts, anſwering to the parts of the firſt.

That correſponding to the harmonica, the ancients called *melopœia*, becauſe it contains the rules of making ſongs, with reſpect to tune, and harmony of ſounds; though we have no reaſon to think the ancients had any thing like compoſition in parts.

That which anſwers to the rhythmica, they call *rhythmopœia*; containing rules for the application of their numbers and time.

We find a ſtrange diverſity in the ancient writers, as to the nature, office, extent, diviſion, &c. of *muſic*.

Hermes Triſmegiſtus defines *muſic* to be the knowledge of the order of all things; which is alſo the doctrine of the Pythagorean ſchool, and of the Platoniſts, who teach, that every thing in the univerſe is *muſic*. Agreeable to which wide ſenſe, ſome diviſe *muſic* into *divine* and *mundane*.

MUSIC, *divine*, is that reſpecting the order and harmony, which obtains among the celeſtial minds.

MUSIC, *mundane*, is that which reſpects the relations and order of every thing elſe in the univerſe.

Though Plato, by *divine muſic*, underſtands that which exiſts in the divine mind, viz. thoſe archetypal ideas of order and ſymmetry, according to which God formed all things. And, as this order exiſts in the mundane creatures, he calls it *mundane muſic*.

This laſt ſpecies the ancients again ſubdivided into four, viz.

MUSIC, *elementary*, or the harmony of the elements of things.

MUSIC, *celeſtial*, or the *muſic of the ſpheres*; comprehending the order and proportions in the magnitudes, diſtances, and motions, of the heavenly bodies, and the harmony of the ſounds reſulting from thoſe motions.

MUSIC, *human*, which conſiſts chiefly in the harmony of the faculties of the human ſoul, and its various paſſions; and is alſo conſidered in the proportion, temperament, and mutual dependence, of the parts of the body. Laſtly,

MUSIC, properly ſo called, which has for its object motion, conſidered as under certain regular meaſures and proportions, by which it affects the ſenſes in an agreeable manner.

Now, as motion belongs to bodies, and as ſound is the effect of motion, and cannot be without it, but all motion does not produce ſound; hence this laſt branch of *muſic* became farther ſubdivided.

Where the motion is without ſound, or as it is only the object of ſight, it was either called *muſica organica*, or *ſaltatoria*, which contains the rules for the regular motions of dancing: or *muſica hypocritica*, which reſpects the motions and geſtures of the pantomimes.

When the motion is perceived only by the ear, i. e. when ſound is the object of *muſic*, there were three ſpecies; viz. *Harmonica*, which conſiders the differences and proportions with reſpect to grave and acute. *Rhythmica*, which reſpects the proportion of the ſounds as to time, or the ſwiftneſs and ſlowneſs of their ſucceſſions. And *metrica*, which belongs properly to the poets, and reſpects the art of making verſes.

Ariſtides Quinctilianus, Bacchius, and ſome other ancient writers, define *muſic* the knowledge of ſinging, and of the things belonging thereto; which they explain by the motions of the voice and body: as if the ſinging conſiſted only in the different tones of the voice.

The ſame Ariſtides, conſidering *muſic* in the largeſt ſenſe of the word, divides it into *contemplative* and *active*. The firſt, he ſays, is either *natural* or *artificial*. The *natural* is either *arithmetical*, which conſiders the proportion of numbers; or *phyſical*, which examines the order of the things of nature.

The *artificial* he divides as above, into *harmonica*, *rhythmica*, and *metrica*.

The *active*, which is the application of the *artificial*, as either *enunciative* (as in oratory); *organical* (or inſtrumental performance); *odical* (for voice and ſinging); *hypocritical* (in the motions of the pantomimes.) To which ſome add *hydraulical*, though, in reality, no more than a ſpecies of the organical; in which water is uſed, for the producing or modifying of ſound.

Porphyry makes another diviſion of *muſic*, taking it in the limited ſenſe, as having motion, both dumb and ſonorous, for its object; and, without diſtinguiſhing the ſpeculative and practical, he makes its parts theſe ſix; viz. *rhythmica*, for the motions of dancing; *metrica*, for the cadence and recitation; *organica*, for the practice of inſtruments; *poetica*, for the numbers and feet of verſes; *hypocritica*, for the geſtures of the pantomimes; and *harmonica*, for ſinging.

Alypius alſo and Voſſius make the *harmonica*, *rhythmica*, and *metrica*, to be ſo many parts of *muſic*. Ariſtoxenus adds the *organica*. Voſſius alſo, to the three ſpecies of practical *muſic*, *harmonica*, *organica*, and *hydraulica*, adds a fourth, *orcheſtica*, or dancing.

The *muſical faculties*, as they call them are *melopœia*, which give rules for the tones of the voice or inſtrument; *rhythmopœia*, for motions; and *poeſis*, for making verſes. See POETRY.

Muſic appears to have been one of the moſt ancient of arts; and, of all others, *vocal muſic* muſt undoubtedly have been the firſt kind. For man had not only the various notes of his own voice to make his obſervations on, before any other art or inſtrument was found out, but had the various natural ſtrains of birds to give him occaſion to improve his own voice, and the modulations of ſounds it was capable of.

Of

Of many ancient authors, who agree in this conjecture, we shall only mention Lucretius, who says,

At liquidas avium voces imitarier ore
Ante fuit multo, quam levia carmina cantu
Concelebrare homines possent, aurisque juvare.

The firſt invention of ſtringed inſtruments, the ſame poet aſcribes to the obſervation of the winds whiſtling in the hollow reeds.

As for other kinds of inſtruments, there were ſo many occaſions for cords or ſtrings, that man could not be long in obſerving their various ſounds; which might give riſe to ſtringed inſtruments.

And for the pulſatile inſtruments, as drums and cymbals, they might ariſe from the obſervation of the naturally hollow noiſe of concave bodies.

Plutarch, in one place, aſcribes the firſt invention of *muſic* to the god Apollo; and, in another, to Amphion, the ſon of Jupiter and Antiope. This laſt, however, is pretty generally allowed to have been the firſt who brought *muſic* into Greece, and to have been the inventor of the lyre. The time he lived in is not agreed upon.

To him ſucceeded Chiron, the centaur; Demodocus; Hermes Trifmegiſtus; Olympus; Orpheus, whom ſome make the firſt introducer of *muſic* into Greece, and the inventor of the lyra; to whom add Phemius, and Terpander, who was contemporary with Lycurgus, and ſet his laws to *muſic*. To him ſome attribute the firſt inſtitution of *muſical* modes, and the invention of the lyre. Laſtly, Thales, and Thamyris, who is ſaid to have been the firſt inventor of inſtrumental *muſic* without ſinging.

Theſe were the eminent muſicians before Homer's time: others, of a later date, were, Laſus Hermionenſis, Melanippides, Philoxenus, Timotheus, Phrynis, Epigonius, Lyſander, Simmicus, and Diodorus; who were all conſiderable improvers of *muſic*. Laſus is ſaid to have been the firſt author who wrote on *muſic*, in the time of Darius Hyſtaſpis; Epigonius invented an inſtrument of forty ſtrings, called the *epigonium*; Simmicus alſo invented an inſtrument, called *ſimmicium*, of thirty-five ſtrings; Diodorus improved the *tibia*, by adding new holes; and Timotheus the *lyre*, by adding a new ſtring; for which he was fined by the Lacedemonians.

As the accounts we have of the inventors of *muſical* inſtruments among the ancients are very obſcure; ſo are alſo the accounts what thoſe inſtruments were; we ſcarce know any thing of moſt of them, beſides the bare name.

The general diviſion of inſtruments is, into *ſtringed inſtruments*, *wind inſtruments*, and thoſe of the *pulſatile* kind. Of *ſtringed inſtruments*, we hear of the *lyra*, or *cithara*, the *pſalterium*, *trigonum*, *ſambuca*, *pectis*, *magas*, *barbiton*, *teſtudo*, *epigonium*, *ſimmicium*, and *pandoura*; which were all ſtruck with the hand, or a *plectrum*; and which ſee in their places.

Of *wind inſtruments*, we hear of the *tibia*, *fiſtula*, *hydraulic organs*, *tuba*, *cornua*, and *lituus*.

The *pulſatile inſtruments* were, the *tympanum*, *cymbalum*, *crepitaculum*, *tintinnabulum*, *crotalum*, and *ſiſtrum*.

Muſic has ever been in the higheſt eſteem in all ages, and among all people; nor could authors expreſs their opinion of it ſtrongly enough, but by inculcating, that it was uſed in heaven, and was one of the principal entertainments of the gods, and the ſouls of the bleſſed.

The effects aſcribed to it, by the ancients, are almoſt miraculous: by means hereof, diſeaſes are ſaid to have been cured, unchaſtity corrected, ſeditions quelled, paſſions raiſed and calmed, and even madneſs occaſioned. Athenæus aſſures us, that anciently all laws, divine and civil, exhortations to virtue, the knowledge of divine and human things, lives and actions of illuſtrious men, were written in verſe, and publicly ſung by a chorus to the ſound of inſtruments; which was found the moſt effectual means to impreſs morality, and a right ſenſe of duty, on the mind.

Muſic made a very conſiderable part of the diſcipline of the ancient Pythagoreans, and was uſed by them to draw over the mind to laudable actions, and ſettle in it a paſſionate love of virtue. It was their doctrine, that the ſoul itſelf conſiſts of harmony; and therefore, by *muſic*, they pretended to revive the primitive harmony of its faculties. By this primitive harmony, they meant that, which, according to their dogma, was in the ſoul in its pre-exiſtent ſtate in heaven.

Dr. Wallis has endeavoured to account for the ſurpriſing effects aſcribed to the ancient *muſic*; and charges them principally on the novelty of the art, and the hyperboles of the ancient writers: nor does he doubt, but the modern *muſic*, *cæteris paribus*, would produce effects at leaſt as conſiderable as the ancient. The truth is, we can match moſt of the ancient ſtories of this kind in the modern hiſtories. If Timotheus could excite Alexander's fury with the Phrygian mode, and ſooth him into indolence with the Lydian; a more modern muſician is ſaid to have driven Eric, king of Denmark, into ſuch a rage, as to kill his beſt ſervants. Dr. Niewentyt tells us of an Italian, who, by varying his *muſic* from briſk to ſolemn, and ſo *vice verſâ*, could move the ſoul ſo, as to cauſe diſtraction and madneſs; and Dr. South has founded his poem, called Muſes Incantans, on an inſtance he knew of the ſame thing.

Muſic, however, is not only found to exert its force on the affections, but on the parts of the body alſo: witneſs the Gaſcon knight, mentioned by Mr. Boyle, who could not contain his water at the playing of a bag-pipe; the woman, mentioned by the ſame author, who would burſt out in tears at the hearing of a certain tune, with which other people were but a little affected. To ſay nothing of the trite ſtory of the TARANTULA, we have an inſtance, in the Hiſtory of the Academy of Sciences, of a muſician's being cured of a violent fever, by a little concert occaſionally played in his room.

Nor are our minds and bodies alone affected with ſounds, but even inanimate bodies are ſo. Kircher tells us of a large ſtone, that would tremble at the ſound of one particular organ-pipe; and Morhoff mentions one Peter, a Dutchman, who could break rummer-glaſſes with the tone of his voice. Merſenne alſo tells us of a particular part of a pavement, that would ſhake and tremble, as if the earth would open, when the organs played. Mr. Boyle adds, that ſcales will tremble at the ſound of organs; that he has felt his hat do ſo under his hand, at certain notes both of organs and diſcourſe; and that he was well informed, every well-built vault would thus anſwer to ſome determinate note.

There is a great diſpute among the learned, whether the ancients, or moderns, beſt underſtood and practiſed *muſic*? Some maintain, that the ancient art of *muſic*, by which ſuch wonderful effects were performed, is quite loſt; and others, that the true ſcience of harmony is now arrived to much greater perfection than was known or practiſed among the ancients.

This point ſeems no other way to be determinable but by comparing the principles and practice of the one with thoſe of the other. As to the theory or principles of harmonics, it is certain we underſtand it better than the ancients; becauſe we know all that they knew, and have improved conſiderably on their foundations. The great diſpute then lies on the practice; with regard to which it may be obſerved, that, among the ancients, *muſic*, in the moſt limited ſenſe of the word, included *harmony*, *rhythmus*, and *verſe*; and conſiſted of verſes ſung by one or more voices alternately, or in choirs, ſometimes with the ſound of inſtruments, and ſometimes by voices only. Their muſical faculties, we have already obſerved, were *melopœia*, *rhythmopœia*, and *poeſis*; the firſt whereof may be conſidered under two heads, viz. *melody*, and *ſymphony*. As to the latter, it ſeems to contain nothing but what relates to the conduct of a ſingle voice, or making what we call *melody*. The ancients do not appear to have ever thought of the concert, or harmony of parts; which is a modern invention, for which we are beholden to Guido Aretine, a Benedictine friar.

We would not, however, be here underſtood to mean, that the ancients never joined more voices or inſtruments than one together in the ſame ſymphony; but that they never joined ſeveral voices ſo as that each had a diſtinct and proper melody, which made among them a ſucceſſion of various concords, and were not in every note uniſons, or at the ſame diſtance from each other as octaves. This laſt indeed agrees to the general definition of the word *ſymphonia*; yet it is plain, that in ſuch caſes there is but one ſong, and all the voices perform the ſame individual melody. But when the parts differ, not by the tenſion of the whole, but by the different relations of the ſucceſſive notes, this is the modern art, which requires ſo peculiar a genius, and on which account the modern *muſic* ſeems to have much the advantage of the ancient. For farther ſatisfaction on the ſubject, ſee Kircher, Perrault, Dr. Wallis, Mr. Malcolm, the Jeſuit Cereeau, and others; who unanimouſly agree, that after all the pains they have taken to know the true ſtate of the ancient *muſic*, they could not find the leaſt reaſon to think there was any ſuch thing in their days as *muſic* in parts.

The ancient muſical notes are very myſterious and perplexed: Boethius and Gregory the Great firſt put them into a more eaſy and obvious method. In the year 1204, Guido Aretine, a Benedictine of Arezzo in Tuſcany, firſt introduced the uſe of a ſtaff with five lines, on which, with the ſpaces, he marked his notes by ſetting a point up and down upon them, to denote the riſe and fall of the voice; though Kircher mentions this artifice to have been in uſe before Guido's time.

Another contrivance of Guido's was to apply the six musical syllables, *ut, re, mi, fa, sol, la*, which he took out of the Latin hymn:

UT *queant laxis* RE*sonare fibris*
MI*ra gestorum* FA*muli tuorum*,
SOL*ve polluti* LA*bii reatum*,
O Pater Alme.

We find another application of them in the following lines:

UT RE*sidit* MI*sarum* FA*tum*, SOL*atosque* LA*bores*
Aevi sit dulcis musica, noster amor.

Besides his notes of *music*, by which, according to Kircher, he diſtinguiſhed the tones, or modes, and the ſeats of the ſemitones, he alſo invented the ſcale, and ſeveral muſical inſtruments, called *polyplectra*, as ſpinets and harpſichords.

The next conſiderable improvement was in 1330, when Joannes Muris, or de Muris, doctor at Paris (or as Bayle and Gefner make him, an Engliſhman), invented the different figures of notes, which expreſs the times or length of every note, at leaſt their true relative proportions to one another, now called *longs, breves, ſemi-breves, crotchets, quavers*, &c.

The moſt ancient writer of *muſic*, we have already obſerved, was Laſus Hermioenſis; but his works, as well as thoſe of many others both Greek and Roman, are loſt. Ariſtoxenus, diſciple of Ariſtotle, is the eldeſt author extant on the ſubject: after him came Euclid, author of the Elements; Ariſtides Quintilianus wrote after Cicero's time. Alypius ſtands next; after him Gaudentius the philoſopher, and Nicomachus the Pythagorean, and Bacchius. Of which ſeven Greek authors we have a fair copy, with a tranſlation and notes, by Meibomius.

Ptolemy, the celebrated mathematician, wrote in Greek of the principles of harmonics, about the time of the emperor Antoninus Pius. This author keeps a medium between the Pythagoreans and Ariſtoxenians. He was ſucceeded at a conſiderable diſtance by Manuel Bryennius.

Of the Latins we have Boethius, who wrote in the time of Theodoric the Goth; and one Caſſiodorus, about the ſame time; Martianus, and St. Auguſtine, not far remote.

Of the moderns, are Zarlin, Salinas, Vincenzo Galileo, Doni, Kircher, Merſenne, Paran, De Caux, Perrault, Wallis, Deſcartes, Holder, Malcolm, &c.

MUSIC, *chromatic*, *muſica chromatica*, among the Italians, is uſed to expreſs that kind of *muſic* in which there are many chromatic ſigns, as flats or ſharps, and intervals, &c. See CHROMATIC.

MUSIC, *diatonic*. See DIATONIC.

MUSIC, *didactic*, *muſica didactica*, that part of ſpeculative *muſic* which only conſiders the quantity, proportions, and different qualities of ſounds.

MUSIC, *dramatic*, *muſica dramatica*, *ſcenica*, *theatrale*, among the Italians, is uſed to denote ſuch compoſitions of *muſic* as are particularly made and fitted for theatres. See RECITATIVO.

MUSIC, *enharmonic*. See ENHARMONIC.

MUSICA *enunciativa*, or *enarrativa*, is uſed in much the ſame ſenſe as *muſica ſignatoria*.

MUSIC, *figurate*, *muſica figuralis*, *figurata*, or *colorata*. *Figurate muſic*, that wherein the notes are of different values, and the motions various, now ſlow, then quick, &c.

MUSIC, *harmonic*, *muſica harmonica*, among the Italians, is uſed for pieces conſiſting of many parts, which, though very different, yet, when played together, make an agreeable whole. This we call *muſic* in parts.

MUSIC, *hiſtorical*. See HISTORICAL.

MUSIC, *hypercbematic*, or *cborale*, is uſed by ſome authors for a ſort of *muſic* fit for ballads and dancing.

MUSIC, *inſtrumental*, is uſed to denote muſical compoſitions, made to be executed by inſtruments.

MUSIC, *melismatic*, or *melodia*, is uſed to denote a ſong, or ſingle part, merely for a voice or for an inſtrument. Broſſard. See MELODY.

MUSIC, *melopœtic*, is the ſcience or art of ranging and diſpoſing ſounds in ſucceſſion in an agreeable manner; or the art of making melody. See MELODY and MELOPŒIA.

MUSIC, *menſural*, *muſica miſurata*, among the Italian authors, a kind of *muſic*, the notes of which are unequal. It is contrary to *muſica plana*, or *chorale*.

MUSIC, *metabolic*, *muſica metabolica*, among the Italians, is properly *muſic* tranſpoſed, as when the piece goes out of its natural mode into a tranſpoſed one, the better to expreſs the words, or to diſtinguiſh ſome change in the action, paſſion, motion, &c.

MUSIC, *metric*, *muſica metrica*, is uſed, by Italian authors, to denote the harmonious cadence of the voice, heard when any one declaims, or repeats verſes; or it is an air compoſed to verſes.

MUSIC, *modern*. See ante.

MUSIC, *modulatory*, *muſica modulatoria*, among the Italians, that part of *muſic* which teaches to compoſe or modulate, i. e. that fixes rules for the uſe of modes, and teaches either to ſing or play well. See MODE, and MODULATION.

MUSIC, *odic*, *muſica odica*, among the Italians, is the ſame with *hypercbematic*, or *cborale*.

MUSIC, *organic*, *muſica organica*, among the Italians, is uſed to denote muſical compoſitions deſigned to be performed by inſtruments only.

MUSIC, *pathetic*, *muſica pathetica*, is a moving and affecting kind of *muſic*, that cauſes emotions in the mind, either of love, grief, or pity.

MUSIC, *poetic*, *muſica poetica*, is ſometimes uſed for the art of inventing ſongs, of modulating concords and diſcords together agreeably, and making what we call compoſitions, &c.

MUSIC, *recitative*, *muſica recitativa*, *ſcenica*, or *dramatica*, a ſort of *muſic* uſed in operas, &c. irregular as to time, being a declamation in ſinging, to expreſs the paſſions. From its being thus irregular in its time, the Italians often place the phraſe *a tempo giuſto*, when the recitative ends, and an air, be it minuet, jigg, or any other, follows, to ſhew that the time is then ſtrictly to be obſerved. See RECITATIVO.

MUSIC, *rhythmic*, *muſica rhythmica*, is uſed for the harmony or cadence of the words in proſe; or a ſong compoſed to words in proſe.

MUSIC, *ſcenic*, the ſame with *recitative*.

MUSIC, *ſignatory*, *muſica ſignatoria*, is uſed for that part of *muſic* which teaches the knowledge of the characters, notes, figures, paſſes, and all other ſigns and marks whatever, uſed in *muſic*.

MUSIC, *vocal*, *muſica vocalis*, or that compoſed for the voice, in oppoſition to organical or inſtrumental, which is intended to be played on inſtruments only.

MUSIC-*ſhell*, in *Natural Hiſtory*, the name of a ſpecies of ſhell-fiſh of the MUREX-kind, remarkable for its variegations, which conſiſt of ſeveral ſeries of ſpots placed in rows of lines, like the notes of *muſic*.

MUSIC, *academy of*. See ACADEMY.

MUSIC, *characters in*. See CHARACTERS.

MUSICAL *accent*. See ACCENT.

MUSICAL *faculties*. See MUSIC.

MUSICAL *glaſſes*. See ARMONICA.

MUSICAL *modes*. See MODE.

MUSICAL *notes*. See NOTE.

MUSICAL *numbers*, are 2, 3, and 5, together with their compoſites. They are ſo called, becauſe all the intervals of muſic may be expreſſed by ſuch numbers. See INTERVAL.

This is now generally admitted by *muſical* theoriſts. Mr. Euler ſeems to ſuppoſe, that 7 or other primes might be introduced; but he ſpeaks of this as a matter doubtful and difficult. It is to be obſerved, that 2 correſponds to the octave, 3 to the fifth, or rather to the twelfth, and 5 to the third major, or rather the ſeventeenth. From theſe three may all other intervals be found.

A table of *muſical* numbers within any propoſed limit may be thus expeditiouſly formed.

Place the terms of the progreſſion 1, 5, 25, 125, &c. in a column under each other; and multiply every term of this progreſſion by 3, continually, till you foreſee that the products will exceed the propoſed limit. Then if all the numbers thus found be doubled continually, till it be foreſeen that the doubled numbers would exceed the propoſed limit; all theſe products together, with the powers of 2, will give the *muſical* numbers required.

Thus if it were required to find all the *muſical* numbers within the compaſs of eleven octaves; that is, between 1 and 2048; form the column 1, 5, 25, &c. and multiply every term by 3, continually, as in the annexed example:

1. 3. 9. 27. 81. 243. 729, &c.
5. 15. 45. 135. 405. 1215, &c.
25. 75. 225. 675. 2025, &c.
125. 375. 1125, &c.
625. 1875, &c.
&c.

The numbers of which being doubled as often as poſſible within the limit 2048, and collected and ranged in order with the powers of 2, will give the following numbers, 1. 2. 3. 4. 5. 6. 8. 9. 10. 12. 15. 16. 18. 20. 24. 25. 27. 30, &c. as in the following table.

TABLE

TABLE of *musical* numbers, contained in eleven octaves.

Num.	Chord Asc.	Chord Desc.	Num.	Chord Asc.	Chord Desc.	Num.	Chord Asc.	Chord Desc.
2	F♭	B♭	144	G♭	A♭	750	B♯	F♭
3	F♭	B♭	150	G♯	A♭	768	B	E
4	C	E	160	A	G	800	C♯	E♭
5	F♭	B♭	162	A	G	810	C♯	E♭
6	A	G	180	B	F	864	D	D
8	C	E	192	C	E♭	900	D♯	D
9	F♭	B♭	200	C♯	E♭	960	E	C
10	G	A	216	D	D	972	E	C
12	A	G	225	D♯	D	1000	E♯	C
15	C	E	240	E	C	1024	F♭♭	B♭♭
16	E	C	243	E	C	1080	F♯	B♭
18	F♭	B♭	250	E♯	C	1125	F♯	B♭
20	G	A	256	F♭	B♭	1152	G	A
24	A	G	270	F♯	B♭	1200	G♯	A
25	C	E	288	G	A	1215	G♯	A
27	C♭	E♭	300	G♯	A	1250	G♯	A
30	D	D	320	A	G	1280	A	G
32	E	C	324	A	G	1296	A	G
36	F♭	B♭	360	B	F	1350	A♯	G
40	G	A	375	B♯	F	1440	B	F
45	A	G	384	C	E	1458	B	F
48	B	E	400	C♯	E♭	1500	B♯	F
50	C♯	E♭	405	C♯	E	1536	C	E
54	D	D	432	D	D	1600	C♯	E♭
60	E	C	450	D♯	D	1620	C♯	E♭
64	F♭	B♭	480	E	C	1728	D	D
72	G	A	486	E	C	1800	D♯	D
75	G♯	A	500	E♯	C	1875	D♯	D
80	A	G	512	F♭	B♭	1920	E	C
81	A	G	540	F♯	B♭	1944	E	C
90	B	E	576	G	A	2000	E♯	C
96	C	E	600	G♯	A	2025	E♯	C
100	C♯	E♭	625	G♯	A♭♭	2048	F♭♭	B♭♭
108	D	D	640	A	G			
120	E	C	648	A	G			
125	E♯	C	675	A♯	F			
128	F♭	B♭	720	B	F			
135	F♯	B♭	729	B	F			

To understand this table it is to be observed, that by dividing a given stretched string or chord, by means of a moveable bridge, the sounds produced by its parts will be higher in pitch than those produced by the given chord. And, on the contrary, if we multiply a chord, that is, by a moveable bridge lengthen the sounding part of a chord, we shall have sounds lower in pitch than the given chord. Hence we have the foundation of an ascending, and of a descending scale of *musical* sounds. The first column of each division of the table, marked *Num.* expresses the musical numbers; the second column, marked *Asc.* the names of the notes in the ascending scale; and the third column, marked *Desc.* the names of the notes of the descending scale. Thus if the given chord be unity, and called F, then will 15 be E in the fourth octave ascending of F; 45 will be B in the sixth octave of F, &c. In the descending scale unity will be B; 15 will be C in the fourth octave descending from B; and 45 will be F of the fifth octave, &c.

The reason why unity is marked F in the ascending scale, and B in the descending scale, is, because, according to the received notation of what is called the natural scale among musicians, F has no fourth in ascending, nor B a fourth in descending. Now it is plain that no aliquot division of a string can give a fourth, or any of its octaves ascending; nor can any multiple of a string give the fourth, or any of its octaves, in descending. For the fourth being expressed by $\frac{3}{4}$ in ascending, and by $\frac{4}{3}$ in descending, its octaves will be $\frac{3}{8}$, $\frac{3}{16}$, $\frac{3}{32}$, &c. in the first case, and $\frac{8}{3}$, $\frac{16}{3}$, $\frac{32}{3}$, &c. in the second case, none of which numbers can be multiples, or submultiples of a given string.

F and B being the given sounds, their octaves will be expressed by F', F'', F''', &c. and B', B'', B''', &c. which are, respectively, the first, second, and third octaves, above the F, and below B.

A dot marked over a letter shews that it signifies a sound higher by a comma than the sound expressed by the letter itself. And a dot placed below, denotes the sound to be lowered by a comma. Thus, in the table I find 81 to be A | G, which denotes that A, or the sharp in the seventh octave of F, ascending, is raised a comma; and that G, or the sharp third from B, descending, is lowered by the same interval.

If B in the descending scale be supposed to be a tritonus, that is, two tones major, and one tone minor above F of the ascending scale, then will A in one of these scales correspond or be denoted by the same numbers with G in the other scale; and C will correspond to E, but D in the ascending scale will not be expressed by the same numbers as in the descending scale: for in the former D will be a tone major above C, whereas in the latter D must by analogy be a tone major below E, and therefore only a tone minor above C, which is the reason why *D* is in *smaller* in the descending scale.

Mr. Henfling has mentioned the distinction between an ascending and a descending scale in the Miscel. Berolinens. He places unity in the ascending scale in F, as it ought; but in the descending scale he places unity in E, which disturbs the analogy of the two scales.

The trumpet and French horn, not having (commonly) a compass beyond four octaves; and their sounds being formed in a manner analogous to those produced by the division of a string, it follows, that all the true notes of these instruments will be represented by the musical numbers 1, 2, 3, 4, 5, 6, 8, 9, 10, 12, 15, 16, &c. This is a fact well known; and a confirmation of the truth of that theory which derives all musical proportions from the elements 2, 3, and 5. Phil. Trans. N° 195, and N° 481. See TRUMPET.

MUSICAL *proportion*. See PROPORTION.

MUSICAL *sound*. See SOUND.

MUSICAL *string*. See STRING.

MUSIMON, in *Natural History*, the name of an animal esteemed a species of sheep, described by the ancients as common in Corsica, Sardinia, Barbary, and the northeast parts of Asia. It has been suspected, whether the animal described under this name is now any where to be found in the world; not that it is to be supposed that any species of animal once created is become extinct, but that this probably was a spurious breed between two animals of different species, perhaps the sheep and goat, which, like the mule, not being able to propagate its species, the production of them may have been discontinued.

Belon styles this species of GOAT, which has large horns bending back, close at their base, distant at their points, with circular rugæ, the TRAGELAPHUS, from the mixture it seems to have of the goat and deer. Buffon supposes it to be the sheep in a wild state; and as such, described by Mr. Pennant. These animals live in the mountains, and run with great swiftness among the rocks. Those of Kamtschatka are so strong, that ten men can scarce hold one; and the horns are so large as sometimes to weigh thirty pounds, and so capacious, that young foxes often shelter themselves in the hollow of such as by accident fall off in the deserts.

MUSIVUM *argentum*. See ARGENTUM.

MUSK, *moschus*, derived from the Arabic *moscha*, *musk*; whence was formed the common Greek μοσχος, *mosch*, a kind of perfume, of a very strong scent; only agreeable when moderated by the mixture of some other perfume. *Musk* is found in a kind of bag, or tumour, growing about the bigness of a hen's egg under the belly, towards the genital parts of a wild beast of the same name; and appears to be nothing else but a kind of bilious blood there congealed, and almost corrupted.

The animal which produces it is pretty common in the kingdom of Bantan, Tonquin, and some others, as Cochin-China, &c. But the most esteemed are those in the kingdom of Tibet. See MOSCHIFERUM *animal*.

They inhabit the woods and forests, where the natives hunt them down: when the beast is killed, they cut out the bladder under the belly, separate the coagulated blood, and dry it in the sun, where it is reduced into a light friable substance almost of the nature of a powder, and of a dusky reddish colour, and acquires a very strong and disagreeable smell. It is then tied up again in bladders, and exported to other countries; and this is the *musk* which we use.

The *musk* itself is dry, with a kind of unctuosity; of a dark reddish brown, or rusty blackish colour; in small round grains, with very few hard black clots; perfectly free from any sandy, or other visible foreign matter. Chewed, and rubbed on paper, it looks bright, yellowish, smooth, and free from grittiness. Laid on a red-hot iron it catches flame, and burns almost entirely away, leaving only an exceeding small quantity of light greyish ashes: if any earthy substances have been mixed with the *musk*, the quantity of the residuum will discover them. From thirty grains of *musk*, water extracts twelve grains, and spirit of wine ten grains. Spirit of nitre and oil of vitriol totally dissolve it: the former destroys the whole

of

of its ſmell, and the latter the greateſt part of it. Spirit of ſalt, diluted ſpirit of vitriol, and vinegar, have no effect upon it. Spirit of ſal ammoniac diſſolves a little of it. Oil of tartar ſcarce acquires any tinge from *muſk*, but extricates from it a volatile urinous ſmell. *Muſk* is not ſoluble in oils expreſſed or diſtilled. By diſtillation in a retort, it yields the animal principles, empyreumatic oil, volatile ſpirit, and ſalt. In the diſtillation of odoriferous waters and ſpirit, a ſmall portion of *muſk*, included in a linen cloth, is generally hung in a ſtill-head, the vapour of both liquors extracting its ſcent. Spirit, diſtilled with *muſk* immerſed in it, acquires little of its ſmell; but water by this method acquires both the ſmell and taſte. A minute portion of *muſk* greatly improves the fragrance of the diſtilled odoriferous waters, as thoſe of lavender and roſemary, and heightens the ſmell of other odoriferous ingredients, without communicating any of its own peculiar ſmell. The quantity of liquor, which may be flavoured by macerating a certain known proportion of *muſk* for a few days in rectified ſpirit of wine, appears to be the beſt criterion of the genuineneſs and goodneſs of this commodity; a commodity, which is not only ſaid to vary according to the ſeaſon of its being taken from the animal, but which is oftentimes ſo artfully ſophiſticated, that the abuſes cannot be diſcovered by any external characters, or by any other means than the degree of its ſpecific ſmell and taſte, which the above experiment affords the beſt method of eſtimating. Neumann and Lewis.

What the ancients have written of *muſk* is fabulous, viz. that it comes from the teſticles of a caſtor, which, to ſtop the purſuit of the hunter, caſtrates itſelf. The occaſion of their error may be owing to this, that among the Indians the *muſk* animal goes by the name of *caſtor*.

Muſk is in conſiderable uſe among the perfumers and confectioners, though much leſs now than it was formerly. It is ſuppoſed to fortify the heart and brain, and is good againſt deafneſs, and is now received in general practice in different convulſive diſorders; and its doſe has been increaſed with advantage to a ſcruple and half a dram, every four or ſix hours.

Muſk, and other perfumes of the ſame tribe, have been long celebrated as antiſpaſmodics, but were formerly ordered in ſuch ſmall quantities as to have little effect. Practitioners thought four or five grains a large doſe. But the Chineſe have taught us to be more bold; the tenth part of an ounce is an uſual doſe among them. The remedy in the Eaſt for the bite of the mad dog contains ſixteen grains of *muſk*, and this they repeat frequently. See MADNESS.

The effects of *muſk* are, eaſe from pain, quiet ſleep, and a copious diaphoreſis. Hence it has been found of great uſe in ſpaſmodic diſorders, petechial, malignant, putrid fevers, the gaol diſtemper, hiccoughs, *ſubſultus tendinum*, &c. For the particular caſes, we refer to the Philoſophical Tranſactions, N° 474. § 18. and vol. xliv. p. 75, &c. Inſtances occur in which it has been of very great benefit in convulſive diſorders, in the London Med. Obſ. &c. vol. iii. art. 24. 31.

It has alſo been found uſeful in ſpaſmodic diſorders, given by way of clyſter, as Dr. Wall obſerves, in that Tranſaction.

The operation of *muſk*, in ſome reſpects, reſembles that of opium; but is in this much preferable, that it does not leave behind it any ſtupor or languidneſs, which the latter often does. *Muſk* therefore ſeems likely to anſwer in thoſe low caſes where ſleep is much wanted, and opiates are improper.

It is ſaid to be beſt given in a bolus, and that thoſe who are moſt averſe to perfumes may take it in that form without inconvenience. For, as Etmuller, and others, have long ago obſerved, the ſmell of the perfume is often found to be of diſſervice, where the ſubſtance inwardly taken produces good effects.

It is pity that a medicine of this conſequence ſhould be ſo liable to adulterations, and that the criteria of its genuineneſs are ill ſettled.

In a paper read before the Royal Society, March 17, 1747-8, ſeveral cures performed by *muſk*, on diſtempered cows, were mentioned.

When *muſk* begins to decay, it is a practice uſed in the Eaſt Indies to put it into a bladder or bag, wherein many ſmall holes are made with a needle, and hang it in a neceſſary-houſe, but not low enough to touch the filth. Others keep it wrapped up in linen, well moiſtened with rank urine.

Mr. Boyle ſays, of his own knowledge, that *muſk* has greatly contributed to the preſervation of fleſh. Works abr. vol. i. p. 30.

MUSK-*ant*. See ANT.

MUSK-*boar*, in *Zoology*. See TAJACU.

MUSK *hyacinth*. See HYACINTH.

MUSK-*inſect*. See INSECT.

MUSK *julep*. See JULEP.

MUSK-*rat*. See RAT.

MUSK-*ſeed*, in the *Materia Medica*, the name of the ſeed of the *alcea Ægyptiaca villoſa*, or hoary Egyptian vervain mallow. See *Syrian* MALLOW.

It is a ſmall ſeed of about the bigneſs of a pin's head, of a greyiſh brown in colour, and of the ſhape of a kidney, and when freſh it has a perfumed ſmell. It is brought into Europe from Egypt, and from Martinico. The Egyptians uſe it internally as a cordial and provocative; but in Europe it is of very little uſe, being wholly neglected in medicine; but the perfumers in France and Italy uſe it among their compoſitions.

MUSKET, or MUSQUET, properly a fire-arm borne on the ſhoulder, and uſed in war; to be fired by the application of a lighted match.

The length of the *muſket* is fixed to three feet eight inches from the muzzle to the touch-pan, and its bore is to be ſuch as may receive a bullet of fourteen in a pound, and its diameter differs not above one fiftieth part from that of the BULLET.

Muſkets were anciently borne in the field by the infantry, and were uſed in England ſo lately as the beginning of the civil wars. At preſent they are little uſed, except in the defence of places; fuſees, or FIRE-*locks*, having taken their place and name.

MUSKET-*baſkets*, in *Fortification*. See BASKETS.

MUSKETEERS, ſoldiers armed with muſkets.

MUSKETOON, a muſket ſhorter, though thicker, than the ordinary muſkets. It is fired by the collision of a ſteel and flint in the lock; whereas the muſket is fired by a match. Its bore is a thirty-eighth part of its length, and carries five ounces of iron, or ſeven and a half of lead, with an equal quantity of powder. This is the ſhorteſt ſort of blunderbuſſes. See FIRE-*lock*.

MUSLIN, or MUSSELIN, a fine ſort of cloth, wholly cotton; ſo called, as not being bare, but having a downy knap on its ſurface reſembling moſs, which the French call *mouſſe*.

There are various kinds of *muſlins* brought from the Eaſt Indies, chiefly Bengal; beteilles, tarnatans, mulmuls, tanjebs, terrindams, doreas, &c.

Muſlins, on their importation, pay a duty of 2*l.* 10*s.* 7*d.* the piece, which is drawn back on exportation; and beſides this a duty of 15*l. per cent.* to be computed according to the groſs price at which they are publicly ſold by auction; but if they are exported, all drawn back is for 20*s.* value.

MUSQUETEERS, *mouſquetaires*, in France, are troopers who fight ſometimes on foot, ſometimes on horſeback; they are gentlemen of good families, and are divided into two troops, the one called the grey *mouſquetaires*, the other the black *mouſquetaires*, from the colour of their horſes.

MUSSA *mura*. See MOOR.

MUSSAHIR, in *Ornithology*, a bird mentioned by Arabian writers. It is ſaid that this creature, after having employed the day in ſeeking its food, ſpends the whole night in ſinging; its notes are ſaid to be ſo melodious, as to baniſh all thoughts of ſleep from thoſe that hear them.

MUSSLIN. See MUSLIN.

MUSSULMAN, or MUSULMAN, written in Arabic *muſlem*, *muſleman*, or *muſulman*, a title by which the Mahometans diſtinguiſh themſelves; ſignifying, in the Turkiſh language, *true believers*, or *orthodox*.

The appellation was firſt given to the Saracens; as is obſerved by Leunclavius. There are two kinds of *muſſulmani*, very averſe to each other; the one called *Sonnites*, and the other *Shiites*. The Sonnites follow the interpretation of the Coran given by Omar; the Shiites are the followers of Ali. The ſubjects of the king of Perſia are Shiites; and thoſe of the grand ſignior, Sonnites. See SONNA, and ALCORAN.

Some authors will have it, that the word *muſſulman* ſignifies *ſaved*, that is, predeſtinated; and that the Mahometans give themſelves the appellation, as believing they are all predeſtinated to ſalvation. Marmins is more particular as to the origin of the name; which he derives from the Arabic מסלם *muſalam*, *ſaved*, *ſnatched out of danger*: the Mahometans, he obſerves, eſtabliſhing their religion by fire and ſword, maſſacred all thoſe who would not embrace it, and granted life to all that did, calling them *muſſulmans*; q. d. *erepti e periculo*; whence the word, in courſe of time, became the diſtinguiſhing title of all thoſe of that ſect, who have aſſixed to it the ſignification of *true believer*.

MUST, *muſtum*, ſweet wine newly preſſed from the grape; or the new liquor preſſed from the fruit before it has worked or fermented.

MUST of *Rheniſh wine*. This is a liquor that, though drank by ſome, is found extremely to affect the brain; for not having paſſed the natural effervеſcence which it would have been ſubject to, in the making of wine, its

falts are locked up till the heat of the ſtomach ſetting them to work, they raiſe their effervescence there, and ſend up abundance of ſubtile vapours to the brain. The Rheniſh *muſt* is of two kinds, being made either with or without boiling. That made without boiling is only put up ſo cloſe in the veſſel, that it cannot work; this is called ſtumm-wine. That by boiling is thus prepared: they take ſtrong veſſels not quite filled, and putting them into a cellar they make a fire mild at firſt, but increaſed by degrees, and afterwards they gradually leſſen it again, that the boiling may ceaſe of itſelf. This operation is finiſhed in thirty-ſix or forty hours, according to the ſize of the veſſel; and the wine-boilers, inſtead of common candles, which would melt by the heat, uſe thin pieces of ſplit beech-wood. Theſe alſo ſerve for a double purpoſe, not only lighting them, but giving them notice of the boiling being enough; before that time, the quantity of vapours thrown up make them burn dim; but as ſoon as it is finiſhed, the vapours aſcend in leſs quantity, and the lights burn brisk and clear. About ſeven or eight days after this boiling, the *muſt* begins to work, and after this working it is called wine. They have alſo another kind of Rheniſh *muſt*, which is thus prepared: they boil the liquor to half the quantity, and put into it the medicinal ingredients they are moſt fond of; ſuch as orange-peel, elecampane-root, and juniper-berries, or the like; being thus medicated, the whole works much more ſlowly than it otherwiſe would. If the boiled *muſt* by too violent an effervescence caſt out its lees, it will on this become vapid and dead, unleſs this ſeparation is ſtopped by ſome fatty ſubſtance, ſuch as freſh butter or the like: they put this in upon a vine leaf, or elſe apply lard to the mouth of the veſſel.

A MUST *for artificial wine* may be thus made: take twenty pounds of fine ſugar, five gallons of water, four ounces of white tartar finely pulveriſed, or cream of tartar, and boil them in a large veſſel over a gentle fire.

MUSTACEUM, among the ancient Romans, a kind of cheeſe-cake. It was compoſed of cheeſe, aniſeed, cummin, and fuet added to flour, moiſtened with *muſtum*, or new wine.

MUSTARD, *ſinapi*, in *Botany*, a genus of the *tetradynamia ſiliquoſa* claſs. Its characters are theſe: the empalement of the flower is compoſed of four narrow leaves, placed in form of a croſs, which fall off; the flower has four roundiſh petals in form of a croſs, and four oval nectariums, one on each ſide of the ſtamina and the pointal; it has ſix awl-ſhaped erect ſtamina, two of which are oppoſite and as long as the empalement, the other four are longer; in the center is placed a taper germen, with a ſtyle the length of it, crowned by a headed ſtigma; the germen afterwards turns to an oblong pod, which is very rough at bottom, having two cells, opening with two valves, whoſe intermediate partition is large, compreſſed, and almoſt twice the length of the valves; the ſeeds are globular. Miller reckons ſix, and Linnæus twelve ſpecies.

The firſt ſort is the common white *muſtard*, which is generally cultivated as a ſallad herb for winter and ſpring uſe. The ſeeds of this are commonly ſown very thick in drills, either upon a warm border, or in very cold weather upon a moderate hot-bed, with creſſes and other ſmall ſallad herbs, which are commonly fit for uſe in ten days or a fortnight from the time of ſowing; for if they are large, and have rough leaves, they are too ſtrong to put into ſallads.

The ſecond ſort is the common *muſtard*, which is frequently found growing naturally in many parts of England, but is alſo cultivated in fields for the ſeed, of which the ſauce called *muſtard* is made. This ſort is cultivated only for the ſeeds; theſe ſhould be ſown in the ſame way as thoſe of the firſt, and the plants treated in the ſame manner; with this difference, of allowing the plants twice as much room, becauſe they grow much larger; ſo theſe ſhould be hoed out to the diſtance of eighteen inches; and as the ſeeds will not ripen ſo ſoon as the other, ſo the ground may require to be hoed three times over, but that may be eaſily ſeen by the growth of the weeds. The ſeeds of theſe two firſt ſpecies are ordered for medicinal uſe.

Muſtard ſeed is one of the ſtrongeſt of the pungent, ſtimulating, diuretic medicines, that operate without exciting much heat. It is ſometimes taken unbruiſed, to the quantity of a ſpoonful at a time, in paralytic, cachectic, and ſerous diſorders. It is applied alſo as an external ſtimulant, to benumbed and paralytic limbs; to parts affected with fixed rheumatic pains; and to the ſoles of the feet, in the low ſtage of acute diſeaſes, for raiſing the pulſe: in this intention, a mixture of equal parts of the powdered ſeeds and crumb of bread, with the addition, ſometimes, of a little bruiſed garlic, are made into a cataplaſm, with a ſufficient quantity of vinegar. See SINAPISM.

Muſtard ſeed yields upon expreſſion a conſiderable quantity of oil, which is by ſome recommended externally againſt rheumatiſms and palſies, though it has nothing of that quality by which the ſeeds themſelves prove uſeful in thoſe diſorders; the oil being mild and inſipid as that of olives, and the pungency of the ſeed remaining entire in the cake left after expreſſion; nor is any conſiderable part of the pungent matter extracted by rectified ſpirit. The bruiſed ſeeds give out readily to water nearly the whole of their active matter: added to boiling milk they curdle it, and communicate their pungency to the whey. The powder of *muſtard* ſeed may be made into the conſiſtence of a loch with warm water, in which a little ſea ſalt has been diſſolved. Of this a common ſpoonful, ſometimes two, diluted with tepid water, are given on an empty ſtomach; it operates well as an emetic, and proves an excellent remedy in moſt nervous diſorders, according to Mr. Monro, in Med. Eſſ. Edinb. vol. ii. art. 19. p. 303. not.

The third ſort grows naturally on arable land, in many parts of England. The ſeed of this is commonly ſold under the title of Durham *muſtard* ſeed. This is a common weed in moſt parts of England; and comes up early in the ſpring amongſt the corn, ſo flowers and ſeeds in May; therefore where it is not weeded out, the ſeeds will ſcatter long before the corn is ripe, and the ground will be ſtocked with the weed. The other three ſorts are preſerved in botanic gardens for variety, but are never cultivated for uſe; theſe may be treated in the ſame way as the two firſt ſpecies. Miller and Lewis.

MUSTARD, *baſtard*, in *Botany*. See CLYOME.

MUSTARD, *hackle*, or *baſtard mithridate muſtard*, *biſcutella*, in *Botany*, a genus of the *tetradynamia ſiliculoſa* claſs of plants. Its characters are theſe: the empalement of the flower is compoſed of four leaves, which are pointed; the flower hath four petals, placed in form of a croſs, which are obtuſe and ſpread open: it hath ſix ſtamina, four long and two ſhort; in the center is ſituated an orbicular compreſſed germen, which afterwards becomes a plain, compreſſed, erect, capſule, with two convex lobes, having two cells, terminated by the rigid ſtyle, which is joined to the ſide of the partition.—Linnæus reckons two, and Miller four ſpecies.

MUSTARD, *hedge*, *eryſimum*, in *Botany*, a genus of the *tetradynamia ſiliquoſa* claſs. Its characters are theſe: the empalement of the flower is compoſed of four oblong, oval, coloured leaves; the flower hath four petals placed in form of a croſs, and two nectarious glands ſituated between ſix ſtamina, four of which are the length of the empalement, the other two ſhorter; it hath a narrow four-cornered germen, which afterwards becomes a long, narrow, four-cornered pod, with two cells, filled with ſmall ſeeds. Linnæus reckons ſix, and Miller ſeven ſpecies.

The firſt ſort is uſed in medicine; it grows naturally on the ſide of foot-paths, and upon old walls in moſt parts of England, ſo is rarely cultivated in gardens; where, if it was once admitted, it would become a troubleſome weed. The ſecond and third ſorts alſo grow naturally on banks in many parts of England; they were formerly eaten in winter ſallads, before the Engliſh gardens were furniſhed with better plants; ſince which time they have been rejected, for they have a rank ſmell and are diſagreeable to the palate. The ſixth ſort grows naturally on the ſides of banks in many parts of England, ſo it is not ſuffered to have a place in gardens. This was formerly eaten as a ſallad herb by the poorer ſort of people, who gave it the title of ſauce alone. It hath a rank ſmell, and taſte of garlic, is very biting and hot on the palate; it is frequently preſcribed in medicine. The ſeventh ſort, called gilliflower with a dame's violet leaf, is ſometimes found growing naturally on old walls, in ſome parts of England, particularly about Cambridge and Ely. The other ſorts are kept in botanic gardens for variety.

Hedge muſtard is hot and dry, opening and attenuating, and by its warming quality is good to diſſolve thick, groſs, ſlimy humours of the lungs, to help a cough and ſhortneſs of breath, and is particularly recommended againſt an habitual hoarſeneſs, to recover a voice. Riverius praiſes a decoction of it in wine againſt the colic.

The only official preparation of this plant is the *ſyrupus de eryſimo*. It is recommended, by Dr. Stahl, for ſchirrocancrous tumours, taken internally, and alſo applied externally to the tumor. We have an account of its good effects, by Monſ. Bingert, in Art. Med. Berol. Dec. 3. vol. i. p. 59.

The ſeeds are conſiderably pungent, and appear to be of the ſame quality with thoſe of *muſtard*, but weaker.

MUSTARD, *mithridate*. See TREACLE *muſtard*.

MUSTARD, *rough podded*. See SYSIMBRIUM.

MUSTARD, *tower*, *turritis*, in *Botany*, a genus of the *tetradynamia ſiliquoſa* claſs. Its characters are theſe: the em-

palement of the flower is compoſed of four oblong oval leaves, which cloſe together; the flower has four oblong, oval, entire petals, in form of a croſs, and ſix erect awl-ſhaped ſtamina, the length of the tube, two of which are ſhorter than the other, terminated by ſingle ſummits, and a taper germen, a little compreſſed, having no ſtyle, but crowned by an obtuſe ſtigma: the germen afterward becomes a long four-cornered pod with two cells, which are divided by no intermediate partition, opening with two valves, and filled with ſmall, roundiſh, indented ſeed. Miller enumerates two, and Linnæus three ſpecies.

Theſe plants are kept in botanic gardens, for variety; but if their ſeeds are ſcattered upon an old wall or building, in autumn, ſoon after they are ripe, the plants will come up, and thrive without farther care, and their ſeeds will ſcatter on the wall and ſpread, ſo there will be no danger of the plants maintaining their ſituation, if they are not purpoſely deſtroyed.

The juice of this plant is recommended by ſome for curing ulcers in the mouth, and for killing worms.

MUSTARD, *baſtard tower-muſtard*, in *Botany*, a genus of the *tetradynamia ſiliculoſa* claſs. Its characters are theſe: the flower, which hath a four-leaved empalement, hath four petals in form of a croſs; at the bottom of each is ſituated a reflexed nectarium fixed to the empalement, and between theſe ariſe ſix upright ſtamina, two of which are no longer than the flower-cup, the other four are much longer; in the center is ſituated a taper germen, as long as the ſtamina, which becomes a narrow, long, compreſſed pod, opening length ways, having two valves and a thin partition, between which is lodged a row of flat ſeeds. Miller reckons four, and Linnæus nine ſpecies.

MUSTARD, *treacle*. See TREACLE *muſtard*, and CLYPEOLA.

MUSTELA, the *weaſel*, in the Linnean ſyſtem of *Zoology*, is a diſtinct genus of quadrupeds, of the order of *feræ*, in the claſs of *mammalia*, comprehending eleven ſpecies; viz. the ferret, polecat, ermin, otter, glutton, martin, &c.

The characters of this genus are, that it has ſix cutting teeth in each jaw; the upper are erect, acute, and ſeparate; the lower are more obtuſe, and the tongue is ſmooth. See *Tab.* III. *Quadrupeds*, N° 39. See WEASEL.

MUSTELA *Africana*, in *Zoology*, a name by which Cluſius has called an animal, properly of the ſquirrel kind, and known among others by the name of the Barbary ſquirrel.

MUSTELA, in *Ichthyology*, the name of a genus of fiſhes, of which there are ſeveral ſpecies; the moſt common of which is that called the *ſea-loche*, or whiſſle-fiſh. This reſembles the common eel, in figure, colour, and ſlipperyneſs to the touch; but is not half ſo long, in proportion to its thickneſs; and is ſomewhat flatter, and has a turgid belly. It is covered with extremely minute ſcales, and its mouth is large, and furniſhed with ſharp teeth, and has ſeveral ſeries of very ſmall teeth in many parts of its mouth; at the angle of the lower jaw it has one beard, and at the upper part of the noſtrils in the upper jaw it has two; it has two pair of fins under its belly, and on the back, beſide the common fin reaching half the length and almoſt to the tail; it has at ſome ſmall diſtance from the head a cavity in which is a membrane edged with filaments.

The different ſpecies of this fiſh are of three colours; one is not ſpotted, and of the colour of a tench; another is ſpotted with white; and the third with reddiſh black ſpots; and beſide theſe there are the *muſtela viviparus* of Schonfeldt, commonly known by the name of *aelyuappe*, and the *muſtela foſſilis*, called *peiſker*, and the *eel-pout*. All which ſee under their ſeveral heads.

MUSTELA *fluviatilis*, in *Ichthyology*, a name by which ſeveral authors have called the common *lampetra* or *lamprey*.

MUSTELA *lumpen*, in *Ichthyology*, a name given by Artedi, from Ray and others, to that ſpecies of blennus, called ſimply *lumpen* at Antwerp, and by Geſner *galea*.

It is diſtinguiſhed, by Artedi, from the other blenni, by a ſpecific name, expreſſing that it has four bifid cirri or beards growing under the throat, and tranſverſe arcolæ or ſtreaks on the back. See BLENNUS.

MUSTELA *marina*, in *Ichthyology*, a name given by Bellonius and others to that fiſh which we call in Engliſh the *ſhoat-fiſh*, the *glanus* and *glanis* of Pliny and the old authors.

It is diſtinguiſhed, by Artedi, by the name of the *ſilurus*, with four beards near the mouth. By this character it is evidently diſtinguiſhed from the fiſh called the *lake*, which, though a genuine ſpecies of ſilurus, has only one beard.

MUSTELINUM *genus*, in *Zoology*, the name of a claſs of animals, ſo called from their general likeneſs to the weaſel in ſhape; they are all carnivorous animals, and are diſtinguiſhed from the other quadrupeds of that ſort by their ſmallneſs, the length of their bodies, and the ſmallneſs and narrowneſs of their heads. Their feet are ſmall, and their legs ſhort, whence they are formed for running into holes and crannies; their teeth are leſs numerous than in many quadrupeds; in the dog-kind there are forty, and in theſe but thirty-two. Their inteſtines are ſhort and ſimple; they have no colon nor cæcum, nor any diſtinction of great and ſmall guts. Ray.

MUSTELUS, in *Ichthyology*, a name given by Gaza, and ſome other writers, to the fiſh called GALEUS *aſterias*, and *ſtellaris* by modern authors. This only accidentally differs from the common *galeus lævis*, the ſmooth or unprickly hound. Both are accounted the ſame ſpecies, by Artedi, and are expreſſed by the ſame name, the SQUALUS with obtuſe or glandulous teeth.

MUSTELUS *lævis*, a name by which Aldrovandus, and ſome others have called the fiſh, diſtinguiſhed by others by the name of GALEUS *lævis*, the ſmooth hound-fiſh.

MUSTELUS *lævis*, in *Ichthyology*, a name of a kind of ſhark, called alſo the CANIS *galeus*, and *canſa*.

MUSTER, a review of a body of military forces under arms, in order to take account of the numbers, condition, accoutrements, arms, &c.

The word is formed of the French, *monſtre*, *ſpecimen*. See REVIEW.

MUSTER, *falſe*. See FALSE.

MUSTER-*maſter-general*, or *Commiſſary-general of* MUSTERS, is an officer in the army, who takes account of every regiment, their number, horſes, arms, &c. See COMMISSARY.

MUSTER *rolls* are liſts of the ſoldiers in every troop, company, regiment, &c. delivered by the captains to the commiſſary: by which they are paid, and the ſtrength of the regiment known.

MUSTERED *of record* (Stat. 18. Hen. VI.) denotes a being inrolled in the number of the king's ſoldiers.

MUSTERING, in *Sea Language*, is the act of calling over a liſt of the whole ſhip's company, or any particular detachment thereof, who are accordingly ſummoned to anſwer by their names on the occaſion.

MUSTUS *fluviatilis*, in *Ichthyology*, a name given by Bellonius to that ſpecies of CYPRINUS which we know by the name of the barbel.

MUSTUS is alſo a word uſed by ſome authors to expreſs the white eaſs of urine.

MUTABILIS *lapis*, in *Natural Hiſtory*, a name given by ſome to the ſemi-pellucid gem, more commonly called OCULUS *mundi*.

MUTABILITY is oppoſed to IMMUTABILITY.

MUTARE *arma*. See ARMA.

MUTATION, the act of changing, or ſometimes the change itſelf.

It is one of the laws of nature, that the *mutation* of motion is ever proportional to the moving force impreſſed. See NATURE, and MOTION.

MUTATION, in the *Ancient Muſic*, is applied to the changes or alterations that happen in the order of the ſounds which compoſe the melody.

Ariſtoxenus repreſents *mutation* as a kind of paſſion in the order of the melody.

The changes are, 1. in the genera; when the ſong begins in one, as the chromatic, and paſſes into another, as the diatonic. 2. In the ſyſtem; as when the ſong paſſes out of one tetrachord, as meſon, into another, as diezeugmenon; or more generally, when it paſſes from a high place of the ſcale to a lower, or contrarily, i. e. part of it is ſung high, and part low. 3. In the mode or tone, as when the ſong begins in one, as the Doric, and paſſes into another, as the Lydian. 4. In the melopœia, that is, when the ſong changes the very air, ſo as from gay and ſprightly to become ſoft and languiſhing, or from a manner that expreſſes one paſſion or ſubject to the expreſſion of ſome other.

MUTATIONES, among the Romans, poſt ſtages, or places where the public couriers were ſupplied with freſh horſes.

The *mutationes* were wholly deſigned for the uſe of theſe couriers, or meſſengers of ſtate; in which reſpect they differed from *manſiones*.

MUTCHKIN, a liquid meaſure uſed in Scotland; it contains four gills, and is the fourth part of a Scotch pint. See PINT, MEASURE, &c.

MUTE, *dumb*, denotes a perſon that cannot ſpeak, or has not the uſe of ſpeech.

Mutes and dwarfs make their fortune in the grand ſignor's ſeraglio. The *mutes* ſerve as executioners to take off perſons of the firſt rank.

MUTE, in *Law*, a perſon that ſtands dumb or ſpeechleſs, when he ought to anſwer or plead.

A prisoner may stand *mute*, two ways. 1. When he speaks not at all: in which case it is inquired, whether he stand *mute* of malice, or by the act of God; if by the latter, then the judge, *ex officio*, ought to inquire whether he be the same person; and of all other pleas, which he might have pleaded if he had not stood *mute*. 2. When he pleads not directly, or will not put himself upon the inquest to be tried. If he be found to be obstinately *mute*, then, if it be on an indictment of high treason, it is clearly settled that standing *mute* is equivalent to a conviction; and he shall receive the same judgment and execution. So likewise, in petit larceny, and in all misdemeanors, standing *mute* is equivalent to conviction. But in appeals or indictments for other felonies, or petit treason, it was the custom till of late not to consider him as convicted, so as to pass judgment for the felony; but for his obstinacy he was to receive the terrible sentence of penance, or PEINE *forte et dure*. Before this was pronounced, the prisoner was allowed not only *tribus admonitis*, but also a convenient respite for a few hours, and the sentence was distinctly read to him, that he might know his danger; and, after all, if he continued obstinate, and his offence was clergyable, he was allowed the benefit of his clergy, even though he is too stubborn to pray it. But in this respect the law is now altered; for by 12 Geo. III. cap. 20. standing *mute* in felony or piracy is made a conviction.

To advise a prisoner to stand *mute* is an high misprision, a contempt of the king's court, and punishable by fine and imprisonment.

MUTE, in *Grammar*, a letter which is not sounded, or heard in the pronunciation; or a letter which yields no sound of itself, and without a vowel.

The consonants are ordinarily distinguished into *mutes*, and *liquids* or semi-vowels. See CONSONANT, LIQUID, &c.

The *mutes* in the English alphabet are eleven; viz. B, C, D, F, G, J, K, P, Q, T, V. They are called *mutes*, because a liquid cannot be sounded in the same syllable before them, as ra, ro; but a *mute* may be pronounced in the same syllable before a liquid, as bra.

MUTEFERRIRA, a body of horse kept up in Egypt, for the service of the grand signor; these, with the chaouses, were originally the guards of the sultans of Egypt. This is a body of the greatest dignity, and is expressed by the word which signifies a chosen people.

MUTILATED *corniche*. See CORNICHE.

MUTILATED *medals*. See MEDAL.

MUTILATED *roof*. See ROOF.

MUTILATION, the retrenching, or cutting away, any member of the body. See MAIM.

The use of the word is also extended to statues, and buildings, where any part is wanting, or the projecture of any member, as a cornice, or an impost, is broken off.

MUTILATION is sometimes also used in a more immediate manner, for CASTRATION.

MUTILLA, in the Linnæan system of *Natural History*, a genus of insects of the order of *hymenoptera*: the characters of which are, that in most there are no wings, that the body is covered with short hair or down, that the hinder part of the thorax is obtuse, and that the sting is hidden and pointed. Of this genus there are ten species.

MUTILUS, in *Natural History*, the name given by some to the common MUSCLE.

MUTINY, in a *Military Sense*, denotes an insurrection against authority.

An act is annually passed by parliament, called the *mutiny* act, to punish *mutiny* and desertion, and for the better payment of the army and their quarters.

This regulates the manner in which they are to be dispersed among the several inn-keepers and victuallers through the kingdom, and establishes a law martial for their government. By this, besides other things, it is enacted, that if any officer or soldier shall excite, or join any *mutiny*, or, knowing of it, shall not give notice to the commanding officer; or shall desert, or list in any other regiment, or sleep upon his post, or leave it before he is relieved, or hold correspondence with a rebel or an enemy, or strike or use violence to his superior officer, or shall disobey his lawful commands; such offender shall suffer such punishment as a court martial shall inflict, though it extend to death itself.

MUTU, in *Ornithology*, a name by which some call a large Brasilian bird, of the gallinaceous kind, more usually called MITU.

MUTUAL, a relative term, denoting something that is reciprocal between two or more persons.

Thus we say, *mutual assistance, mutual aversion, &c.*—There are *mutual* or reciprocal duties, offices, &c. between superiors and inferiors; as the king and his subjects, the master and his servants, &c.

Vangelas makes a distinction between *mutual* and *reciprocal*: *mutual*, according to him, is understood of what is between two only; and *reciprocal* of what is between more than two: but this distinction is little regarded in common use.

MUTUAL *testament* is that made by two persons who leave their effects reciprocally to the survivor.

MUTULE, *mutulus*, in *Architecture*, a kind of square modillion in the Doric frieze.

The chief difference between *mutule* and modillion consists in this, that the former is used in speaking of the Doric order, and the latter in the Corinthian, &c. See DORIC, &c.

The *mutules* in the Doric answer to the triglyphs, which are under them; whence some make *guttæ* or drops to hang.

Le Clerc makes *mutules* in the entablature of the Doric order, not only to distinguish it the more from other entablature, but also because they agree very well with the noblenels of this order, and add something of a masculine beauty to it.

Mutules are commonly made of the same breadth with the triglyphs; but the same author thinks it would be much better if they were made of the same breadth with the capitals of the triglyphs. Nor does he run his *mutules* so near the extremity of the larmier of drip, as is usually done; leaving a space of three or four minutes between the two, that the profile may appear the more distinctly.

MUTUUM, in the *Civil Law*, denotes a loan simply so called; or a contract introduced by the law of nations, whereby a thing consisting in weight, as suppose bullion; in number, as money; or in measure, as corn, timber, wine, &c. is given to another, upon condition that he shall return another thing of the same quantity, nature, and value, on demand.

This, therefore, is a contract without reward: so that where use or interest arises, there must be some particular article in the contract whereon it is founded.

MUZZLE *of a gun or mortar*, the extremity of the cylinder, where the powder and ball is put in. The metal which surrounds the extremity of the cylinder, is likewise called the *muzzle*.

MY.—*Per* MY *& per tout*. See PER *my*.

MYA, in *Natural History*, a genus of the *testacea* class of worms. Its characters are, that its animal is an *ascidia*, that it is a bivalve shell gaping at one end, and that the hinge for the most part is furnished with a thick, strong, and broad tooth, not inserted in the opposite valve.—Linnæus enumerates seven species. One of these is noted for producing great quantities of pearl: it is found in great rivers, especially in those which water the mountainous parts of Great Britain; and there have been regular fisheries for this shell in several of our rivers: sixteen have been found within one shell. They are said to be the disease of the fish, analogous to the stone in the human body. On being squeezed, they will eject the pearl, and often cast it spontaneously in the sand of the stream. The Conway was noted for them in the days of Camden: the Irt, in Cumberland, also produced them.

In the last century, several of great size were procured in the rivers of the counties of Tyrone and Donegal, in Ireland. Suetonius, Vit. Jul. Cæs. cap. 44. reports that Cæsar was induced to undertake his British expedition for the sake of our pearls: and we are told by Pliny and Tacitus, that he carried home a buckler made with British pearl, which he dedicated to, and hung up in the temple of Venus Genetrix.

MYAGRUM, in *Botany*. See GOLD *of pleasure*.

MYCETITES, in *Natural History*, the name of a species of sea-coral, which is usually of a conic shape and striated texture; always small, and usually found adhering to sea-shells, or large corals. See FUNGITE.

MYCETITES *difformis*, in *Natural History*, a name given by Dr. Woodward to those kinds of fossile coralloide bodies which the generality of writers had called, after Dr. Plot, *porpitæ*. These are usually small, and of roundish, but flatted figure; they are hollowed on one side with a sort of umbilicus, and striated on the other; they are found on the ploughed lands in Oxfordshire, and some other of our midland counties, and in other places, buried in the solid strata of stone; they are sometimes yellowish, sometimes brownish, and are from the breadth of an inch to a fourth part or less of that size; when broken, they are usually found to consist of a kind of spar, not unlike that of which the shelly coats of the echinitæ, or the lapides judici, and other spines of echini consist in their fossile state; and in some of them the ridges and striæ are thick set with little knobs and tubercles. The basis in some of these is flat, as it is in others rising in form of a circular elevation from the umbilicus, and others have

have a circular cavity in the same place. See *Tab. of Fossils*, class. 7.

MYCONOIDE, an epithet used by some chirurgical writers for some ulcers which are found continually filled with a thick mucous matter.

MYCTERIA, in *Ornithology*, a genus of the *grallæ*, of which there is one species, called by Marcgrave JABIRUGUACU.

MYDESIS, a word used by the ancient physicians to express a general corruption of any part, from a great redundance of moisture. Galen has appropriated it to the eye-lids.

MYDRIASIS, a name used by authors to express a disease of the eye, consisting in a dilatation of the pupil, and a consequent dimness of sight.

MYDROS, a word used by Hippocrates to express a ball of iron or stone, which was used to be heated in the fire, and thrown into urine, intended as a fomentation.

MYGDAOTH, in the *Jewish Antiquities*, a kind of mitre worn by the priests. See CIDARIS.

MYGDONIUM *marmor*, a name given by the ancients to a species of marble much used in their larger buildings. It was white variegated with black; but that black rather disposed in clouds and spots than veins. It is confounded with the *decimenum marmor*, by some writers; but that was always of a pure white, without the least variegation.

MYIAGRUS *Deus*, in the *Heathen Mythology*, a name given sometimes to Jupiter, and sometimes to Hercules, on occasion of their being sacrificed to for the driving away the vast numbers of flies which infested the sacrifices on certain public occasions. The word is usually spelt *Myagrus*; but this must be an error, as this word does not express the *fly-destroyer*, but the *mouse-destroyer*; and we have it sufficiently testified by the ancients, that flies were the only creatures against whom this deity was invoked. Pliny calls this deity also *Myiodes*, and tells us, that the flies which used to pester the Olympic rites went away in whole clouds, on the sacrificing a bull to this god. We find in Athenæus also, that this sacrificing to the god of flies, at the Olympic games, was a constant custom. Some distinguish these two deities, and tell us, that the latter, or MYIODES, used to visit the nations in vengeance, with a vast multitude of flies; and that, on paying him the due honours of a sacrifice, they all went away again; and this seems to agree with what Pliny tells us in some places.

At the time of the Olympic games, Jupiter was worshipped under the name of the *Apomyos*, or *Myiagrus Deus*, to supplicate the destruction of those troublesome creatures. This happened only once in many years, when the sacrifices were performed there; but the Elians worshipped him continually under this name, to deprecate the vengeance of heaven, which usually sent, as they expressed it, an army of flies, and other insects, toward the latter end of the summer, that infested the whole country with sickness and pestilence.

MYIODES *Deus*, in the *Heathen Mythology*, a name given sometimes to Hercules, but more frequently to Jupiter, to whom a bull was sacrificed, in order to make him propitious in driving away the flies that infested the Olympic games.

MYLASSENSE *marmor*, in the works of the ancients, a name used for a species of marble, dug near a city of that name in Caria. It was of a black colour, but with an admixture of purple; the purple not disposed in veins, but diffused through the whole mass: it was much used in building among the Romans.

MYLE, a word used by some authors as a name for the *pastilla* or *limpet*, and by others to express what we call a mole, or false conception in the uterus.

MYLOGLOSSI, in *Anatomy*, a pair of muscles, thus called because arising about the backside of the molares, or grinding-teeth, and inserted into the ligament of the tongue; helping to pull it upwards.

These are the same with what Mr. Cowper calls STYLOGLOSSI.

MYLOHYOIDEUS, in *Anatomy*, a broad, but short muscle, lying immediately under the biventer muscle of the jaw, and which, springing from the lower margin on each side the under jaw, is inserted into the basis of the OS HYOIDES.

It is made up of two equal fleshy portions, one lying on the right side, the other on the left, both on the same plane, and joined to a small middle tendon, which is inserted anteriorly in the middle of the basis of the os hyoides, and from thence runs directly forward, diminishing gradually in its course. This is therefore a true digastric muscle, and cannot be divided into two. Each portion is lined by fleshy fibres to the internal lateral part of the lower jaw, between the oblique prominent line and the basis under the first four *dentes molares* and the *coronus*; the anterior and greatest part of the other fibres of each portion run obliquely from before, backward to the middle tendon, in which they are regularly fixed, the anterior fibres being the shortest, and a small triangular void space being formed between them and the symphysis of the chin. The posterior fibres of each portion, which make about a fourth part of the whole, run likewise on each side of the os hyoides, and are inserted along the lower edge of its anterior or convex side, and from thence a little upward. Winslow's Anatomy, p. 254.

It has its name from the os hyoides, and the Greek μυλος, the *dentes molares*.

Besides the common use ascribed to this muscle, which is to move the hyoides, the tongue, and the larynx, both upwards, inwards, and sideways, its series of transverse fibres have a farther use when it is at rest; and that is, to compress the glands under the tongue, and by this means promote the discharge of saliva into the mouth from the lower salival ducts: whence it is we use this muscle when we want saliva in the mouth.

MYLON, in *Surgery*, is used for the largest tumors of the staphylomatous kind in the corner and uvea of the eyes. See STAPHYLOMA.

MYOCEPHALON, μυοκεφαλον, formed of μυια, *fly*, and κεφαλη, *head*, in *Medicine*, a little part of the tunica uvea, protended over the sight of the eye; occasioned by an ulceration of the part: so called, as resembling the head of a fly.

MYOCEPHALUS, a name given by some authors to the distemperature of the eyes, commonly known by the name of a STAPHYLOMA.

MYOCTONUM. See ACONITE.

MYODES *platysma*, a name given by some anatomical writers to what is called by others the quadratus genæ; it is a muscular expansion in the neck.

MYOLOGY, formed of μυς, μυος, *a muscle*, and λογος, *discourse*, in *Anatomy*, a description of the muscles; or the knowledge of what relates to the muscles of the human body. See *Tab. Anat. (Myol.)* See also MUSCLE.

MYOMANCY, a kind of divination, or method of foretelling future events by means of mice.

Some authors hold *myomancy* to be one of the most ancient kinds of divination; and think it is on this account that Isaiah, lxvi. 17. reckons mice among the abominable things of the idolaters. But, beside that it is not certain, that the Hebrew word עכבר used by the prophet, signifies a *mouse*, it is evident it is not the divination by that animal, be it what it will, is here spoken of; but the eating it.

MYOPARO, among the Romans, a kind of ship, which partly resembled a merchant-ship, and partly a ship of war, and was that which pirates mostly used.

MYOPIA, or MIOPIAS. See SHORT *sightedness*.

MYOPS, *myops*, a person who is short-sighted; or, as we popularly call it, *purblind*.

The word is Greek, μυωψ, compounded of μυς, *mouse*, and ωψ, *eye*; because, we suppose, the same conformation of the eye is observed in mice.

Myopes are properly such as see remote objects confusedly, and near ones distinctly. Those who labour under the opposite defect are called *presbytæ*.

The defect of *myopes* is not in the optic nerve, the pupil, or the like; but in the form of the cornea or crystalline, or the distance of the retina from the same. The crystalline or cornea being rounder or more convex than ordinary, the rays will be rendered more convergent than ordinary in passing through the same. See REFRACTION. By this means they will be brought to meet or concur at a less distance from the crystalline; so that if the retina be at its usual distance, they will concur before they reach it. It is the too great nearness, then, of the retina to the crystalline, that constitutes the *myopia*.

MYOPS, in *Natural History*, the *ear-fly*, an insect usually confounded with the breeze-fly, but really differing very much from it. This is common in woods and about path-ways, and never fixes on any other creatures except oxen. It has a long and somewhat flat body, and is of a blackish grey colour.

MYOSOTIS, in *Botany*. See MOUSE-*ear*.

MYOSURUS, in *Botany*. See MOUSE-*tail*.

MYOTOMY, *myotomia*, an anatomical dissection, or demonstration of the muscles. See MUSCLE.

MYRACOPON, a name used by some authors for an ointment intended to be used to the whole body to prevent lassitude. It is described by Galen.

MYRIAD, the number of ten thousand. Whence *myriarchus*, a captain or commander of ten thousand men.

MYRICA,

MYRICA, in *Botany*, See CANDLE-*berry tree*.

MYRINX, a word uſed by ſome to expreſs the membrane of the tympanum in the ear.

MYRIOPHYLLUM, in *Botany*, the name of a genus of plants of the *monoecia polyandria* claſs; called by others *pentaspermophyllum*. The characters are theſe: it produces both male and female flowers diſtinct on the ſame plant; in the male flower the perianthium is compoſed of four oblong and erect leaves, the exterior one being large, the interior one much ſmaller; there is no corolla; the ſtamina are eight capillary filaments, which are longer than the cup; theſe are of a looſe flaccid ſtructure; the antheræ are oblong; the female flowers always ſtand below the male; the perianthium is divided into a number of ſegments; the piſtil has four germina of an oblong figure; there are no ſtyles, but the ſtigmata are hoary; the ſeeds are placed four together, and are of an oblong figure. There are two ſpecies.

MYRMECIA, in *Medicine*, a kind of wart, by Latin writers called FORMICA.

MYRMECIAS *lapis*, the *wart-ſtone*, in *Natural Hiſtory*, a name given by ſome authors to a ſtone covered on the ſurface with wart-like excreſcences: it is a name of a very vague ſignification, ſome of the ſtones called by it being mere flints, and others owing their protuberances to coralloide bodies, the wires of aſteriæ, or other of the extraneous foſſils contained in them, and ſo lodged, that their ends juſt ſtand out.

MYRMECITES, in *Natural Hiſtory*, a name given by ſome authors to a ſmall ſtone, with ſome imaginary reſemblance of an ant in its ſhape. Others have alſo made it the name of ſuch pieces of amber as contain an ant, or the legs, wings, or other fragment or remains of that little animal.

MYRMECOPHAGA. See ANT-*eater*, and FOURMILIER.

MYRMELION, in *Natural Hiſtory*, a genus of the *neuroptera* INSECTS; the characters of which are, that the mouth is formed with jaws and furniſhed with two teeth; the palpi are four, and elongated; there are no ſtemmata; the tail of the male is a forceps, conſiſting of two ſtrait ſubulæ; the antennæ are elevated, and of the length of the thorax; and the wings deflexed. Linnæus enumerates five ſpecies.

MYRMIDONS, *Myrmidones*, in *Antiquity*, a people of Theſſaly, fabled to have ariſen from ants, or pilmires, upon a prayer put up for that purpoſe, by king Æacus, to Jupiter, after his kingdom had been diſpeopled by a ſevere peſtilence. In Homer and Virgil the *Myrmidons* are Achilles's ſoldiers.

MYRMILLO, among the Romans, a kind of Gallic armour uſed in theatrical ſhews: but ſome will have it to be the ſame that Achilles's *Myrmidones* wore; whence it had this name.

MYRMILLONES, a kind of gladiators in ancient Rome; called alſo *murmillones*, ſuppoſed by Lipſius to be an order that fought completely armed. See GLADIATOR.

Turnebus derives the name from the Myrmidons.

MYROBOLANS, *myrobalani*, a kind of medicinal fruit, brought from the Indies, much more uſed in the Arabic than the Greek pharmacy, and more among the ancients than the moderns, and ſtill more abroad than in England.

The word comes from the Greek μυρον, *medicament*, and βαλανος, *acorn*, as being ſomewhat in form of acorns, and uſed in medicine.

It is very evident from the writings of the ancient Greeks, that what we at this time call the *myrobalan* was not known to them under that name, and perhaps what they called ſo is not known to us at this time; our *myrobalans* being a ſort of plums, and their's being a dry fruit, rather of the nut-kind, and uſed in perfumed unguents, and other compoſitions of that kind, to give them a ſcent.—This variation from the original ſenſe of the word is not new, however; and the authors who began it are ſo far back, that it ſeems to have been an error of as old a date as any of this kind.

There are five kinds of *myrobalans*, or *purging Indian plums*: the firſt called *citrini*, of a yellowiſh red, hard, oblong, and the ſize of an olive. The ſecond called *black* or *Indian myrobalans*, of the bigneſs of an acorn, wrinkled, without ſtone. The third, *chebulic myrobalans*, the ſize of a date, of a yellowiſh brown, pointed at the end. The fourth *emblici*, round, rough, the ſize of a gall, of a dark brown. The laſt called *bellerici*, hard, yellow, round, the ſize of an ordinary prune, leſs angular than the reſt.

All the *myrobalans* have an unpleaſant, bitteriſh, auſtere taſte; and ſtrike an inky blackneſs with ſolution of chalybeate vitriol: they are ſaid to have a gently purgative, as well as an aſtringent and corroborating virtue; and are directed to be given in ſubſtance from half a dram to four drams, and in infuſion or ſlight decoction from four to twelve drams; but they have long been diſcarded from practice in this country.

MYROBATINDUM, in *Botany*, a name given by Vaillant to a genus of plants, which, with the *camara* of Plumier, and the *pſeudobalaurum* of Rivinus, is included by Linnæus under one general character, by the name LANTANA.

MYRRH, *myrrh*, from μυρω, of μυω, *I run or trickle*, a kind of gum reſin, iſſuing, by inciſion, and ſometimes ſpontaneouſly, from the trunk and larger branches of a tree growing in Arabia, Egypt, and eſpecially in Abyſſinia.

Authors are not agreed about the tree which produces this gum: it is true, they all make it ſmall and thorny; but they diſagree about the form of its leaves. In ſeveral reſpects it reſembles the *acacia vera*.

The inciſions are made twice a year, and the *myrrh*, oozing out, is received on ruſh-mats, diſpoſed underneath.

The druggiſts ſell two kinds of *myrrh*, viz. *myrrh in tears*, which they call *ſtacte*; the other *unguilata*, or in nails.

Of the firſt kind, the beſt is bright, yellow, and in tranſparent drops, friable, light, of a ſtrong diſagreeable ſmell: but this is very rare, and moſt of that in uſe is the *unguilated myrrh*, ſo called from little white ſpots obſerved thereon, much like thoſe on the nails of the fingers.

The beſt is in little maſſes, or tears, reddiſh and tranſparent; the fineſt pieces of *myrrh*, when broken, are ſometimes found to contain a kind of unctuous liquor, the moſt precious part of the *myrrh*, and the real *ſtacte* of the ancients.

But though Pliny and Dioſcorides ſpeak of *ſtacte* as if it was freſh or liquid *myrrh*, it is ſaid by a late traveller into Abyſſinia, that they could never ſee *myrrh* in that ſtate; becauſe it is ſaid by the natives to harden on the tree inſtantly as ſoon as it is expoſed to the air; and, therefore, the *ſtacte*, he ſuppoſes, muſt have been a compoſition of *myrrh* and ſome other ingredient. The quality of *myrrh* depends on the age and health of the tree, the manner of making the inciſion in it, the time of gathering the *myrrh*, and the circumſtances of the climate where it was gathered.

In order to have *myrrh* of the firſt or moſt perfect ſort, the ſavages chuſe a young vigorous tree, whoſe bark is without moſs, or any paraſite plant; and, above the firſt large branches, they give the tree a deep wound with an axe. The *myrrh*, which flows the firſt year, through this wound, is *myrrh* of the firſt growth, and never in very great quantity. This operation is performed ſome time after the rains have ceaſed, or from April to June; and the *myrrh* is produced in July and Auguſt. The ſap, once accuſtomed to iſſue through this gaſh, continues ſo to do ſpontaneouſly, at the return of every ſeaſon; but on account of the tropical rains, which lodge water and dirt in the gaſh, the tree has begun to rot, and become foul in the wounded part, and the *myrrh*, iſſuing in the ſecond year, is of a ſecond quality; and ſells at Cairo about a third cheaper than the firſt. The *myrrh*, alſo, produced from the gaſhes near the roots, and in the trunks of old trees, is of the ſecond growth and quality, and ſometimes worſe. This is, however, the good *myrrh* of the Italian ſhops, every where but in Venice: it is of a blackiſh red, foul colour, ſolid and heavy, loſing little of its weight by being long kept; and it is not eaſily diſtinguiſhed from that of Arabia Felix. The third and worſt kind is gathered from old wounds or gaſhes, formerly made in old trees; or *myrrh*, that, paſſing unnoticed, has hung upon the tree ungathered for a whole year; black and earth-like in colour, and heavy, with little ſmell and bitterneſs; and is apparently the *caucalis* of the ancients. Mr. Bruce farther obſerves, that the greaſineſs of *myrrh* is owing to the ſavages uſing goat-ſkins, anointed with butter, for ſtopping them, in which they put their *myrrh* when gathered; in which ſkins it remains, and is brought to market; ſo that this is a mark that *myrrh* is freſh gathered, which is the beſt quality that *myrrh* of the firſt ſort can have. Phil. Tranſ. vol. lxv. pt. 2. art. 40. p. 408.

Myrrh diſſolves almoſt totally in boiling water, but as the liquor cools, a portion of reſinous matter ſubſides. By evaporating the aqueous infuſion, an extract is obtained; and by diſtillation, with a boiling heat, the whole of its flavour ariſes, partly impregnating the diſtilled water, and partly collected and concentrated in the form of an eſſential oil; which is in ſmell extremely fragrant, in taſte remarkably mild, and ſo ponderous as to ſink in the aqueous fluid; whereas the oils of moſt, perhaps of all, of the other gummy reſins ſwim. If ſome powdered *myrrh* be incloſed in the white of a hard boiled

egg, and set in a moist cellar, the liquor, into which the egg will be gradually resolved, will extract nearly all the smell and taste of the *myrrh*. This liquor, which is commonly called *oil of myrrh, per deliquium*, may be precipitated and coagulated by spirit of wine: and this coagulum is soluble by water. Rectified spirit dissolves less of this concrete than water, but extracts more perfectly that part in which its bitterness, flavour, and virtues reside.

Tinctures of *myrrh*, made by digesting three ounces of the concrete in a quart of rectified or proof spirit, are kept in the shops, and given sometimes internally from fifteen drops to a tea-spoonful; but oftener used among us externally for cleansing ulcers, and promoting the exfoliation of carious bones. The extract, obtained by inspissating the tincture, is a fragrant, bitter, very tenaceous resin, amounting to one third or more of the weight of the *myrrh*.

This bitter, aromatic, gummy resin enters a great number of medicinal compositions: it is a warm corroborant, deobstruent, and antiseptic: it is given from a few grains to a scruple and upwards, in uterine obstructions, cachexies, putrid fevers, &c. and often employed also as an external antiseptic and vulnerary. Lewis.

Its bitterness renders it good for the stomach, and against worms; and it is chewed to prevent infection from contagious diseases. Dr. Quincy says, it is excellent to cleanse and strengthen the womb, and against tickling rheums; a good detergent; and, as such, much used externally in unguents for the healing of wounds: it makes the principal ingredient in embalming.

It is an apophthegm of chemists, derived from Van Helmont, that whoever can make *myrrh* soluble by the human body, has the secret of prolonging his days. And Boerhaave owns there seems to be truth in this from its resisting putrefaction. He himself, and other chemists before him, have given methods for making solutions of *myrrh*, but only by means of alcohol. It seems not a little surprising that such great chemists should never find out that *myrrh* is soluble in common water.

MYRRHIN, in *Antiquity*. See MURRINE.

MYRRHIS, in *Botany*. See CHERVIL.

MYRRHITES *lapis*, in *Natural History*, a name used by many of the ancient authors for a semi-pellucid stone of the nature of the agates; and seeming to have been the yellow cornelian of the moderns.

MYRSINE, in *Botany*. See *African* BOX-*tree*.

MYRTIDANON, a word used by the old Greek writers on medicine, but in a different sense by different authors. Hippocrates calls it a round fruit, which the Persians in his time called pepper, and which probably had all the heating qualities of that fruit. Dioscorides expresses it by an excrescence common on the trunk of the myrtle, and which, as he observes, is more astringent than the myrtle itself. *Myrtidanum vinum* also signified wine impregnated with myrtle.

MYRTIFORM *glands*. See GLAND.

MYRTIFORMES *carunculæ*, in *Anatomy*. See CARUNCULÆ, and *Tab. Anat. Splanchn. fig.* 9. *lit. f. f.*

MYRTIFORMIS *nasi*, in *Anatomy*, a name given by Santorini, and some others, to one of the muscles of the face, called by Albinus, *depressor alæ nasi*, and by Cowper and others, *depressor labii superioris, constrictor alæ nasi*.

MYRTILLUS, in *Botany*, a name by which some authors have called the black whortle berries: the *vitis idæa aculeata* of other authors.

MYRTITES, the name of a composition in the ancient pharmacy, made of fine honey, and the depurated juice of myrtle berries boiled up together to a consistence.

MYRTLE, *myrtus*, in *Botany*, a genus of the *icosandria monogynia* class. Its characters are these: the empalement of the flower is of one leaf cut into five points; the flower has five large oval petals, which are inserted in the empalement, and a great number of small stamina, which are also inserted in the empalement, terminated by small summits; the germen is situated under the flower, supporting a slender style, crowned by an obtuse stigma, and turns to an oval berry, with three cells crowned by the empalement, each cell containing two or three kidney-shaped seeds. Miller reckons nine, and Linnæus thirteen species.

There are several species of this plant preserved in our gardens; they are all easily propagated from cuttings. The best season for this is July; and the straitest and most vigorous young shoots are to be chosen. These should be cut off about six or eight inches long, and the leaves of the lower part stripped off to two inches high, and that part of the stalk twilled which is to be placed in the ground; they are to be planted in pots of light rich earth, at about two inches distance from each other, observing to close the earth very well about them, and give them a gentle watering: they are then to be removed under a common hot-bed frame, plunging them either into some old dung or tanners bark, and shaded and watered once in two or three days, till they have taken root: in about six weeks time, they will be rooted, and will begin to shoot, and must then be inured by degrees to the air; and in August, or the beginning of September, they should be removed into the open air, but placed in a warm situation, and sheltered from the winds; they should stand here till the middle of October, and then be removed into a green-house, where they should be placed so as to have as much air as possible. During the winter season, they must be frequently but gently watered, and if any decayed leaves appear, they should be constantly plucked off. In the spring following, they should be removed into separate pots of rich earth, preserving a ball of earth to the roots of each of them, watering them to settle the earth to their roots, and placing them under a frame, till they have taken root; and in May set out to the open air, in a warm and well defended place. They will require, in the summer, frequent waterings, and the dead leaves should be carefully picked off: they should be placed where they may have the benefit of the morning sun. As they advance in growth, they are to be shifted annually into pots of a larger size; and this should be done either in April or in August; and towards the end of October, they should always be removed into the green-house. Miller's Gard. Dict.

In Cornwall and Devonshire, where the winters are more favourable than in most other parts of England, there are large hedges of *myrtle*, which have been planted for several years, and are very thriving and vigorous; some of which are upward of six feet high.

MYRTLE, *candle-berry*. See CANDLE-*berry tree*.

The common *Dutch myrtle* grows wild in waste watery places, and abounds in the isle of Elv: the leaves, flowers, and seeds of this plant have a strong fragrant smell, and a bitter taste. They are said to be used among the common people for destroying moths, and cutaneous insects; internally, in infusions, as a stomachic and vermifuge; and as a substitute for hops, for preserving malt liquors, which they render more inebriating, and consequently less salubrious: which quality is said to be destroyed by boiling. Lewis.

MYRTLE-*berries*, *myrtilli*, the fruit of the *myrtle*, with which we are supplied from the southern parts of Europe. The fruit is at first green, but becomes black gradually: within it is a white seed, in form of a crescent, solid, hard, and of an astringent taste; while the fruit continues on the trees, it is succulent and smooth, and only becomes hard and wrinkled, because dried in the sun for the convenience of carriage.

Myrtle-berries are rough and astringent, and are chiefly recommended in alvine and uterine fluxes, and other disorders from relaxation and debility; and appear to be among the milder restringents and corroborants, in the way of syrup, as a strengthener against fluxes and abortion.

The perfumers likewise use them in their perfumes, and draw an essence from them. The German dyers make a blue colour from them. In some places the leaves and branches are also used in the tanning of leather.

A *myrtle* crown was worn by the general to whom an OVATION was decreed, the reason of which, according to Plutarch, in his life of Marcellus, was, that as an ovation was decreed for some remarkable success obtained by treaty, or without much bloodshed, it was proper that the general, at his public appearance, should be crowned with the tree sacred to Venus, who, of all the deities, was supposed to be most averse to the horrors of war.

MYRTLE *sumach*. See SUMACH.

MYRTOCHEILIDES, a name given by some authors to the nymphæ in the female pudenda.

MYRTUS, the *myrtle*, in *Botany*. See MYRTLE.

MYRTUS *sylvestris*, the *wild myrtle*, in *Botany*, a name given by some authors to *ruscus*, or BUTCHER'S *broom*, from some faint resemblance of its leaves to those of the *myrtle*.

MYRUS, in *Zoology*, a kind of sea-serpent, a fish of the eel class, supposed by some to be the male murœna, but erroneously. Its snout is very long and sharp-pointed; its body black, slender, and round, without scales, and free from spots; the cavity for the gills is only one on each side; near the neck there are some small yellow dots to be seen, while the creature is alive; but these are scarce visible after it is dead: its flesh is tender and delicate.

MYS, in *Ichthyology*, a name given by Ælian, Appian, and many others, to the fish called *asprisucus* by the later writers; the *asper* and *aburus* of others of the ancients. See GOAT-*fish*.

MYSIA, *μυσια*, in *Antiquity*, a feſtival in honour of Ceres. For the origin and ceremonies obſerved in it, ſee Potter, Archæol. Græc. lib. ii. cap. 20. tom. i. p. 415.

MYSTERY, *myſterium*, ſomething ſecret, or hidden; impoſſible or difficult to be comprehended.

The word comes from the Greek *μυστηριον*; and that, according to ſome etymologiſts, from *μυω, claudo, taceo, I ſhut, I am ſilent*, and *στομα, mouth*; but then whence comes the *τ*? Muſt the *υ* in *στομα* be converted into an *τ*? The word ſeems derived, with more propriety, from the Hebrew סתר *ſater, to hide*; whence is formed מסתר *miſtar, a hidden thing*.

Myſtery is primarily uſed in ſpeaking of certain truths revealed in Scripture, into the full underſtanding whereof human reaſon cannot penetrate. Such are ſaid to be the doctrines of the *Trinity*, the *Incarnation*, &c.

We have an epitome of the *myſteries of faith*, or the *myſteries of Chriſtianity*, in the ſymbols or creeds, compiled by the apoſtles, the council of Nice, and St. Athanaſius. See CREED.

In ſome of theſe, mention is made of the *myſtery* of the Trinity; the *myſteries* of the incarnation of the Son of God, his death and paſſion, and his deſcent into hell for the redemption of mankind; of his reſurrection the third day, his aſcenſion into heaven, his ſitting on the right hand of God, and his coming again to judge the world; of the divinity, and conequality of the Holy Ghoſt with the Father and the Son; of the unity of the church; of the communion of ſaints; the participation of the ſacraments; and the general reſurrection. Such are the principal *myſteries of faith*; which the church declares neceſſary to be known and believed, in order to ſalvation.

From the earlieſt ages there have been particular feſtivals inſtituted in honour of theſe *myſteries*; to return thanks to God for having revealed them, and to oblige the miniſters and paſtors to inſtruct the people therein.

Such are the feaſt of the *myſtery of the Incarnation*, called alſo *Chriſtmas*; thoſe of the *Circumciſion*, *Paſſion*, *Reſurrection*, &c. See INCARNATION, CIRCUMCISION, EASTER, and EPIPHANY.

The heathens alſo had their *myſteries*, particularly thoſe of Ceres (ſee ELEUSINIA), the *Bona Dea*, &c. The Egyptian prieſts concealed the *myſteries* of their religion and philoſophy under hieroglyphics. Thoſe who revealed the *myſteries* of the *Bona Dea* were ſeverely puniſhed; and none were truſted with them but thoſe ſolemnly initiated, and ſworn to ſecrecy.

But theſe were not called *myſteries*, as being incomprehenſible, or raiſed above the power of reaſon; but becauſe they were covered and diſguiſed under types and figures, to raiſe the greater veneration in the people.—The *myſteries* of paganiſm were uſually celebrated in caves and grottos, fitter to conceal crimes than to celebrate *myſteries* in.

Each of the pagan gods had, ſays biſhop Warburton, beſides the public and open, a ſecret worſhip paid them; into which none were admitted but thoſe who had been ſelected by preparatory ceremonies, called initiation. This ſecret worſhip was termed the *myſteries*. The firſt and original *myſteries*, of which we have any account, were thoſe of Iſis and Oſiris in Egypt; from whence they were derived to the Greeks, under the preſidency of various gods, as the inſtituter thought moſt for his purpoſe. He obſerves, that the nature and end of all theſe *myſteries* were the ſame, viz. to teach the doctrine of a future ſtate. And he repreſents the deſign of them in general to have been, to engage men to a holy and virtuous practice, to give them juſt notions of religion, and to detect the error of the vulgar polytheiſm. And he concludes his account of the *myſteries* with obſerving, that there were three things about which they were principally concerned: viz. 1. The riſe and eſtabliſhment of civil ſociety. 2. The doctrine of a future ſtate of rewards and puniſhments. 3. The error of polytheiſm, or the principle of the unity. Which latter was the object of the greater *myſteries*, in which the whole deluſion of paganiſm was diſcloſed, and the initiated were inſtructed, that Jupiter, Mercury, Venus, Mars, and the whole rabble of licentious deities, were only deified mortals: and that God alone was the Creator of the univerſe, who pervaded all things by his virtue, and governed all by his providence: whereas in the leſſer *myſteries*, which were preparatory to the other, the general belief of a providence, and future ſtate, and its conſequent engagements to a virtuous life were inculcated. But as theſe *myſteries*, according to the biſhop's hypotheſis, were an inſtitution of the ſtate for the benefit of the people, it is natural to inquire into the reaſons of their being kept ſecret: which, he ſays, were the following; nothing ſtimulates curioſity like that which retires from obſervation, and ſeems to forbid ſearch; and yet there was a neceſſity of teaching ſome things to the initiated, not expedient for others to know: hence he obſerves, that the ſecret in the leſſer *myſteries* was ſome hidden rites and ſhews, to be kept from the people, only to inrige their curioſity; and that the ſecret in the greater was ſome hidden doctrines to be kept from the people for the contrary purpoſe. Beſides, as the legiſlators had been principally concerned in the riſe of the vulgar polytheiſm, this circumſtance furniſhed another reaſon for the ſecrecy attending theſe *myſteries*. And that theſe *myſteries* were invented, eſtabliſhed, and ſupported by the legiſlature, he argues from the place of their origin, which was Egypt, where all religious worſhip was formed and propagated by ſtateſmen, and directed to political ends: becauſe the ſages who brought them out of Egypt, and propagated them in Aſia, Greece, and Britain, were all kings or legiſlators; becauſe the ſtate preſided in the *myſteries*; becauſe, according to their original inſtitution, neither ſlaves nor foreigners, who had no concern, no property, and no country, were to be admitted into them; becauſe an inſtitution, which taught the neceſſity of a ſtrict and holy life, muſt be the invention of legiſlators to whoſe ſcheme virtue and the proſpect of immortality were ſo neceſſary; and hence they were actually of infinite uſe to the ſtate: and finally from the expreſs teſtimony of Plutarch, who, in his Treatiſe of Iſis and Oſiris, aſcribes them to this original. However, theſe *myſteries* in proceſs of time, greatly degenerated; one cauſe of their corruption ſeems to have been the ſeaſon in which they were performed, and the profound ſecrecy obſerved in them; for the night gave opportunity to wicked men to attempt evil actions; and the ſecrecy, encouragement to perpetrate them. Another cauſe of their depravation was their being ſometimes under the patronage of thoſe deities, who were ſuppoſed to inſpire and preſide over irregular paſſions, ſuch as Bacchus, Venus, and Cupid; to which the biſhop adds, the hierophant's withdrawing himſelf from the care and inſpection of the civil magiſtrate.

Such is the ingenious and plauſible ſcheme largely diſcuſſed and maintained by Dr. Warburton, in his Divine Legation, &c. book ii. ſec. 4.

However, other learned writers have advanced a very different opinion on this ſubject. Dr. Leland, in particular, has very accurately examined the origin and ends of the inſtitution of *myſteries*. According to this writer they ſeem to have been originally deſigned to tame and civilize the rude and barbarous people, to form and poliſh their manners, and by ſhews and repreſentations, which were fitted to ſtrike the imagination, to bring them to a greater awe and veneration for the laws and religion of their country; which among the pagans was always regarded as a neceſſary ingredient in a virtuous character. On this account they are highly commended by Cicero, de Leg. lib. ii. cap. 14. as they tended to reclaim men from a rude and ſavage life; and they were called *initia*, becauſe they furniſhed the firſt principles of a human and civilized life. But whatever was the original intention of theſe *myſteries*, there is great reaſon to apprehend, that upon the whole they proved rather detrimental than advantageous to the cauſe of virtue; and the conception of them ſeems to have been owing to a fundamental defect in their original conſtitution.—Dr. Leland farther examines whether and how far the *myſteries* were deſigned to detect the error of polytheiſm, and to inſtruct the initiated in the knowledge of the one true God. With reſpect to this point he maintains, that the whole evidence, produced by the biſhop, amounts only to this; that in the *myſteries* the initiated were inſtructed that the popular deities had been once men; but no proof is brought, that the *αποφθεγματα* overthrew the vulgar polytheiſm, the worſhip of dead men; nay, the inſtitutors of the *myſteries*, whilſt they taught the initiated, that the gods, commonly received, had been once men, took care that the public religion ſhould not ſuffer by it, by letting them know, that, notwithſtanding this, they ought to be regarded as gods, and to have that divine worſhip and honour rendered to *them*, which ancient tradition and the laws required. The Chriſtians, indeed, argued from the hiſtory of the heathen gods to diſprove their divinity: and this was probably the reaſon why the myſtagogues were very careful in their entrance on the celebration of the *myſteries*, that no Chriſtian ſhould be preſent at them.

Dr. Leland farther contends, that the doctrine of the unity was not taught in the *myſteries*. With this view he examines the teſtimonies adduced by the biſhop, which, he ſays, afford no ſufficient evidence that they taught the doctrine of the unity. Beſides, there is great reaſon to think that the notion given of the Deity in the *myſteries* was not very right and juſt: and moreover, if they had taught juſt notions of God, theſe could be of no great uſe, becauſe they taught this part of the ſe-

tret doctrine of the *mysteries* to very few perſons. It is farther urged, that the legiſlators and civil magiſtrates, who firſt inſtituted the *myſteries*, and who regarded not truth but utility, could never in good earneſt attempt to draw the people off from that polytheiſm, which they themſelves had encouraged and eſtabliſhed for the welfare of the ſtate, and to keep the people under a greater veneration for the laws. And the *myſteries* ſeem to have been deſigned, not to diſcard the worſhip of the deities, to whom they were appropriated, but to add a greater ſolemnity to it. To which it may be added, from fact and experience, that, though the *myſteries* were generally celebrated in almoſt all the heathen nations, and eſpecially throughout the whole Roman empire, no effect of them appeareth to the contrary of the people from their polytheiſm or idolatry: nor is it conceivable, if the deſign of the *myſteries* were as laudable as Dr. Warburton repreſents, that the ancient Chriſtian writers ſhould have ſo univerſally exclaimed againſt them. See Leland's Advantage and Neceſſity of the Chriſtian Revelation, vol. ii. pt. 1. chap. 9.

MYSTERY, in *Scripture Language*, is uſed with ſome latitude. Sometimes it denotes any thing not to be known without divine revelation.

MYSTERY is alſo uſed to denote the ſecret things which God has diſcovered by his miniſters, the prophets, Jeſus Chriſt, and the apoſtles.

Mathematicians have been accuſed of introducing *myſteries* into geometry, which ought to have none. See the Analyſt; and Mr. Maclaurin's Fluxions, in the Introduction and other places. See alſo PARADOX.

MYSTERY, in *Engliſh Antiquity*, is a term formerly applied to our dramatic exhibitions. It is well known, ſays Mr. Percy, in his Reliques of Ancient Engliſh Poetry, that dramatic poetry in this and moſt other nations of Europe, owes its origin, or at leaſt its revival, to thoſe religious ſhews, which in the dark ages were uſually exhibited on the more ſolemn feſtivals. At thoſe times they were wont to repreſent in the churches, the lives and miracles of the ſaints, or ſome of the more important ſtories of ſcripture. And as the moſt myſterious ſubjects were frequently choſen, ſuch as the incarnation, paſſion, and reſurrection of Chriſt, &c. thoſe exhibitions acquired the name of *myſteries*. At firſt they were probably a kind of dumb ſhows, intermingled, perhaps, with a few ſhort ſpeeches: at length they grew into a regular ſeries of connected dialogues, formally divided into acts and ſcenes. Specimens of theſe, in their moſt improved ſtate, may be ſeen in Dodſley's Old Plays, and in Oſborne's Harleian Miſcellany. As the old *myſteries* frequently required the repreſentation of ſome allegorical perſonage, ſuch as Death, Sin, Charity, Faith, and the like, by degrees the rude poets of thoſe unlettered ages, towards the ſixteenth century began to form complete dramatic pieces, conſiſting entirely of ſuch perſonifications. Theſe they intitled moral plays, or moralities. The *myſteries* were very inartificial, repreſenting the ſcripture ſtories ſimply according to the letter. But the moralities are not devoid of invention; they exhibit outlines of the dramatic art; containing ſomething of a fable or plot, and even attempting to delineate characters and manners.

MYSTERY, *additions of*. See ADDITION.

MYSTES. See HYDROMYSTES.

MYSTICAL, *nutrisse*, MYSTIC, ſomething *myſterious*, or allegorical. See MYSTERY, ALLEGORY, &c.

The commentators on the Scripture, beſides a literal, find alſo a *myſtical*, and a moral meaning. The Bible, they contend, is a book written both within-ſide and without-ſide: within-ſide, in reſpect to the *myſtical*, internal, ſublime, and hidden ſenſe; and without-ſide, in reſpect to the literal and grammatical ſenſe, immediately expreſſed by the words.

In effect, ſeveral of the ancient fathers, and doctors of the church, underſtand the books mentioned in Ezek. ii. 10. and in the Apocalypſe, v. 1. *which were written both within-ſide, and without*, of the Scriptures; and take the literal and *myſtical* ſenſe to be here fairly intimated.

The ſenſe of Scripture, ſay they, is either that immediately ſignified by the words and expreſſions in the common uſe of language: or it is mediate, ſublime, typical, and *myſtical*; wherein the things themſelves ſignified are made to ſignify ſtill other and farther things, according to the particular deſign and intention of God, and of the prophets and apoſtles inſpired by him.

The literal ſenſe they again divide into *proper* literal, which is contained in the words taken ſimply and properly: and *metaphorical* literal, where the words are to be underſtood in a figurative and metaphorical ſenſe: as, *where the right eye is commanded to be plucked out*, &c.

Wherever the proper literal ſenſe contains any thing abſurd or indecent, there recourſe muſt be had to the metaphorical literal ſenſe.

All Scripture has a true literal ſenſe, but it has not always a *myſtical* one. We muſt ever underſtand it in the literal ſenſe, when it ſpeaks immediately of any of the laws of nature, of charity, of doing good; when it gives us inſtructions for the conduct of life, for regulating our manners; and when it relates any matter of fact, or point of hiſtory.

The ſame paſſage of Scripture has ſometimes ſeveral ſenſes, expreſſed and ſignified immediately by the words taken in their proper, and their figurative ſenſe, and which appear to have been all intended, by the inſpired perſon who ſpoke them, as having been ſo underſtood by others likewiſe inſpired. As thoſe words in Pſalm ii. *Thou art my Son, this day have I begotten thee*; which St. Paul underſtands, according to the ſtrict letter, in Heb. i. 5 of the generation of Jeſus Chriſt in time: and in Acts xiii. 33. he takes them in a metaphorical ſenſe, and applies them to our Saviour's reſurrection. Thus, in Hoſea xi. 1. the words of the prophecy, *I have called my Son out of Egypt*, are underſtood literally of the children of Iſrael, whom God brought out of Egypt, under the conduct of Moſes; and yet in Matt. ii. 15 they are underſtood metaphorically of Jeſus Chriſt.

The *myſtical ſenſe* of Scripture is that which the things expreſſed by the words do farther ſignify; or it is a ſecond ſignification held forth or ſignified by the firſt: this ſecond being expreſſed immediately by the firſt, and mediately by the words themſelves.

Writers allow of three kinds of *myſtical* ſenſes in the Word of God: the firſt correſponding to faith, and called *allegorical*; the ſecond to hope, called *anagogical*; and the third to charity, called the *tropological ſenſe*.

The four ſenſes, and their applications, are included in the Latin diſtich,

Litera geſta docet, quid credas allegoria,
Moralis quid agas, quo tendas anagogia.

Sometimes the ſame word in Scripture is to be taken in all the four ſenſes. Thus the word *Jeruſalem* literally ſignifies the capital of Judæa; allegorically, the church militant; tropologically and morally, a believer; and anagogically, heaven.

So, that paſſage in Geneſis, *Let there be lights, and there were lights*, ſignifies, according to the letter, corporeal light; by the allegory, the Meſſiah; in the tropological ſenſe, grace; and anagogically, beatitude, or the light of glory.

MYSTIC *theology* denotes a refined and ſublime kind of divinity, profeſſed by the *myſtics*.

It conſiſts in a knowledge of God, and divine things, not acquired in the common way, but infuſed immediately by God, and which has the power to move the ſoul in an eaſy, calm, devout, effective manner; to unite it ultimately to God; to illumine the underſtanding, and to warm and enliven the will, in an extraordinary manner.

Among the writings attributed to Dionyſius the Areopagite, is a diſcourſe of *myſtic theology*. Several others have written on the ſame ſubject, both ancients and moderns.

MYSTICS, *myſtici*, a kind of religious ſect, diſtinguiſhed by their profeſſing pure, ſublime, and perfect devotion, with an entire diſintereſted love of God, free from all ſelfiſh conſiderations.

The *myſtics*, to excuſe their fanatic ecſtaſies, and amorous extravagances, alledge that paſſage of St. Paul; *The Spirit prays in us by ſighs and groans that are unutterable*. Now, if the Spirit, ſay they, pray in us, we muſt reſign ourſelves to its motions, and be ſwayed and guided by its impulſe, by remaining in a ſtate of mere inaction.

Paſſive contemplation is that ſtate of perfection to which the *myſtics* all aſpire.

The authors of this *myſtic* ſcience, which ſprung up towards the cloſe of the third century, are not known; but the principles from which it was formed are manifeſt.—Its firſt promoters proceeded from the known doctrine of the Platonic ſchool, which was alſo adopted by Origen and his diſciples, that the divine nature was diffuſed through all human ſouls, or that the faculty of reaſon, from which proceeds the health and vigour of the mind, was an emanation from God into the human ſoul, and comprehended in it the principles and elements of all truth, human and divine. They denied that men could by labour or ſtudy excite this celeſtial flame in their breaſts, and, therefore, they diſapproved highly of the attempts of thoſe, who, by definitions, abſtract theorems and profound ſpeculations, endeavoured to form diſtinct notions of truth, and to diſcover its hidden nature. On the contrary, they maintained that ſilence, tranquillity, repoſe, and ſolitude, accompanied with ſuch acts as might tend to extenuate and exhauſt the body, were the means by which the hidden and internal word was excited to produce its latent virtues, and to inſtruct men in the knowledge of divine things. For thus they reaſoned:

those who behold with a noble contempt all human affairs, who turn away their eyes from terrestrial vanities, and shut all the avenues of the outward senses against the contagious influences of a material world, must necessarily return to God, when the spirit is thus disengaged from the impediments that prevented that happy union. And in this blessed frame, they not only enjoy inexpressible raptures from their communion with the Supreme Being, but also are invested with the inestimable privilege of contemplating truth undisguised and uncorrupted in its native purity, while others behold it in a vitiated and delusive form.

The number of the *mystics* increased in the fourth century, under the influence of the Grecian fanatic, who gave himself out for Dionysius the Areopagite, disciple of St. Paul, and probably lived about this period: and by pretending to higher degrees of perfection than other Christians, and practising greater austerity, their cause gained ground, especially in the Eastern provinces, in the fifth century. A copy of the pretended works of Dionysius was sent by Balbus to Lewis the Meek, in the year 824, which kindled the holy flame of mysticism in the Western provinces, and filled the Latins with the most enthusiastic admiration of this new religion.

In the twelfth century, these *mystics* took the lead in their method of expounding Scriptures; and, by searching for mysteries and hidden meaning, in the plainest expressions, forced the word of God into a conformity with their visionary doctrines, their enthusiastic feelings, and the system of discipline, which they had drawn from the excursions of their irregular fancies. In the thirteenth century, they were the most formidable antagonists of the schoolmen; and towards the close of the fourteenth, many of them resided and propagated their tenets almost in every part of Europe. They had, in the fifteenth century, many persons of distinguished merit in their numbers: and in the sixteenth century, previous to the Reformation, if any sparks of real piety subsisted under the despotic empire of superstition, they were only to be found among the *mystics*.

The principles of this sect were adopted by those called QUIETISTS in the seventeenth century: and, under different modifications, by the QUAKERS and METHODISTS.

MYSTOCEROS, in *Ichthyology*, a name given by Gesner and some others to that species of the silurus which we call the sheat-fish. It is the glanis of Pliny, and the rest of the old authors; the silurus of Rondeletius and others. It is distinguished by Artedi by the name of the silurus with four beards under the chin. It is plainly to be known from the fish called the *lake*, by this character, that having only one beard; it is a genuine species of SILURUS.

MYSTRUM, among the *Ancients*, a liquid measure, which was the fourth part of the cyathus.

It weighed about two drams and a half of oil; and of water or wine, two drams two scruples. It was much about our small spoonful.

MYSTUS *fluviatilis*, in *Ichthyology*, a name by which some writers, particularly Bellonius, have called the common *barbel*. See BARBUS.

MYSTUS *marinus*, the *sea-barbel*, the name of a fish caught in the Adriatic, and common in the markets of Venice. It is of an oblong figure, and in colour of a silvery white, variegated on each side with ten obliquely transverse black lines; its belly is very white; its tail is forked, and its head long; its back fin has part of its rays prickly, part soft to the touch; its eyes are not large, and their irises are yellow; its lips are prominent, thick, and soft, and only serrated in the place of teeth; but in the hinder part of its mouth it has several rows of short and large *molares* or grinders; its scales are large, and adhere firmly to the flesh. It is a very well tasted fish.

MYSTUS *Niloticus*, in *Ichthyology*, a name given by Bellonius to a fish of the barbel kind, caught in the Nile. Its body is thick and short, and its belly very broad; it grows to so large a size as to weigh twenty pounds. Probably this may be no other than the common barbel growing to a larger size, as we see many fish will in some places more than others.

MYTACISM, *Μυταχισμος*, in *Rhetoric*, the too frequent repetition of the letter M, thus *mammam ipsam amo, quasi meam animam*.

MYTHOLOGY, *μυθολογια*, signifying a discourse or description of fables, from *μυθος*, *fabula*, and *λογος*, *sermo*, *discourse*, the history of the fabulous gods and heroes of antiquity; with the explanation of the mysteries or allegories couched therein.

Lord Bacon thinks that a great deal of concealed instruction and allegory was originally intended in most parts of the ancient *mythology*; he observes, that some fables discover a great and evident similitude, relation, and connection with the thing they signify, as well in the structure of the fable as in the meaning of the names, whereby the persons or actors are characterised.

The same writer thinks it may pass for a farther indication of a concealed and secret meaning, that some of these fables are so absurd and idle in their narration, as to shew an allegory even afar off: but the argument of most weight upon this subject, he takes to be this, that many of these fables appear by no means to have been invented by the persons who relate them: he looks on them not as the product of the age, nor invention of the poets, but as sacred relics as he terms them, genre whispers, and the breath of better times, that from the tradition of more ancient nations, came at length into the flutes and trumpets of the Greeks. He concludes, that the knowledge of the early ages was either great or happy: great, if they by design made this use of trope and figure; or happy, if, whilst they had other views, they afforded matter and occasion to such noble contemplations. See THEOLOGY.

MYTILUS, in *Natural History*. See MUSCLE.

MYTIS, a name used by some writers to express the black juice found in the mouth of the sepia or cuttle-fish, with which it colours the water when in danger of being taken, and by this means often makes its escape. It is also used by Hippocrates as the name of a sea-fish different from the sepia.

MYTTOTON, a word used by the ancients to express a mixt sort of country food, made of garlic, onions, eggs, cheese, oil, and vinegar. It was much eaten by the labouring people among the ancients, and accounted a very wholesome dish.

MYURUS, *μυουρος*, in *Medicine*, denotes a pulse which is continually weakening by insensible degrees, so that the second beat is fainter than the first, the third than the second, &c. See PULSE.

The word is compounded of *μυς*, *mouse*, and *ουρα*, *tail*; the diminution of the pulse being supposed like that of the thickness of the tail of that animal, which grows less from the root to the tip.

MYULITES *lapis*, in *Natural History*, a name given by some authors to a fossile body, part of an ASTEROPODIUM, which they have thought in single joints somewhat resembled the ears of a mouse.

MYXA, or MYXARIA, in the *Materia Medica*, a name used by some authors for the SEBESTENS, a sort of plum of Ægypt and Asia.

MYXINE, in *Natural History*, a genus of the *intestina* class of worms; the characters are, that the body is round and carinated in the lower part; the mouth is cirrous; the jaws are pinnated, and furnished with many sharp teeth; and it has no eyes. There is only one species, called by Linnæus the glutinous *myxine*.

MYXOLYDIAN, in *Ancient Music*, the first species of the DIAPASON.

MYXON, in *Ichthyology*, the name of a fish of the mullet-kind, called by others BAUCHUS.

It much resembles the common MULLET; but its head is less pointed, and its body is covered beside the scales with a mucous matter: it has a remarkable irregularity in the manner of its swimming, and looks red about the lips and covering of the gills.

N.

N, A liquid conſonant, or ſemi-vowel, and the thirteenth letter of the Greek, Latin, Engliſh, &c. alphabets.

The *N* is a naſal conſonant: its ſound is that of a d, paſſed through the noſe: ſo that when the noſe is ſtopped by a cold, or the like, it is uſual to pronounce d for *n*. M. l'Abbe de Dangeau obſerves, that in the French the *n* is frequently a mere naſal vowel, without any thing of the ſound of a conſonant in it. He calls it the Sclavonic vowel. The Hebrews call their *N*, *Nun*, which ſignifies *child*, as being ſuppoſed the offspring of M; partly on account of the reſemblance of ſound, and partly on that of the figure. Thus from the m, by omitting the laſt column, is formed *n*: and thus from the capital *N*, by omitting the firſt column, is formed the Greek minuſcule ν. Hence, for Biennius, &c. the Latins frequently uſe Binus, &c. and the ſame people convert the Greek ν at the end of a word into an m; as, *omnino*, *pharmacum*, &c. See M.

N before p, b, and m, the Latins change into m, and frequently into l and r, as in ludo, illudo; in rigo, irrigo, &c. in which they agree with the Hebrews, who, in lieu of Nun, frequently double the following conſonant; and the Greeks do the ſame, as when for Manlius, they write Μαλλιος, &c.

The Greeks, alſo, before κ, γ, χ, ξ, changed the ν into γ: in which they were followed by the ancient Romans, who for Angulus wrote Aggulus; for anceps, aggeps, &c. The Latins retrench the *n* from Greek nouns ending in ων as Ἀρης, *Ares*; βρασων, *brason*. On the contrary, the Greeks add it to the Latin ones ending in *o*: as Κατων, Νερων, for *Cato*, *Nero*.

In Engliſh, *N* has an invariable ſound: as *no*, *name*, &c. After *m* it is ſometimes almoſt loſt, as *condemn*, &c.

N, among the *Ancients*, was a numeral letter, ſignifying 900; according to the verſe in Baronius,

N quoque nongentos numero deſignat habendos.

And when a line was ſtruck over it N, nine thouſand.

Among the ancient lawyers, *N. L.* ſtood for Non liquet, i. e. the cauſe is not clear enough to paſs ſentence upon.

N. P. was uſed among the Romans for notarius publicus; *N. C.* for Nero Ceſar, or Nero Claudius. *N. B.* is uſed for Nota bene. In marine language, *N* ſtands for North.

N. or N°, in *Commerce*, &c. is uſed as an abbreviation of numero, number. Thus alſo, in *Medicine*, caryophyllorum, N° vi. ſignifies ſix cloves. *N* on the French coins, denotes thoſe ſtruck at Montpelier.

NAAM, or NAM, NAMIUM, in *Law*, the taking or diſtraining another man's moveable goods.

This is either *lawful*, or *unlawful* and prohibited.

NAAM, *lawful*, is a reaſonable diſtreſs, proportionable to the value of the thing diſtrained for; and anciently called either *vif* or *mort*, as it was made of quick, or dead chattel.

Lawful *Naam* is ſo either by the common law; as when a man takes another's beaſts doing damage in his ground; or by a man's particular fact, as on account of ſome contract, &c.

NAAM, *unlawful*, *vetitum namium*. See NAMIUM.

NABATHÆA *ſiliqua*, in the *Materia Medica*, a name given by the interpreters of Avicenna, and other of the Arabian phyſicians, to the *jembut*, or *aſſembut*, of thoſe authors.

It appears, from the accounts they have given us of this drug, that it was a long and ſlender pod, produced on a thorny tree. It has been generally ſuppoſed to be the ſame with the *carob*, or *ſiliqua dulcis*, but very erroneouſly. The ſame authors who mention this *aſſembut*, or *nabathæa ſiliqua*, mention that alſo under the name of the *almohati*, or *Syrian ſiliqua*, as it is by interpreted.

The *Syrian ſiliqua*, they ſay, purges, and is good in coſtiveneſs. The *nabathæan* they recommend to us, as an aſtringent in hæmorrhages. It is plainly to be inferred from this, that the *nabathæa ſiliqua* is different, in the greateſt degree from the Syrian pod, or *carob* fruit; and by its virtues, and the deſcription they give us of the thorny tree which produces it, it ſeems very probable that it was the pod of ſome ſpecies of the *acacia*.

NABCA, in *Botany*, a name by which ſome authors have called the tree more uſually deſcribed under the name of *amomum*, or the great jujube tree.

NABECH, in *Botany*, the name given by the Arabian writers to the fruit of the tree SADAR, which is the *lotus* of Dioſcorides, and the *acanthus* of Virgil. The fruit of this, which is round, and like a cherry, only ſmaller, was firſt called by this name *nabech*, or *nabuc*, but afterwards the tree was alſo called by it.

NABLUM, in Hebrew, *nebel*, an inſtrument of muſic among the Hebrews. The Seventy, and the Vulgate, tranſlate it ſometimes by *nablum*, and at other times by *pſalterium*, or *lyra*, or even *cithara*.

The *nablum* was a ſtringed inſtrument, very near of the form of a Δ, which was played upon by both hands, and with a kind of bow. See Calmet's Diſſertation concerning the Inſtruments of Muſic of the ancient Hebrews, prefixed to the ſecond volume of his commentary upon the Pſalms.

Kircher ſuppoſes that it was the ſame with the PSALTERY. See *Tab. Muſic. fig.* 7.

NABO, or NEBO, in *Mythology*, a deity of the Babylonians, who poſſeſſed the next rank to Bel. It is mentioned by Iſaiah, ch. xlviii. Voſſius apprehends that Nabo was the moon, and Bel the ſun; but Grotius ſuppoſes that Nabo was ſome celebrated prophet of the country, which opinion is confirmed by the etymology of the name, ſignifying, according to Jerom, one that preſides over prophecy.

NABOB, the name of a viceroy or governor of one of the provinces of the Mogul's empire in India.

NABONASSAR. The æra of NABONASSAR is famous: we know but little of the hiſtory of that prince; only that he was king of Babylon, and was alſo called Beleſus; though ſome will have him the Baladan mentioned in Iſaiah xxxix. 1. and 2 Kings xx. 12. Some even conjecture that he was a Mede; and that he was ſet on the throne by the Babylonians, upon their ſhaking off the government of the Medes.

The beginning of this prince's reign is of great importance in chronology; becauſe Ptolemy aſſures us, there were aſtronomical obſervations made by the Chaldæans from *Nabonaſſar* to his time; and Ptolemy, and the other aſtronomers, account their years from that epocha. See ASTRONOMY.

From the obſervations quoted by Ptolemy, it follows, that the firſt year of this æra is the 747th year before Jeſus Chriſt; and the 3967th of the Julian period. See EPOCHA.

The years of this epocha are Egyptian years, of three hundred and ſixty-five days each; commencing on the 29th of February, and reckoned, according to the computation of aſtronomers, from noon.

NABOTH, *ark of*, in *Anatomy*, a kind of ovary near the neck of the womb, diſcovered by *Naboth*, profeſſor of medicine in the univerſity of Leipſick.

NACRE, in *Natural Hiſtory*. See PINNA.

NADAB, the ſovereign pontiff, or high prieſt of the Perſians, whoſe dignity is the ſame as that of the muſti among the Turks; with this difference only, that the *nadab* may diveſt himſelf of his eccleſiaſtical office, and paſs to civil employment, which the muſti is not allowed to do. See MUFTI.

The *mofaib* takes place next after the mufti dulet, or prime minifter; he has two judges under him, called the feeik and the cafi, who decide all religious matters, grant divorces, and are preſent at contracts and public acts, and theſe have deputies in all the cities of the kingdom.

NADIR, in *Aſtronomy*, a point in the heavens diametrically oppoſite to the ZENITH.

The word is pure Arabic, where it ſignifies the ſame.

The *nadir* is that point directly under our feet; or a point in a right line drawn from our feet through the centre of the earth, and terminating in the under-hemiſphere.

The zenith and *nadir* are the two poles of the horizon, each being 90° diſtant from it, conſequently each in the meridian.

NADIR, *ſun's*, is the axis of the cone projected by the ſhadow of the earth; thus called, becauſe that axis being prolonged, gives a point in the ecliptic diametrically oppoſite to the ſun.

NADIR-*ibrihſun*, in the *Turkiſh Offices*, the ſuperintendant over the wardrobe.

NÆNIA, in *Mythology*, a goddeſs who preſided over lamentations and funerals; and who had a temple near Rome.

Nænia is alſo uſed for a funeral dirge or ſong, ſung on funeral occaſions.

NÆVUS, or NEVUS, in the *Animal Oeconomy*, denotes an excreſcence of fleſh in various parts of the bodies of children, ſuppoſed to have been occaſioned by frights, diſappointments, &c. of the mother, while the infant was in the womb. Theſe tumors ariſe in all parts of the body; they are of all figures and of all ſizes, and are ſometimes of the common colour of the ſkin, ſometimes black, red, &c. Many of them, both in ſhape and colour, reſemble fruits of ſeveral kinds, as mulberries, ſtrawberries, and the like; or animals, as mice, or ſpiders. They are to be removed, as warts, by ligature, cautery, or extirpation with the knife. But if they have large veſſels near their roots, if they are ſtrongly fixed to the bone, or if they ſeem to have a cancerous diſpoſition, it is much beſt for the ſurgeon to let them wholly alone; and where they are ſeated in the neighbourhood of arteries or large veins, if preſſed to extirpate them, he ſhould never be without cauteries, ſtyptics, bandages, and other neceſſary apparatus, in caſe of hæmorrhages. Heiſter's Surgery, p. 323.

See theſe accounted for under MONSTER. See alſo FOETUS, and IMAGINATION.

NAG. See HOBBY.

NAGEMULUS, in *Ichthyology*, a name given by ſome of the German authors to the fiſh called by Willughby and others, the *lucioperca*, or *pike-pearch*. It is truly a ſpecies of PEARCH, and is diſtinguiſhed from the common pearch, principally by having two long teeth on each ſide of the mouth.

NAHUM, or, *the Prophecy of* NAHUM, a canonical book of the Old Teſtament. *Nahum*, the ſeventh of the twelve leſſer prophets, was a native of Elkoſhai, a little village of Galilee. The ſubject of his prophecy is the deſtruction of Nineveh, which he deſcribes in the moſt lively and pathetic manner: his ſtyle is bold and figurative, and can hardly be exceeded by the moſt perfect maſters of oratory. This prophecy was verified at the ſiege of that city, by Aſtyages, in the year of the world 4378, ſix hundred and twenty-two years before Chriſt.

The time of *Nahum*'s death is unknown; the Greek menologies, and the Latin martyrologies place his feſtival on the firſt day of December.

NAIA, in *Zoology*, the name of 2 ſpecies of COLUBER, the ſcuta of whoſe abdomen are one hundred and ninety in number, and the ſquamæ of the tail ſixty.

NAIAS, in *Botany*, the name given by Linnæus to a genus of plants of the *dioecia monandria* claſs; called by Vaillant and Micheli *hydatis*. The characters are theſe: it produces male and female flowers diſtinct; in the male flowers, the perianthium is compoſed of one leaf of a cylindric figure, and truncated at the baſe, growing ſmaller at the top, and having at the mouth two oppoſite ſegments which bend backwards; the flower is compoſed of only one petal and is a tube of the length of the cup; its verge is divided into four ſegments, which are rolled backwards; there are no ſtamina, but the middle of the flower produces one oblong erect anthera; in the female flower there is no cup, nor any petal, but a piſtil whoſe germen is of an oval figure, and terminates in a bender ſtyle; the ſtigmata are ſimple; the fruit is an oval capſule, containing one oblong oval ſeed. There is only one ſpecies.

NAIADS, or NAIDS, NAIADES, derived from ναω, *I flow*, or from ναω, *I inhabit*, in *Mythology*, a ſort of nymphs, or heathen diviniti[illegible], ſuppoſed to preſide over fountains and rivers.

Strabo ſays, the *Naiads* were prieſteſſes of Bacchus.

What we learn of them in general is, that they were ſuppoſed to live in the palaces of the preſiding deities of fountains, lakes, and rivers. We have the names of no leſs than ſixteen of theſe deities, given us by Virgil, Georg. iv. ver. 336 to 340; and 343 to 345; in his account of Cirene's apartment only, in the watery palace of Peneus: and Ovid, lib. iii. el. 6. ver. 64. ſpeaks of a hundred, at leaſt, in the river Anio. They had often a name from the particular river they inhabited. They are deſcribed with long, bright hair, flowing down their ſhoulders; their faces ſhould have a ſhining, humid look, not unlike the Venus Anadyomene, of Apelles: their ſhape ſhould be fine, and their limbs well turned. Their robes, when they wear any, for they are moſt commonly quite naked, ſhould be of a greenith caſt; varied at pleaſure, ſome into lighter, and ſome into darker ſhades; and ſo thin, that you might diſcover all the turn of their limbs, and the fineneſs of their ſkin through them. They have ſometimes little flying veils, in gems of the ancients, over their heads; like thoſe goddeſſes of the air, which the Romans called Auræ, and which we call Sylphs. It was the uſual employment of the *Naiads* to attend at feaſts and they ſeem to have been little better than ſo many domeſtics to the preſiding water-deities. Spence.

NAIANT, or NATANT, q. d. ſwimming; a term in *Heraldry*, uſed in the blazoning of fiſhes, when drawn in a horizontal poſture; feſs-wiſe, or tranſverſely, acroſs the eſcutcheon; that being their natural ſwimming poſture.

NAILING *of cannon*, the driving of a nail, or iron ſpike, by force into the touch-hole of a piece of artillery; ſo as to render it for ſome time uſeleſs to the enemy.

NAILS, in *Anatomy*, a kind of horny excreſcences, growing over the ends of the fingers and toes of men, and ſeveral other animals; much of the ſame nature with the hoofs of others.

Hoofs are nothing elſe but a number of ſmall huſks, anſwering to ſo many papillæ of the ſkin; and it may be concluded, that *nails* are no more than the covers or ſheaths of the papillæ pyramidales of the ſkin, on the extremities of the fingers and toes, which dry, harden, and lie upon one another.

Their uſe is to ſtrengthen and defend the ends of the fingers in handling any hard and rugged bodies; that part being exceedingly ſenſible, by reaſon of the great number of nerves which terminate here for the ſenſation of feeling.

The *nails* are formed, and grow, after the ſame manner as the reſt of the body; their nouriſhment they receive from their roots, as is eaſily obſervable from the white ſpecks ſometimes ſeen on them, and which conſtantly recede from the root.

Dr. Pozzi endeavours to prove, that the *nails* grow out of the tendons, which are ſpread upon the laſt phalanx of the fingers and toes.

The Romans were very curious in the cutting and forming the *nails*, and had it done by artiſts, who made an employment of it.

The Chineſe doctors and literati pique themſelves on the exceſſive length of their *nails*. F. le Compte ſays, ſome of them wear *nails* near as long as their fingers.

NAILS, in *Building*, &c. are little metalline members, ſerving to bind or faſten the parts together, &c.

The ſeveral kinds of *nails* are very numerous. As *hack nails*; made with flat ſhanks to hold faſt, and not open the wood. *Clamp nails*, thoſe proper to faſten the clamps in buildings, &c. *Claſp nails*, whoſe heads are flatted, and claſping and ſticking into the wood, render the work ſmooth, ſo as to admit a plane over it: the moſt common in building are diſtinguiſhed by *10d. 20d. 2s.* &c. *Clench nails*, thoſe uſed by boat, barge, &c. builders, with boves or nuts, and often without: for fine work, they are made with claſp heads, or with the head beat flat on two ſides. *Clout nails*, thoſe ordinarily uſed for nailing on of clouts to axle-trees; they are flat headed *nails*, and iron work is uſually fixed with theſe *nails*. *Deck nails*, thoſe proper for faſtening of decks in ſhips, doubling of ſhipping, and floors laid with planks. *Dog nails*, or *jobent nails*, proper for faſtening of hinges to doors, &c. *Flat points* are of two kinds, viz. *long*, much uſed in ſhipping, and proper where there is occaſion to draw and hold faſt, yet no neceſſity of clenching; and *ſhort*, which are fortified with points, to drive into oak or other hard wood. *Lead nails*, uſed to nail lead, leather, and canvas, to hard wood: theſe are *clout nails* dipped in lead or ſolder. *Port nails*, commonly uſed to nail hinges to the ports of ſhips. *Ribbing nails*, uſed to faſten the ribbing, to keep the ribs of ſhips in their place in building. *Roſe nails* are drawn four-ſquare in the ſhank, and commonly in a round tool. *Rother nails*, chiefly uſed to faſten rother-irons to ſhips. *Scupper nails*, much uſed to faſten leather and canvas to wood. *Sharp nails*, much uſed, eſpecially in the Weſt-Indies, made with

with sharp points and flat shanks. *Sheathing nails*, used to fasten sheathing-boards to ships: the rule for their length is, to have them full three times as long as the board is thick. *Square nails*, of the same shape as *sharp nails*; chiefly used for hard woods. BRADS, long and slender, without heads, chiefly used for thin deal work, to prevent splitting. To which may be added *tacks*; the smallest serving to fasten paper to wood; middling, for wool-cards and oars; and larger, for upholsterers and pumps. They are distinguished by the names of white *tacks*, 2*d* 3*d*. and 4*d*. *tacks*.

Nails are said to be toughened, when too brittle, by heating them in a fire-shovel, and putting some tallow or grease among them.

Nails are sold six score to the hundred.

NAIL, in the *Manege*. The different position of the *nails* of the bridle, or left hand of the horseman, gives the horse a facility of changing hands, and forming his departure, and stop; by reason that the motion of the bridle follows such a position of the *nails*. To give a horse head, you must turn the *nails* downwards. To turn the horse to the right, you must turn them upwards, moving your hand to the right. To change to the left you must turn the *nails* down, and bear to the left. To stop the horse you must turn them upwards, and lift up, or raise your hand.

NAIL is also a sort of long measure, chiefly used in the commerce of cloths; containing the sixteenth part of a yard.

NAIRANGIA, formed from the Arabic *nairun*, the plural of *nur*, *light*, a kind of divination, in use among the Arabs, drawn from the several phenomena of the sun and moon.

NAIRES, NAHERS, or NAYERS, in *Modern History*, a name which is given by the Malabarians to the military of their country, who form a very numerous class or tribe, out of which the sovereigns of Malabar chuse their body-guard.

NAISSANT, in *Heraldry*, is applied to a lion, or other animal, shewing only the head, shoulders, fore-feet, and legs, with the tip of the tail; the rest of the body lying hid under the shield, or some charge, or ordinary thereon; from which it appears to be issuing or arising. See *Tab. Heraldry, fig.* 28.

Naissant differs from ISSUANT, as the animal in the former case issues out at the middle, and in the latter at the bottom of the shield or charge.

F. Menestrier says, *naissant* is only used for animals, which shew the bare head as arising out of the extremity of the chief, or from above the fesse.

NAKED, in *Architecture*. NAKED of a wall, &c. is the surface, or plane, from whence the projectures arise; or which serves as a ground to the projectures. See *Tab. Architect. fig.* 24.

Thus, we say, a pilaster ought to exceed the *naked* of the wall by so many inches; and that the foliages of a capital ought to answer to the *naked* of the COLUMN.

A flooring is said to be *naked*, before the boards are laid over the joists: the *naked* roofing or carcasing is applied to the roof before the tiles are laid on the rafters.

NAKED *fire*, is a term used by chemists for an open fire; or one where the containing vessel is immediately exposed to the FIRE.

NAKED *seeds*, in *Botany*, are such seeds of plants as are not inclosed in any pod, or case.

NAKED *stalk*, or *leaf*, among *Botanists*. See STALK and LEAF.

NAKIB, in the *Oriental Dignities*, the name of an officer who is a deputy to the cadilisker, or, as he may be called, the lord high chancellor of Egypt, appointed by the grand signior. His office is to carry the standard of Mahomet.

NAKIR, a word used by some medical writers to express a violent flatulence which passes from one limb to another, and is always attended with pain.

NAKOUS, an Egyptian musical instrument, made like two plates of brass, and of all sizes, from two inches to a foot in diameter; they hold them by strings fastened to their middles, and strike them together so as to beat time. They are used in the Coptic churches, and in the Mahometan processions.

NAL *la appella*, in *Botany*, a name used in the Horius Malabaricus to express an Indian shrub, or tree, from the roots of which they obtain an oil of a gold-yellow colour, and very agreeable smell, called *appel* oil. It is of a bitterish and sharp taste, and is in great esteem among them in pains of the head.

NAM. See NAAM.

NAMA, in *Botany*, a genus of the *pentandria digynia* class: the characters of which are, that the calyx is composed of five leaves; the corolla is divided into five segments; and the fruit is a single-celled capsule, with two valves. There are two species.

NAMAMTIA, in *Ichthyology*, a name given by the French to the *manati*, or SEA *cow*.

NAMATION, NAMATIO, in *Law*, the act of distraining or taking a DISTRESS. See NAAM.

In Scotland the word is particularly used for impounding. See POUND.

NAME, denotes a word whereby men have agreed to express some idea; or which serves to denote or signify a thing or subject spoken of.

This the grammarians usually call a NOUN, *nomen*, though their *noun* is not of quite so much extent as our *name*.

Seneca, lib. ii. de Beneficiis, observes, that there are a great number of things which have no *name*; and which, therefore, we are forced to call by other borrowed *names*. *Ingens est*, says he, *rerum copia sine nomine, quas cum propriis appellationibus signare non possumus, alienis accommodatis utimur*: which may shew why, in the course of this Dictionary, we frequently give divers senses to the same word.

It was Adam that first gave things their *names*, Genesis, ii. 19.

Names are distinguished into *proper* and *appellatives*.

NAMES, *proper*, are those which represent some individual thing or person; so as to distinguish it from all other things of the same species. As Socrates, which represents a certain philosopher.

NAMES, *appellatives*, or *general*, are those which signify common ideas; or which are common to several individuals of the same species,—as, horse, animal, man, oak, &c.

Proper names are either called *Christian*, as being given by us at baptism; or *surnames*: the first, imposed for distinction of persons; answering to the Roman prenomen.

The second, for the distinction of families, answering to the nomen of the Romans, and the patronymicum of the Greeks.

Originally, every person had but one *name*; as among the Jews, Adam, &c. among the Egyptians, Busiris; among the Chaldees, Ninus; the Medes, Astyages; the Greeks, Dionysius; the Romans, Romulus; the Gauls, Divitiacus; the Germans, Ariovistus; the Britons, Cassibelan; the English, Hengist, &c. and thus of other nations, except the savages of mount Atlas, whom Pliny and Marcellinus represent as anonymi, *nominis*.

The Jews gave the *name* at the circumcision, viz. eight days after the birth: the Romans to females the same day, and to males on the ninth; at which time they held a feast, called *nomenclatio*.

Since Christianity has obtained, most nations have followed the Jews, baptizing, and giving the *name*, on the eighth day after the birth, though this is far from being an uniform practice; our English ancestors generally baptized, and gave the *name*, on the birth-day.

The first imposition of *names* was founded on different views, among different people; the most usual was to mark the good wishes of the parents, or to intitle the children to the good fortune a happy *name* seemed to promise. Hence, Victor, Castor, Faustus, Statorius, Probus, &c.

Accordingly, we find such *names*, by Cicero called *bona nomina*, and by Tacitus, *fausta nomina*, were first first inrolled, and ranged in the Roman musters; first called to serve at the first sacrifices in the foundation of colonies, &c. And on the contrary, Livy calls Atrius Umber, *abominandi ominis nomen*: and Plautus, on occasion of a person named Lyco, i. e. Greedy wolf, says;

Visast nunc facite conjecturam, caterum
Quid id sit hominis, cui Lyco nomen sit.

Hence, Plato recommends it to men to be careful in giving happy *names*; and the Pythagoreans taught expressly, that the minds, actions, and successes of men, were according to their *names*, genius, and fate. Thus, Panormitan, *Ex bono nomine oritur bona præsumptio*; and thus the common proverb, *Bonum nomen bonum omen*: and hence the foundation of the Onomomantia.

Hence Camden takes it for granted, that the *names*, in all nations and languages, are significative, and not simple sounds, for mere distinction sake. This holds not only among the Jews, Greeks, Latins, &c. but even the Turks; among whom Abdalla signifies God's servant; Soliman, peaceable; Mahomet, glorified, &c. And the savages of Hispaniola, and throughout America, who, in their languages, *name* their children, Glittering Light, Sun-bright, Fine Gold, &c. And they of Congo, by the *names* of precious stones, flowers, &c.

To suppose *names* given without any meaning, however by the alteration of languages their signification may be lost, that learned author thinks, is to reproach our ancestors; and that contrary to the sense of all ancient writers. Porphyry notes, that the barbarous names, as

he

he calls them, were very emphatical, and very concise: and accordingly, it was esteemed a duty to be *agnomina*, or *sui nominis conditores*, as Severus, Probus, and Aurelius are called *sui nominis imperatores*.

And it was the usual way of giving *names*, to wish the children might discharge their *names*. Thus when Gunthram, king of France, named Clotharius at the font, he said *Crescat puer & hujus sit nominis executor*.

The ancient Britons, Camden adds, generally took their *names* from colours; because they painted themselves; but these names are now loft, or remain hid among the Welsh. When they were subdued by the Romans, they took Roman *names*; some of which ftill remain, corrupted; though the greateft part are become extinct, upon the admiffion of the Engliſh Saxons, who introduced the German *names*, as Cridda, Penda, Oſwald, Edward, &c. The Danes, too, brought with them their *names*; as Swayne, Harold, Knute, &c.

The Normans, at the Conqueſt, brought in other German *names*, as originally ufing the German tongue; ſuch as Robert, William, Richard, Henry, Hugh, &c. after the ſame manner as the Greek *names*, Afpafius, Boethius, Symmachus, &c. were introduced into Italy, upon the diviſion of the empire. After the Conqueſt, our nation, which had been averſe to foreign *names*, as deeming them unlucky, began to take Hebrew *names*, as Matthew, David, Samſon, &c.

The various *names* anciently, or at preſent, obtaining among us, from what language or people ſoever borrowed, are explained by Camden in his Remains.

Of late years it has obtained among us to give *ſurnames for Chriſtian names*; which ſome diſlike, on account of the confuſion it may introduce. Camden relates it as an opinion, that the practice firſt began in the time of Edward VI. by ſuch as would be godfathers, when they were more than half-fathers. Upon which, ſome were perſuaded to change their *names* at confirmation; which, it ſeems, is uſual in other countries. Thus, two ſons of Henry II. of France, chriſtened Alexander and Hercules, changed them at confirmation into Henry and Francis.

In monaſteries, the religious aſſume new *names* at their admittance; to ſhew they are about to lead a new life, and have renounced the world, their family, and even their *names*: v. g. Siſter Mary of the Incarnation, Brother Henry of the Holy Sacrament, &c.

The popes alſo change their *name* at their exaltation to the pontificate; a cuſtom firſt introduced by pope Sergius, whoſe *name*, till then, as Platina informs us, was Swinefnout. But Baronius refers it to pope Sergius I. and Onuphrius to John XII. or XIII. and at the ſame time adds a different reaſon for it from that of Platina, viz. that it was done in imitation of St. Peter and St. Paul, who were firſt called Simon and Saul. Indeed pope Marcellus, of late, refuſed to change his *name*.

In Italy, it is frequent to join the *name* of ſome ſaint, in a kind of devotion to the Chriſtian *name*; as Joannes Baptiſta Spinola, &c.

Among the ancients, thoſe deified by the heathen conſecrations had new *names* given them; as Romulus was called Quirinus, Melicertes, Portunus, or Portumnus, &c. New *names* were alſo given in adoptions, and ſometimes by teſtament: thus L. Æmilius, adopted by Scipio, took the *name* of Scipio Africanus; and thus Auguſtus, who at firſt was called C. Octavius Thurinus, being adopted by the teſtament of Julius Cæſar into his *name* and family, took the *name* of Caius Julius Cæſar Octavianus. *Names* were alſo changed at enfranchiſements into new cities. Thus Lucumo, at his firſt being made free of Rome, took the *name* Lucius Tarquinius Priſcus, &c. and ſlaves, when made free, uſually aſſumed their maſters *names*.

Thoſe called to the equeſtrian order, if they had baſe *names*, were always new-named, *nomina ingenuorum accipiunt Romanorum*. And among the primitive Chriſtians, it was the practice to change the *names* of the catechumens: thus the renegado Lucianus, till his baptiſm, was called Lucius.

NAME, *generical*. See GENERICAL.

NAME, *ſpecific*. See SPECIFIC.

NAME, *of the*, is a phraſe, frequent among *Hiſtorians* and *Genealogiſts*, to denote perſons of the ſame quality, and *name*. It is near nine hundred years ſince the emperors of the Weſt firſt began to diſtinguiſh themſelves in this manner by their number: and in the Italia Sacra of Ughellus, we meet with a charter of the emperor Louis le Debonnaire, ann. 818, wherein that prince ſtyles himſelf the firſt *of the name*. Le Blanc mentions a charter of the year 1084, wherein the emperor Henry III. ſtyles himſelf King of Italy, the fourth *of the name*, and emperor the third *of the name*.

Some French writers obſerve, that in a manuſcript preſerved in the king's library, their Lewis XI. is only ſtyled the ninth *of the name*; Louis the Debonnaire, and Louis the Stammerer, not being then reckoned in the number, becauſe they were emperors, as well as kings of France: on which footing, the preſent king, inſtead of the ſixteenth, ſhould only be the fourteenth *of the name*.

NAMIUM, NAAM, in *Law*. See NAAM.

NAMIUM *vetitum*, or *prohibitum* NAAM, is an unjuſt taking the cattle of another, or driving them to an unlawful place, pretending damages done by them.

Such, e.g. is that when the bailiff of a lord diſtrains beaſts or goods, and the lord forbids his bailiff to deliver them, when the ſheriff comes to replevy them; and to that end, drives them to places unknown. Or when, without any words, they are ſo cloſe-hid, as that they cannot be replevied. Divers lords of hundreds, and courts-baron, have power to hold plea de *namio vetito*.

In ſuch caſe, the owner of the cattle may demand ſatisfaction for the injury, which is called *placitum de namio vetito*.

NAMUR *marble*. See LUCULLEUM *marmor*.

NANDI *arvatum*, in *Botany*, the name of a ſmall ſhrub which grows in the Eaſt Indies, the whole of which is baleſcent. The juice expreſſed from it, mixed with oil, eaſes pains of the eyes, if the head is anointed therewith; the root maſticated, and held in the mouth, eaſes the tooth-ach; and the ſame boiled in oil, makes a good ointment for all indiſpoſitions of the head, eſpecially pain; bruiſed, and taken in water, it kills worms; bruiſed with the juice of lemon, and put into the eyes, it removes ſpilms.

NANTES, or *ſcumming*, in the Linnæan ſyſtem, is the name of an order of animals under the claſs of AMPHIBIA; the characters of which are, that they are pinnated, and breathe by lateral branchiæ or gills. This order comprehends fourteen genera, and ſeventy-ſix ſpecies. To this order belong the PETROMYZON, RAJA, SQUALUS, &c.

NANTES, *edict of*, in *Eccleſiaſtical Hiſtory*, a famous edict drawn up at *Nantes* in the year 1598, by which Henry IV. granted to the profeſſors of the reformed or Proteſtant religion, the liberty of ſerving God according to their conſciences, and a full ſecurity for the enjoyment of their civil rights and privileges, without perſecution or moleſtation from any quarter. This edict reſtored and confirmed, in the fulleſt terms, all the favours that had ever been granted to the Proteſtants by other princes, and particularly by Henry III. To theſe privileges others alſo were added, which had never been granted, nor even demanded before: ſuch as free admiſſion to all employments of truſt, honour, and profit; the eſtabliſhment of courts and chambers, in which the profeſſors of the two religions were equal in number; and the permitting the children of proteſtants to be educated, without any moleſtation or conſtraint, in the public univerſities. This edict was revoked by Lewis XIV. at the inſtigation of the biſhops and Jeſuits, in the year 1685; the conſequence of which event was very beneficial to almoſt all the proteſtant countries of Europe; and more eſpecially to the commerce of Holland and England. The number of refugees, who on this occaſion fled from France, and carried their ſkill and induſtry in various manufactures to other countries, was, at a moderate computation, more than half a million.

NAPÆA, in *Botany*, a genus of the *monadelphia polyandria* claſs. Its characters are theſe: it hath male and hermaphrodite flowers on diſtinct plants; the male flowers have pitcher-ſhaped empalements of one leaf; the flowers have five oblong petals, which are connected at their baſe; and have many hairy ſtamina, which are joined at the bottom into a ſort of cylindrical column; the hermaphrodite flowers have the like empalement, petals, and ſtamina, as the male; and have a conical germen, ſupporting a cylindrical ſtyle, divided at the top into ten parts crowned by ſtigmas; the germen turns to an oval fruit, incloſed in the empalement, divided into ten cells, each containing one kidney-ſhaped ſeed. There are two ſpecies, natives of North America.

NAPE is uſed for the hind-part of the neck; by reaſon, perhaps, of the ſoft ſhort hair growing thereon, like the nap of cloth.

NAPELLUS. See ACONITE.

This plant is poiſonous in ſome places, and innocent in others. Its mortal quality increaſes with the heat of the climate, and goes off where that is ſmall. In the ſouth of France, it is a fatal poiſon; in Bretagne, they find the roots inoffenſive to the moſt tender conſtitutions; and farther north, they eat the leaves among their ſallad herbs, to get them an appetite, and find them a ſafe and wholeſome food.

It is ſaid the *napellus* may be ſo corrected by volatile ſalt of tartar, as to become innocent.

Dr. Hill makes the *napellus* a species of aconite.

NAPESCA, a name given by some to a species of *jujube*.

NAPHA, a name given by many of the writers in pharmacy to *orange-flower water*.

NAPHTHA, in *Natural History*, the name of a genus of fluid fossils, the characters of which are, that they are of a thin consistence, bright and pellucid, of a strong smell, very readily inflammable, and, when pure, burning away, without leaving any residuum.

The word in the original Chaldee signifies *filtrare, to ooze*, or *drip*; *naphtha*, according to Pliny, running like a kind of bitumen.

Of this genus there are only two species, the one commonly known by the name of *naphtha*, the other by that of PETROLEUM. The first is a pure and clear mineral fluid, of a much thinner consistence than any of the expressed oils of vegetables, and something thinner than the finer of the distilled ones; it is of a pale yellow, with a faint cast of brown among it, and is, indeed, of the very colour of the common brown amber used by the apothecaries. It is of a brisk, penetrating smell, something like that of the chemical oil of amber, but not so offensive; it is extremely inflammable, and is found floating on the waters of certain springs which break out at the sides of hills in Persia, Tartary, China, and other parts of the East, as in Chaldæa, particularly the place where stood the ancient Babylon; and found also in some provinces of Italy and France, particularly Auvergne, and near Ragusa.

Naphtha is found swimming on the surface of the water of some springs. It is usually of a black colour; though that found in certain springs about Babylon is said to be whitish.

That of France is soft and black, like liquid pitch, and of a fetid smell; that of Italy is a kind of petrol, or a clear oil, of various colours, oozing out of a rock, situate on a mountain in the duchy of Modena.

It seems very practicable, by means of this mineral fluid, and a proper acid, to make a sort of artificial amber, this being only a kind of fluid amber.

The second kind, commonly known by the name of *petroleum*, is a thin, subtile, and penetrating fluid, much thinner than the yellow *naphtha*, and as fine as the clearest distilled oils of vegetables. It is of a very strong and penetrating smell, and is of various colours; it is naturally of a clear, fine, and bright white, and nearly as pellucid as the purest spring water; but it is more frequently found brown, reddish, or blackish. It is produced in almost all parts of the world; England, France, and Germany, afford it in many places, but it is most plentifully found in Italy.

Naphtha is esteemed penetrating, resolutive, and vulnerary; but its virtues are but little known in medicine: its chief use is in lamps, &c. on account of its inflammability.

The Turks call the *naphtha earth fakin, black muscle*, to distinguish it from pitch. Vossius has an express treatise on *naphtha*, ancient and modern: he says, it is a flour of bitumen, and of more virtue than any other bitumen.

Naphtha has much the same medical virtues with PETROLEUM, only in a more remiss degree. In Persia, it is used externally on many occasions, and also given inwardly in colics, a few drops being the dose.

NAPIER'S, or NEPER'S *bones*. See NEPER'S *bones*.

NAPLES *yellow*, the common name in the colour shops of London, and among our painters, for the substance called GIALLOLINO.

NAPUS, *navew*, in *Botany*, a species of the *brassica*, or CABBAGE, of which there are two varieties, viz. the garden, or sweet *navew*, and the wild *navew*, or rape.

The roots of the garden *navew* are warmer and more grateful than those of the common turnep, and are said to afford, in their decoction, a liquor beneficial in disorders of the breast; as coughs, asthmas, and consumptions.

The seeds are roundish, of a reddish colour, and of an acrid and biting taste. They are accounted detersive, incisive, aperitive, and digestive, and said to be good in malignant fevers, and the small pox, and are an ingredient in the Venice treacle. In their quality they nearly resemble mustard-seed, to which they are inferior. See COLE-*seed*.

Nape, or *rapeseed*, is made from the seed of the *napus folesseris hibernis*, which grows on dry banks, and among corn, often called NAVETTE, and the oil *navetta oil*.

NAPUS, in *Natural History*, a name given to a species of *volutes*, approaching to the nature of the famous admiral shell, and more commonly known by the name of the *false admiral*, or *bastard* ADMIRAL.

NAPUT, in *Botany*, the name given by the Norwegians to a plant whose root is an excellent remedy for the colic. It grows plentifully in the northern parts of Norway, and is the constant remedy used by the miners for their colics, which are particularly severe. The taste is said to be agreeable, being at first chewing somewhat like a radish, but afterwards having the flavour of the garden angelica. Phil. Trans. N° 114.

NARCAPHTHON, in the *Materia Medica*, the name given by many to the bark called CASCARILLA.

NARCE, νάρκη, a torpor, stupor, or dullness of sensation; used either for a natural stupidity, or for that stupefaction of the senses brought on by medicines, to alleviate the violence of pains.

NARCISSITES, in *Natural History*, a name given by some authors to a species of ASTEROPODIUM, from its supposed resemblance to the flowers of the narcissus; others have called some of the coralloide fungites by that name, and others a species of echinites of the pileated kind.

It is, however, a name that none of them have any title to, since the resemblance will appear very small when nicely considered.

NARCISSOLEUCOIUM, in *Botany*. See SNOW-*drop*.

NARCISSUS, the *daffodil*, in *Botany*, a genus of the *hexandria monogynia* class. Its characters are these: the flowers are included in an oblong compressed spatha, or sheath, which tears open on the side, and withers; the flowers have a cylindrical funnel-shaped empalement of one leaf, which is spread open at the brim; they have six oval petals on the outside of the nectarium, which are inserted above their base, and six awl-shaped filamina fixed to the tube of the nectarium, terminated by oblong summits; they have a three-cornered, roundish, obtuse germen, situated below the flower, which afterwards turns to an obtuse, roundish, three-cornered capsule, with three cells filled with globular seeds.

Linnæus reckons thirteen species, and Miller more, comprehending a great number of varieties, which are much esteemed for their strong sweet scent; though it often proves too strong for some constitutions, and should not therefore be planted too close to habitations, nor the flowers be placed in rooms where company is entertained.

The common sorts of daffodil are generally placed in borders, where they afford an agreeable variety with other bulbous-rooted flowers. They are hardy, and will thrive in almost any soil or situation.

NARCOS, in *Ichthyology*, a name given by Joannes Cuba, and other writers, to the TORPEDO, or cramp-fish: a species of raia, distinguished by Artedi by the name of the *raia laevis*, the wholly smooth raia.

NARCOSIS, a stupefaction or insensible state, whether brought on by medicines, or happening from natural causes.

NARCOTICS, from the Greek ναρκωτικος, or ναρκωτικα, *narcotica*, in *Medicine*, opiates, or medicines that excite drowsiness and sleep. See OPIATE.

Narcotics, called also *hypnotics*, and *soporifics*, act by calming and diminishing the motion of the blood and spirits.

Authors are of various opinions as to the manner wherein *narcotics* operate: the ancients tell us, it is by their being cold in nature, whereby they stupify and deaden the spirits. Etmuller, after Willis, takes the animal spirits to be composed of a fluid, volatile salt; and thinks they are dissolved by the mixture of sulphurs and oils, wherewith *narcotics* abound. M. Andry's opinion is, that the salt of *narcotics* dissolves in any liquor whatever; and that their ramous branches, becoming thus disengaged from the salts, are embarrassed among one another, and thus stop the course of the blood and spirits. Others think, that *narcotics* close the orifices of the nerves, and thus block up the passage of the spirits. Lastly, Linden, in his treatise de Venenis, thinks, that the operation of *narcotics* is not the same in all; drowsiness being producible from a great variety of different causes. See SLEEP.

In disorders of the stomach and intestines, all things which induce a stupor are very cautiously, or never at all, to be exhibited; because no kind of medicines is so pernicious and injurious to the tone and motion of the nervous parts. To preserve health, and prevent diseases, nothing is so effectual as to maintain the tone, strength, and motion of what they call the *primæ viæ*, or first passages, because that most salutary excretion which is performed by stool, and discharges the fæces, which are the recrements remaining after digestion, or are collected from all parts of the body, depends chiefly thereon. Where this evacuation is suppressed, or else performed after a slow and remiss manner, a deluge of vicious humours is soon collected, and becomes the cause, as well as fomenter, of diseases. Now there is nothing which so effectually diminishes the peristaltic motion of the intestines, and suppresses intestinal excretion, as sedatives and anodynes, the truth of which is attested by experience; for as all remedies, so especially those which are

of

of a drastic quality, exert their efficacy first and principally upon the stomach and intestines.

NARDINUM *unguentum, ointment of spikenard*, an ointment greatly celebrated among the ancient writers in medicine. It seems to have been variously prepared, but always with a great number of aromatic ingredients, and always with *spikenard* for the basis.

Dioscorides says, that the *malabathrum*, or Indian leaf, was sometimes an ingredient in it, but that it was also sometimes made without it. It was generally, however, mixed with the *oleum balaninum*, or *ompbacinum*, impregnated with an addition of schœnanth; and to increase its fragrancy there were added, costus, amomum, myrrh, and balm of Gilead.

The finest was accounted that which was of a thin consistence, and very fragrant smell. It was said to be attenuating and detersive, but somewhat acrimonious; and was sometimes, for particular uses, reduced to a solid consistence with resin.

NARDUS, in *Botany*. See SPIKENARD.

NARDUS *rustica*, in *Botany*, a name attributed by some authors to the *asarabacca*, and by others to the *bacchoris Monspeliensium*.

NARES *piscium*. The *nostrils* in fish are placed so very variously, and have so many differences in number, figure, situation, and proportion, that they make a very essential series of characters, for distinguishing the genera and species one from another. In regard to number: 1. Some fish have them not at all, as the petromyzons. 2. Many fish have one *nostril* on each side, placed in the manner of those of birds and of quadrupeds, as the chamæpterus, &c. 3. Many have them placed two on each side, as the cyprini, perca, &c.

In regard to figure, they are, 1. In some round, as all four are in the gadi, and the two anterior ones in the conger, mackrel, &c. 2. Some are oval, as the posterior pair in the conger, &c. And, 3. Many are oblong.

As to their situation, they also differ much. 1. Some are placed very near the snout or rostrum, as the clupeæ; and the anterior tubulose foramina, in the conger or eel, are also of this kind. 2. In many kinds of fish they are placed near the eyes, as in the pike, the pearch, and the like. And, 3. In some they are placed as it were at a middle distance between the eyes and the end of the snout, as in the ammodytæ, or sand-eels, &c.

The *nares* of fish differ also in proportion: in those fishes which have two pairs of these holes, they are, 1. In some very near one another, so as almost to touch: they are thus placed in the cyprinus and clupea, &c. 2. They are placed at great distances, which is the case in the conger, the pearch, and many others. According to these variations, the *nostrils*, though a part in general very little attended to, yet become of notable use in distinguishing the species. Artedi.

NARIPUSORIA, a name given by authors to such medicines as were meant to be instilled into the nostrils, for disorders of the head and eyes.

NARINARI, the Brasilian name of a fish of the *aquila marina* kind, called by the Dutch *pijlstert* and *sticle*.

It is very large and flat, and the figure of its body is nearly triangular, its sides or wings being very broad, and larger; the head is very large, and has a furrow down its middle; the mouth is somewhat triangular, but rounded at the corners; it has no teeth; but in the place of them has a bone in the under part of its mouth in the shape of a tongue, of four fingers long, and a finger and half broad, and a smaller bone of the same shape in the upper part; between these it crushes its prey; the body is usually a foot and a half long, and the tail four feet; its flesh is finely flavoured.

The bones of this and the like fishes mouths, are the fossile *linguæ serpentis*.

NARIS *externus alius*, in *Anatomy*, a name given by Riolanus to one of the muscles of the nose, the use of which, he says, is to dilate the ala of the nose, without any elevation of the nose itself. It is called by Albinus the *compressor naris*, and by Winslow *the transversalis*, or *inferior nasi*. Cowper calls it the *elevator alæ nasi*, and Santorini the *transversus nasi*.

NARONICÆ *radix*, in the *Materia Medica*, a name given by some authors to the IRIS root.

NARRATION, in *Oratory* and *History*, a recital, or rehearsal of a fact as it happened, or as it is supposed to have happened.

Narration is of two kinds: either *simple*, and *historical*; as where the auditor or reader is supposed to hear or read of a transaction at second-hand: or *artificial*, and *fabulous*; as where their imaginations are raised, and the action is, as it were, re-acted before them.

The *narration*, according to the writers of rhetoric, makes the second part of a just speech, or harangue; viz. that immediately following the exordium.

It makes the whole of a history; abating for the occasional reflections, episodes, and digressions.

Cicero, Orat. Part. c. 9. requires four properties in a good *narration*; viz. perspicuity, probability, brevity, and sweetness.

The *narration* is rendered perspicuous, by observing the order of time, by using none but proper and known terms, with short, though full and explicit sentences, joined by proper particles, shewing their connection and dependence, and by reciting the action uninterruptedly, and with suitable transitions.

It is rendered probable, by the credibility of the narrator, by the simplicity and openness of the *narration*, by avoiding every thing far remote from the common sense and opinion of mankind, and by a precise detail of circumstances.

It is rendered brief, by taking it up no higher than is just necessary; nor fetching it back, as that impertinent author in Horace. *Ab ovo bellum Trojanum orditur ab ovo*; and by avoiding trivial circumstances.

Lastly, it is rendered sweet, pleasant, or entertaining, by using smooth, numerous, and well-sounding words; by arranging them, so as to avoid any hiatus, or gaping; by the greatness, novelty, and unexpectedness of the things related; and by enriching it with tropes and figures: as, frequent admirations, exclamations, interrogations, expectations, suspenses, surprising events, by grief, joy, fear, &c. See NUMBERS, CADENCE, and TROPE.

NARRATION, in *Poetry*, is used more particularly for the action, or event, that makes the subject of an epic poem.

P. Bossu observes, that the actions in poetry are equally susceptible of the two kinds of oratorial *narration*, and that each constitutes a particular species of poetry.

Those under the artificial, or active form, are now called *dramatic*.

And those only related by the poet, who here personates an historian, are called *epic*.

In the drama, the *narration* is the whole of the piece; in the epopœa, it is only a part, though in effect it is the principal part, and the main body of the poem. It is preceded by the proposition and invocation, which Bossu calls the preludes; and is frequently interrupted by the poet's speaking in person, demanding pardon, favour, &c.

The *narration* includes the whole action, episodified, with all its circumstances, and its ornaments.

It is in this part that the action is to be begun, carried on, and ended. It is this, which is to shew the causes of all that is related: in this the difficulties are to be proposed and resolved, and the persons, both human and divine, are here to shew their interests, their manners, and their qualities, by their actions, and their discourse; and all this is to be described with the beauty, the majesty, and force of verse, style, sentiments, comparison, and other ornaments proper to the subject in general, and to each thing in particular.

The qualities of the epic *narration* are, that it be agreeable, probable, moving, surprising, and active.

Horace speaks of the utile and dulce as on the same footing.

Bossu looks on the utile as an essential property; and the dulce as no more than an additional quality.

NARROW, in the *Manege*. A horse is said to *narrow*, when he does not take ground enough, or does not bear far enough out to the one hand or to the other. If your horse *narrows*, you must assist him with the inside rein, that is, you must carry your hand to the outside, and press him forward upon straight lines with the calves of your legs.

NARROW is also a term among bowlers. See BOWLING.

NARWAL, a name given to a fish of the whale kind, more frequently called the *sea*-UNICORN.

NASAL, something belonging to the nose, *nasus*. As, the nose-piece of a helmet, anciently called the *nasale*.

NASAL, in *Grammar*, &c. is applied to those sounds, or letters, in whose formation the nose is the principal organ; and particularly where the sound formed is passed through the nose.

In most English words, the sounds expressed by the characters *an*, *en*, *in*, *on*, *un*, are simple sounds, and proper *nasal* vowels. See M, N, &c.

NASALIA, in *Medicine*, a sort of remedies to be taken by the nose; called also ERRHINES.

NASAMMONITES, in *Natural History*, a name given by the ancients to a stone, which Pliny describes to have been of a blood-colour, variegated with veins of black. We know no stone which answers to this character at present, unless it be some of the agates, in a variegated state.

NASCALE, a sort of pessary, made of wool, cotton, or the

like, and introduced into the vagina, after being impregnated with proper ingredients.

NASDA, a word used by some medical writers for *napiform*, and seemingly a corruption of that word.

NASEBERRY-*tree*, in *Botany*. See *Star*-APPLE.

NASI *os*, in *Anatomy*, a thin bone, making the upper part of the NOSE.

NASITAS, a word used by some authors to express a speaking through the nose.

NASTOS, in *Botany*, a name by which Clusius and some other authors have called the reed, of which the common walking canes are made, which is the *arundo fortis* of other writers.

NASTURTIUM, in *Botany*. See CRESSES.

NASTURTIUM *aquaticum*. See MINT.

NASTURTIUM *Indicum*. See *Indian* CRESSES.

NASUS, in *Ichthyology*, the name of a fresh-water fish, common in the Rhine, the Danube, and most of the large rivers in Germany, though unknown in England, and called by different authors the *fimus*, *favetta*, and *phoxy-rynchos*.

Its general size is between six and twelve inches in length; in shape and colour it much resembles our chub. It is a loose and insipid-tasted fish, and very full of bones; they spawn in May, at which time the males are rougher than at any other season, and have their heads speckled with white spots, like the English rudd. At this time also they swim together in immense shoals, and the fishermen have sometimes caught two or three thousand of them in one night.

NATALIS, NATALIS *dies*, *or* NATALITIUM, properly signifies a man's birth-day. See NATIVITY.

The word was first used among the heathens, to signify the feast held on the anniversary of the birth-day of an emperor; whence it came, in time, to signify any sort of feast. And, accordingly, in the Fasti, we meet with *natalis Solis*, *natalis Isidis*, &c.

The primitive Christians, finding the word thus established, used it in the same manner; and hence we meet in the ancient martyrologists with *natalis cœnæ*, for the feast of the Supper, or Maundy-Thursday; *natalis cathedræ*, for the postification of St. Peter; *natalis* or *natalitium*, of such a church, for the feast of the dedication.

The word *genethlion* is used by the Greeks in the same sense as *natalis*, or *natalitium*, among the Latins.

NATALITII, *lusi*, NATALE *games*, were games introduced on the anniversaries of the birth-days of great men.

NATAL *ring*, *annulus* NATALITIUS, was a ring only worn on the birth-day.

NATANT *leaf*, in *Botany*. See LEAF.

NATES, in *Anatomy*, a term expressing those two fleshy posterior parts of the body, popularly called the *buttocks*; by the Latins *clunes*, or *nates*.

NATES *cerebri*, are two circular protuberances of the BRAIN, situate on the back-side of the MEDULLA *oblongata*, near the cerebellum.

NATION, a collective term, used for a considerable people, inhabiting a certain extent of ground, inclosed within fixed limits, and under the same government.

Each *nation* has its peculiar character; and it is proverbially said, *Light as a Frenchman*, *Wary as an Italian*, *Grave as a Spaniard*, *Serious as an Englishman*, *Fierce as a Scotchman*, *Drunken as a German*, *Idle as an Irishman*, *Deceitful as a Greek*, &c.

NATION is also used, in some universities, for a distinction of the scholars, and professors of colleges.

The faculty of Paris consists of four *nations*; viz. that of France, that of Normandy, that of Picardy, and that of Germany; which are again, excepting that of Normandy, distinguished into tribes; and each tribe has its deacon.

The German *nation* comprehends all foreign *nations*, English, Italian, &c.

When the procureur of the French *nation* speaks in public, his style is, *Honoranda Gallorum natio*; he of Picardy says, *Fidelissima Picardorum natio*; he of Normandy, *Veneranda Normannorum natio*; he of the *nation* of Germany, *Constantissima Germanorum natio*.

NATIONS, *law of*. See LAW.

NATIONAL *debt*, is the debt due by the state to the public, on account of monies borrowed and funded for defraying the charges of government.

In order to trace the origin of this debt, it is proper to be considered, that after the Revolution, when our connections with Europe introduced a new system of foreign politics, the expences of the nation, not only in settling the new establishment, but in maintaining long wars, as principals on the continent, for the security of the Dutch barrier, reducing the French monarchy, settling the Spanish succession, supporting the house of Austria, maintaining the liberties of the Germanic body, and other purposes, increased to an unusual degree; insomuch that it was not thought advisable to raise all the expences of any one year by taxes to be levied within that year, lest the unaccustomed weight of them should create murmurs among the people. It was, therefore, the policy of the times to anticipate the revenues of their posterity, by borrowing immense sums for the current service of the state, and to lay no more taxes upon the subject than would suffice to pay the annual interest of the sums so borrowed; by this means converting the principal debt into a new species of property, transferrable from one man to another at any time, and in any quantity; a system which seems to have had its original in the state of Florence, A. D. 1344, which government then owed about 60,000*l.* sterling; and being unable to pay it, formed the principal into an aggregate sum, called metaphorically a mount or bank, the shares whereof were transferrable like our stocks, with interest at 5 *per cent.* the prices varying according to the exigencies of the state. This laid the foundation of what is called the *national debt*; for a few long annuities created in the reign of Charles II. will hardly deserve that name. And the example then set has been so closely followed during the long wars in the reign of queen Anne, and since, that the capital of the *national debt* (including a valuation of the long and short and life-annuities, and the unfunded debt) amounted in 1761, to at least two hundred and eighteen millions, to pay the interest of which, and the charges for management, amounting annually to upwards of seven millions and a half, the extraordinary revenues mentioned under the article REVENUE (excepting only the land-tax, and annual malt-tax) are in the first place mortgaged, and made perpetual by parliament; but still redeemable by the same authority that imposed them; which, if it at any time can pay off the capital, will abolish those taxes, which are raised to discharge the interest. See FUND. Blackft. Comm. book i. p. 328.

NATIONAL *synod*. See SYNOD, and CONVENTION.

NATIVE is applied to a person considered as born in a certain place, or deriving his origin from it.

The more accurate writers distinguish between a *native* of a place, and one *born* there. Born signifies no more than the having been there produced, or brought into the world, whether that were the proper country or habitation of the parents, or whether they were there only by accident, as strangers, &c. Whereas *native* refers to the proper mansion or residence of the parents, and the family, and where the person has his education.

And hence a person may be a *native* of one place, and born at another: thus Jesus Christ is called a Nazarite, and Galilean, as a *native*, though he was born at Bethlehem in Judah.

NATIVE, *nativi*, in our *Ancient Law Books*, signified a person who was born a slave or villain.

By which he differed from one who had sold himself, or became a slave by his own deed, who was called a *homo*. See VILLAIN.

NATIVI *tenentes*, in our *Old Law-Books*, are those freemen who hold *native* land; i. e. land subject to the services of *nativi*. Spelm.

NATIVI *de stipite*, were villains or bond-men by birth or family. There were also *nativi conventionarii*, who were villains by contract or covenant. *Servi nimis alti natura, alii facti, alii empliones, alii redemptione, alii sua vel alterius datione.* LL. Hen. I. cap. 76

In Cornwall it was a custom, that if a freeman married *nativam* (that is, a neif) and brought her *ad liberum tenementum, & liberum herum*, and had two daughters, one of them was free, and the other a villain. Bract. l. 4. c. 21. See NEIF.

NATIVITY, *nativitas*, or *natal day*; the day of one's birth. The term is chiefly used in speaking of saints, &c. The *Nativity* of St. John Baptist, celebrated in the Romish church with great solemnity on the twenty-fourth of June; the *Nativity* of the Holy Virgin, a feast established by pope Sergius I. who was advanced to the see of Rome, in 687, and observed on the eighth of September, &c. When we say absolutely the *Nativity*, it is understood of that of Jesus Christ, or the feast of Christmas. See FEAST, CHRISTMAS, &c.

NATIVITY, *nativitas*, in *ancient Law Books*, signifies bondage, or servitude.

NATIVITY, in *Astrology*, the theme or figure of the heavens, and particularly of the twelve houses, at the moment when a person was born; called also the HOROSCOPE.

Casting the *nativity*, or by calculation seeking to know how long the queen should live, &c. was made felony, an. 23 Eliz. c. 2.

NATIVO *habendo*, in *Law*, a writ directed to the sheriff, for a lord who claimed inheritance in any villain, when his villain was run away from him, for the apprehending and restoring him to the lord.

NATIX, in *Natural History*, a name given by some old writers to the *neritæ*.

NATRIX,

NATRIX, in *Botany*, the name given by Rivinus to a genus of plants, nearly allied to the anonis, and comprehended with it in one genus by Linnæus, under the name of anonis. See REST-*harrow*.

NATRIX, in *Zoology*, the name of the common or water-snake, called also *torquata*, from the ring about its neck. It is much longer and larger than the viper, and is no water animal, properly speaking, but a land one, which being able to swim very well, often takes the water to hunt about for frogs, which are its principal food. It grows to be much longer and larger than the viper, and does not bring forth five young ones, but great numbers of eggs, which it lays in dunghills to be hatched by the warmth of the place, or by the heat of the sun.

It is very common in bushy places, and near waters, and in winter finds holes in the banks of ditches, or about the roots of trees, where it lies torpid the whole winter. It has no poison, and may be safely taken up and played with, never so much as attempting to bite. It feeds on many small insects, sometimes on vegetable substances, and oftener on frogs, mice, &c.

Its back is of a sort of dusky earth colour, and its belly variegated with black and a bluish white, but near the head almost wholly white, having only a few small spots of black at the sides, the colour growing darker toward the end of the tail; and near the end, the middle part of all the scales is black, and their extremities only of a bluish white; the whole belly is covered with long parallel scales, placed transversely. The back and sides are covered with small scales, and are variegated with several streaks and spots of black; there are more than eighty transverse black lines running from the back to the sides, and beside these, two other rows of smaller, in form of spots, near the middle of the back; the head is covered with large scales of a duskier colour than those of the rest of the body, and the upper jaw is white on each side, with four or five slight lines of black running across it; its chin is yellow, and is composed of two large spots of that colour, placed one on each side of the neck, or at each angle of the jaws, between which is placed a large triangular spot of a deep black, with its top directed toward the tail; it has none of those long canine teeth of the viper and other poisonous serpents, by means of which the poison is conveyed into the wound, but only two rows of small serrated teeth, designed by nature for no other use than eating its food.

It may not be judged improper to have been thus particular in the description of this species, as it is well to know what of the snake kind are, and what are not to be feared; and as the apothecaries and others, for want of these characters, often buy this common snake under the name of the viper. Ray.

NATRON, or ANATRON, in *Natural History*, a brownish kind of salt, taken out of a lake of stagnant water, in the desert of Nitria, in Egypt.

It is much of the nature of nitre; whence it is by many called *Egyptian nitre*, and is supposed to be the proper nitre of the ancients.

The lake whence it is obtained, is six or seven acres in extent, and lies about thirty miles west-and-by-south from Terana, and about the same distance north from the pyramids: from the bottom of this lake the salt called *natron* arises to the surface of the water, and is there condensed, by the heat of the sun, into the hard and dry form in which it is sold.

If four ounces of the water of the *natron* be examined by evaporation in a glass vessel, placed in a sand-heat, there will arise, as soon as it becomes warm, a sort of scum to the top; this being taken off, another instantly succeeds, and so on, so long as any water remains in the glass.

The salt, thus scummed off, is the same in all respects with the *natron*, or the Smyrna soap earth; being a fixed alkali, fermenting with acids, and boiling into soap with oil. This icy scum is the same as that called by Pliny *flos salis*, and seems to be the same with that which Herodotus says the Egyptians made use of in the preparation of their mummies. The ancients have attributed great virtues to the salt of this lake; and this being called *nitrum*, as a short name for *nitrium sal*, we have had some who have supposed the salt which we call *nitre*, to be the same, and these people have wondered that they did not find the same virtues in our *nitre*.

The mineral waters of all parts of the world seem to contain more or less of this salt, and to owe their virtues in a great degree to it; and, probably, it might be no small improvement to physic, to bring it more into the present practice. Molenbroch recommends it greatly in the stone; and it may be the more probably used, as all alkali salts are known to be good in that distemper. Some add to this, that it seems qualified to dissolve stony substances, it being of so piercing and penetrating a spirit, than no rock, or stone, is found about the lake from the waters of which it is procured. Phil. Trans. N° 160.

We learn from the account of the Voyages to the South Seas, published by Dr. Hawkesworth, that this salt, which is thought to be the true *natrum*, or nitrum of the ancients, is found in large quantities on the top of the mountain Teneriffe.

It is used in the whitening of linen; but it burns them, if not corrected by a mixture of ether.

The *natron* of Egypt, as described by Pliny, Matthiolus, and Agricola, is an alkali salt perforated in manner of a sponge, and of a lixivial taste.

Its principles Dr. Leigh takes to be chiefly two; viz. a sea-salt, and an urinous salt.

The first, he takes it for granted, it receives from the earth; the second, from air.

Dr. Huntington, who was on the spot, says the *natron* is thought to rise from the bottom of the lake; where, by the heat of the sun, it is condensed, and hardened into the form we see it in; but his opinion is, that it is rather separated by the sun from the water.

M. de la Chambre adds, that three or four days before the Nile begins to overflow, there falls a certain dew, of a fermentative virtue, insomuch as to deserve a place exposed to it; and that at the same time the *natron* dies.

Hippocrates, Galen, Matthiolus, Dioscorides, &c. mention it as of use in physic; and M. de Clos is even of opinion, all the mineral waters of France are impregnated with this kind of nitre; and that it is hence they derive their medicinal virtues.

It is of singular efficacy in fertilizing of ground; which Dr. Leigh accounts for, by supposing its volatile particles heated by some subterraneous fire, or by the warmth of the sun; and thus readily made to ascend up the minute tubes of plants, and carry with them the juices of the earth.

This nitre is distinguished from the common nitre, or saltpetre, by its fermenting with acids, which saltpetre will not do; by its volatile spirit, by its lixivial smell, and the clammy insipid substance it yields, &c. It agrees with saltpetre, in that, by dropping spirit of sulphur upon it, it shoots into pyramidal crystals. Dr. Leigh thinks it comes nearer sal ammoniac than saltpetre.

It is naturally of a dusky white; but is sometimes found of a brown colour, and sometimes of a fine deep red. This is its purest state; but besides this, it is frequently found in form of powder mixed with dirt, and arising in little hillocks on the surface of the ground. It is of an acrimonious pungent taste, and is more like the alkaline salts produced by burning vegetables, than any of the native salts. It dissolves in a very small quantity of water, and ferments violently with aqua fortis, or any other weaker acid menstruum.

It is found in great plenty in Sindy, a province in the inner part of Asia, and in many other parts of the East, and might be had in any quantities. Perhaps it would be worth considering as a branch of commerce, as it would supply the place of pot-ashes in the making soap and glass, as the same author has tried.

The characters recorded of the *nitre* of the ancients are, 1. That it would ferment with vinegar; and, 2. That it had an abstersive quality. These we have from the scriptures; and the rest were, that it was of an acid taste; that it was found native in the eastern parts of the world; that it served in the place of soap; and that with sand it would make glass. All these properties this salt has; and it may be added, that no other native salt has them. Hill's Hist. of *Foss.* p. 386 to 389.

It is a very remarkable property of this salt, that though in itself an alkali, and fermenting very violently with acids in its native dry state, yet in solution it does not ferment with them at all. If indeed oil of vitriol, or some other acid, be added to the solution of *natron* while turbid, that is, while some of the particles of the salt remain yet whole in it, the two liquors will ferment violently; but if the solution be set by till wholly clear, the same acid will cause no effervescence in it; but the same solution, evaporated to a third part, will again ferment with that or any other acid, the particles of the salt at that time being got together again, and meeting the acid as in their solid form.

This salt contains a volatile alkali, absorbed from the air, and embodied in it. Its other principle seems a marine salt, which it may receive either from the earth, or from salt springs, or sea water, according to the different places where it is found.

NATTA, or NATA, alias written *nasa*, *nadis*, and *nappa*, in *Surgery*, a large fleshy excrescence or tumor arising in several parts of the body.

Blancard defines it, a large, soft, painless, colourless tu-

ther, arising usually on the back, sometimes on the shoulders, and other parts. Its root is very small; yet it grows so prodigiously, that it sometimes equals a melon, or gourd.

Nurse often eft appear on the neck, much after the manner of ruptæ.

They are of the œdematous kind, and are to be extirpated by incision, and their return prevented by red precipitate vitriol, or burnt alum, strewed on the place.

Bartholine mentions a lady, who cured herself of a *nurse*, by biting it off.

NATURAL, fomething that relates to nature; that arifes from a principle of nature; or is conformable to the ordinary courfe and order of nature.

When a ftone falls downwards, we vulgarly fay it does it by a *natural* motion; but if it be thrown upwards, its motion is faid to be violent.

Water fufpended in a fucking pump is faid to be out of its *natural* place: cures wrought by medicines, are *natural* operations; but the miraculous ones wrought by Chrift, *fupernatural*. See MIRACLE, &c.

NATURAL *cauſe*. See CAUSE.

NATURAL *children*, are thofe born out of lawful wedlock. See BASTARD.

NATURAL *day*. See DAY.

NATURAL *year*. See YEAR.

NATURAL *faculty*. See FACULTY.

Quincy defines *natural faculty* to be that power arifing from the blood's circulation, which is conſpicuous in all the ſecretions performed within the body; that ſecretion alone excepted, which is made at the origin of the nerves.

NATURAL *functions*, in the *Animal Oeconomy*. See FUNCTION.

NATURAL *hiſtory*, a deſcription of the natural products of the earth, water, or air; viz. beaſts, birds, fiſh, metals, minerals, and foſſils; together with ſuch extraordinary phenomena as at any time appear in the material world; as meteors, monſters, &c.

Beſides *General Natural Hiſtories*, as thoſe of Pliny, &c. there are *particular* ones; and thoſe of two kinds. The firſt, thoſe which only conſider one kind of things; ſuch as the Hiſtory of Shells, by Dr. Liſter; of Fiſhes, by Willughby; that of Birds, by the ſame; that of Plants, by Ray; thoſe of Inſects, by Swammerdam, and Mouffet; that of Animals, by Gefner; that of Foſſils, by Agricol, Mercatus, &c.

The ſecond, thoſe which conſider the ſeveral kinds of natural things found in particular countries, or provinces; as the *Natural Hiſtory* of Dauphiné, by Chorier; the *Natural Hiſtory* of the Antilles, by F. Du Tertre, and M. Loüvilliers De Poincy; thoſe of Oxfordſhire, and Staffordſhire, by Dr. Plott; that of Lancaſhire, by Leigh; of Northamptonſhire, by Morton; that of the Weſtern Iſlands, by Martin, &c.

The *natural hiſtory* only of one particular place, is a ſubject very extenſive in its materials, and not to be ſet about without great care and circumſpection. Mr. Boyle has favoured the world with a liſt of the heads under which to arrange things, and what to enquire after on ſuch an occaſion.

The general heads under which he comprehends the articles of this hiſtory are four; the things which regard the heavens, the air, the waters, and the earth.

Of the firſt claſs are the longitude and latitude of the place; the length of the longeſt and ſhorteſt days and nights; the climates, parallels, &c. what fixed ſtars are ſeen, and what are not ſeen there.

About the air may be obſerved, its temperature, as to the firſt four qualities, and the meaſure of them; its weight, clearneſs, refractive power; its ſubtlety or coarſeneſs; its abounding with or wanting an eſurine ſalt: its variations according to the ſeaſons of the year, and the times of the day: what duration the ſeveral kinds of weather uſually have: what meteors it is moſt or leaſt apt to breed; and in what order they are generated, and how long they generally laſt: what winds it is moſt ſubject to; whether any of them ſtated or ordinary: what diſeaſes are ſaid to be epidemical, or depending on the ſtate and condition of the air: what other diſeaſe it is ſubject to; wherein the air may be ſuppoſed to have ſome ſhare: what is the moſt ſalubrity and inſalubrity of it, and what ſorts of conſtitutions it agrees with, what it does not.

About the waters, it may be proper to obſerve the ſea, its depth, tides, current, ſaltneſs, and other qualities: next, the rivers will come under conſideration, their depth, length, courſe, inundation, and the goodneſs or badneſs of their waters, with their gravity, and other peculiar qualities. After theſe, the lakes, ſprings, ponds, &c. are to be conſidered, eſpecially the mineral waters, their kinds, qualities and virtues, and the manner of trying them. The inhabitants of the waters may follow here; and the particular kinds of fiſh that are found there, whether of the ſea or rivers, are to be mentioned, with an account of their ſtores, bigneſs, goodneſs, ſeaſons of perfection, haunts, peculiarities of any kind relating to them, and the manner of taking them, eſpecially when there is any thing ſingular in it.

The things relating to the earth, are laſt to be examined: theſe are, firſt the earth itſelf, then its inhabitants and its various productions, whether external or internal. In the earth itſelf may be obſerved, its dimenſions, ſituation eaſt, weſt, north, and ſouth; its figure; its plains and valleys, their extent; its hills and mountains, and the height of the talleſt, both in reference to the neighbouring valleys and plains, and to the level of the ſea; as alſo whether the mountains lie ſcattered, or are diſpoſed in ridges; and, if of the latter kind, whether they run eaſt, weſt, north, or ſouth. What promontories alſo, and what fiery or ſmoking hills it has, if any; whether the country be coherent, or much broken into iſlands; what the magnetical declination is in ſeveral places, and the variation of that declination in the ſame place; and if thoſe be conſiderable, what may be conjectured as the occaſions of them, whether the vicinity of iron-mines, of ſubterranean fires, or what elſe. What the nature of the ſoil is, whether clayey, ſandy, or of good mold; and what vegetables, plants, and trees beſt agree with it and ſucceed in it, what worſt. By what particular contrivances the inhabitants improve the advantages, or remedy the diſadvantages of the ſoil; and what hidden qualities the ſoil may have. The inhabitants of the earth are then to be conſidered, both natives, and ſtrangers that have been long ſettled there; and in particular, their ſtature, colour, features, ſtrength, agility, or defects of theſe; and their complexion, hair, beauty, and the like; their diet, inclinations, and cuſtoms, ſo far as they are not owing to education: the fruitfulneſs or barrenneſs of the women; their hard or eaſy labours: the diſeaſes they are moſt ſubject to, and any remarkable ſymptoms attending them.

As to the external productions of the earth, the enquiries are to be theſe: what graſſes, grains, and fruit it beſt produces: the herbs, flowers, and timber trees; and the coppices, groves, foreſts, and woods the country has, or wants: what peculiarities are obſervable in any of them; what ſoils they moſt like or diſlike, and with what culture they thrive beſt. Then what animals the country has or wants; both as to wild beaſts and birds of prey, and as to poultry and cattle of all ſorts; and particularly, if they have any animals that are not common, or any thing particular in thoſe they have. After thoſe, the ſubterranean ſtores are to be examined; what minerals the earth affords, and what it wants: then what quarries of ſtone, and in what manner they lie: what clays and earths are found there; as, clays, marles, fuller's earths, earths for tobacco-pipes, earth for potter's wares, medicinal earths: what other mineral productions it yields, whether coals, ſalt mines, or ſalt ſprings, alum, vitriol, ſulphur, &c. What metals the country yields, with a deſcription of the mines of them; their depths, numbers, ſituations, figns, waters, damps, quantities of ores, goodneſs of the ores, and the ways in uſe for reducing them to metals.

To theſe general heads ſhould be added, inquiries into traditions in the country, of any thing relating to it, whether peculiar to it, or only more common there than elſewhere; and where theſe require learning or ſkill in the anſwerer, the utmoſt care is to be taken to put the people in a way to give their accounts in a ſatisfactory manner; for a falſe or bad account of any thing is always much worſe than no account at all. Phil. Tranſ. N° 11.

NATURAL *horizon*, is the ſenſible or phyſical HORIZON.

NATURAL *inclination*, are thoſe tendencies or motions of the mind, towards things ſeemingly good, which are common in a greater or leſs degree, to all mankind. See APPETITE.

Natural inclination, according to F. Malebranche, is the ſame thing, with regard to minds, that motion is with regard to bodies: and as all the varieties in the material world ariſe from the ſeveral motions of bodies, ſo do all thoſe of the intellectual world from inclinations: and as all motions are the reſult of impreſſions immediately communicated by the finger of the Creator; ſo all inclinations are certainly nothing elſe but continual impreſſions of the will of the Creator on that of the creature; and muſt therefore, of neceſſity, be agreeable to him; and therefore can naturally have no principal end but his glory; nor any ſecondary one but their own preſervation, and

that of others, both ſtill with regard to his will, who gave them being.

Now as, properly ſpeaking, there is but one love in God: viz. that of himſelf; ſo he only impreſſes one love or deſire in us; which is that of good in the general. It is this general love, or deſire, is the principle of all our particular ones; as, in effect, it is the will itſelf; the will being defined to be a continual impreſſion of the Author of nature, which carries the mind of man to good in general.

But the impreſſion towards good in the general doth not only proceed from God, but alſo all our inclinations to particular goods; as, v. gr. ſelf-preſervation, &c.

NATURE, *laws*. See *Laws of* NATURE.

NATURAL *liberty*. See *Civil* LIBERTY.

NATURAL *magic* is that which only makes uſe of natural cauſes. See MAGIC.

NATURAL *philoſophy*, that ſcience which conſiders the powers of nature, the properties of *natural* bodies, and their mutual action on one another: this is otherwiſe called *phyſics*.

NATURAL, in *Heraldry*, is uſed where animals, fruits, flowers, &c. are blazoned with the colours they naturally have, though different from the common colours of heraldry: and this is to prevent the armory's being accuſed of falſity, when blazoned with the names of colours unknown in heraldry.

NATURAL, in *Muſic*, is ſometimes uſed for DIATONIC.

It is alſo applied to a ſong, the notes whereof move eaſily and gracefully, giving the performer as little trouble as poſſible; and when it is not carried too high, or ſunk too low, whereby the voice or inſtrument is in no wiſe forced or ſtrained.

NATURAL is alſo ſometimes uſed for phyſical. In which latter ſenſe, *natural muſic* is that performed by *natural* organs, or vocal muſic; in contradiſtinction to artificial, or inſtrumental. See MUSIC.

Natural muſic is more peculiarly uſed to denote a ſong that proceeds in the *natural* order of the notes, without flats or ſharps.

NATURAL *ſcale* is that produced by the natural and eſſential chords of the mode. See HARMONY.

NATURAL *note* is uſed in oppoſition to flat and ſharp notes, which are called *artificial notes*. See NOTE, SCALE, &c. The *natural note* B, is uſed to contradiſt thoſe flats and ſharps that are ſet at the beginning of a ſtaff; and, in ſuch caſe, you muſt take the *natural note* as it is in the gamut.

NATURAL is alſo uſed for ſomething coming immediately out of the hands of nature. In which ſenſe it ſtands oppoſed to factitious or artificial, which ſignifies ſomething wrought by art.

Biſhop Wilkins obſerves, that there appears a world of difference between *natural* and artificial things, when viewed with microſcopes: the firſt ever appear adorned with all imaginable elegance and beauty; the latter, though the moſt curious in their kind, infinitely rude, and unhewn. The fineſt needle appears a rough bar of iron, and the moſt accurate engraving, or imboſſment, as if done with a mattock, or trowel.

NATURALIST, a perſon who has ſtudied nature, and is well verſed in natural bodies, eſpecially in what relates to metals, minerals, ſtones, vegetables, and animals.

Ariſtotle, Ælian, Pliny, Solinus, and Theophraſtus, were the greateſt *naturaliſts* among the ancients; but they fell into abundance of errors, which have been corrected by the happy induſtry of the moderns. Aldrovandus is the moſt copious, but not the moſt accurate, of the modern *naturaliſts*: his work is in thirteen volumes in folio. The characters and works of Linnæus are well known.

NATURALIZATION, in *Law*, the act of naturalizing an alien, or putting him into the condition of a naturalborn ſubject, and inſtilling him to the rights and privileges thereof.

In France, *naturalization* is the king's prerogative: in England, it is only done by act of parliament.

But no perſon can be *naturalized*, unleſs they have received the ſacrament within one month before the bringing in of the bill, and taken the oaths of allegiance and ſupremacy in the preſence of the parliament. A perſon who is naturalized may have lands by deſcent, as heir at law, as well as obtain them by purchaſe; but he is diſabled from being a member of the privy council, or parliament; as from holding offices, 7 Jac. I. cap. 2. 12 Will. III. cap. 2. All children born out of the king's dominions, whoſe fathers were or are ſubjects of this kingdom at the time of their birth, are adjudged to be naturalborn ſubjects of this realm, except children of parents attainted of treaſon, or that are in the actual ſervice of a foreign prince at enmity with us. 4 Geo. II. cap. 21. Every foreign ſeaman who, in time of war, ſerves two years on board an Engliſh ſhip, is, *ipſo facto*, *naturalized*, 13 Geo. II. cap. 3. And all foreign Proteſtants and Jews, upon their reſiding ſeven years in any of the American colonies, without being abſent above two months at a time, or ſerving two years in a military capacity there, are, upon taking the oaths, *naturalized* to all intents and purpoſes, as if they had been born in this kingdom; and therefore are acceſſible to all ſuch privileges and no other, as Proteſtants or Jews born in this kingdom are intitled to.

In France, Swiſs, Savoyards, and Scots, need not any *naturalization*; being reputed regnicoles, or natives.

NATURALS, *les* NATURELS, in *Medicine*. In every animal, however ſick and diſeaſed, there is ſtill remaining ſome degree of life and ſtrength; and the cauſes and effects of each. Theſe are called *naturals*, natural things, or things according to nature; and ſometimes barely nature; in contradiſtinction to *non-naturals*.

NATURE, NATURA, is a term variouſly uſed. Ariſtotle has a whole chapter wrote expreſly to enumerate the various acceptations of the Greek word φύσις, rendered, in Engliſh, *nature*: and, among Latin writers, the different acceptations are ſo many, that a certain author reckons up fourteen or fifteen. Mr. Boyle in a peculiar treatiſe of the vulgarly received notion of *nature*, gives us eight principal ones.

NATURE, then, is ſometimes uſed for the ſyſtem of the world; the machine of the univerſe; or the aſſemblage of all created beings.

In which ſenſe we ſay, the Author of *nature*: the ſun is called the eye of *nature*, becauſe he illuminates the univerſe; and the father of *nature*, becauſe he warms the earth, and makes it fruitful. And thus we ſay of the phœnix, or a chimera, that *there* is no ſuch thing in *nature*.

Inſtead of the word *nature* in this ſenſe, Mr. Boyle, to avoid ambiguity, and abuſe of the word, wiſhes to have WORLD, or *univerſe*, ſubſtituted.

NATURE, in a more confined ſenſe, is applied to each of the ſeveral kinds of beings, created and increated; ſpiritual and corporeal.

In which ſenſe, we ſay, human *nature*, meaning all men together who poſſeſs the ſame ſpiritual, reaſonable ſoul; angelical *nature*; the divine *nature*, &c.

In this ſenſe, the ſchoolmen ſay, *natura naturans*, & *natura naturata*, ſpeaking of God, who is the *natura naturans*, as giving being and *nature* to all others; in oppoſition to the creatures, who are the *natura naturata*, as receiving their *nature* from the hands of another.

NATURE, in a ſtill more reſtrained ſenſe, is uſed for the eſſence of a thing; or that which ſchoolmen call the quiddity thereof, that is, the attribute which makes it what it is.

In which ſenſe, the Carteſians ſay, it is the *nature* of the ſoul to think; and that the *nature* of matter conſiſts in extenſion.

And here the word *eſſence* Mr. Boyle would have obtain, in lieu of *nature*.

NATURE is more particularly uſed for the eſtabliſhed order and courſe of material things; the ſeries of ſecond cauſes; or the laws which God has impoſed on the motions impreſſed by him.

In which ſenſe it is we ſay, phyſics is the ſtudy of *nature*; *nature* makes the night ſucceed the day; *nature* has rendered reſpiration neceſſary to life, &c.

Thus St. Thomas defines *nature* a kind of divine art, communicated to beings, which carry them to the end they are determined for. In which ſenſe, *nature* is nothing elſe but that concatenation of cauſes and effects, or that order and œconomy which God has eſtabliſhed in the parts of his creation.

In this ſenſe, too, we ſay, miracles are effects above the powers of *nature*: art is ſaid to force or ſurpaſs *nature*, by means of machines; in regard theſe produce effects which exceed what we find in the common courſe of things.

NATURE, again, is taken for an aggregate of powers belonging to any body, eſpecially a living one.

In which ſenſe phyſicians ſay, *nature* is ſtrong, weak, or ſpent; or that, in ſuch a diſeaſe, *nature* left to herſelf will perform the cure.

NATURE is ſtill more ſtrictly uſed for the action of providence, the principle of all things; or that ſpiritual power, or being, which is diffuſed throughout the creation, and moves and acts in all bodies, and gives them certain properties, and produces certain effects.

In this, which Mr. Boyle conſiders as the moſt uſual ſenſe, *nature* is nothing elſe but God, acting himſelf, and according to certain laws he himſelf has fixed.

This ſeems pretty agreeable to the opinion of many of the ancients, who make *nature* the god of the univerſe, Thales, who preſides over, and governs all things; though others owned this an imaginary being, and by *nature* meant

meant no more than the qualities, or virtues, which God has given his creatures, and which their poets and orators took occasion of personifying.

F. Malebranche says, that the *nature* so much talked of in the schools is fit for nothing but to lead us back to idolatry; the ancient heathens fiercely understanding something, which, without being God, acts continually throughout the universe.

Thus the idol *nature* must be an actual principle, which, in concurrence with God, is the next and immediate cause of all the changes which befal matter. Which seems to fall in with the opinion of the *anima mundi*; as if *nature* were a substitute of God, or a collateral cause with God, or a middle being between God and created things. See PLASTIC.

Aristotle defines *nature, principium & causa motus & eius in quo est primo per se, & non per accidens*: a definition so obscure, that none of his commentators, with all their glosses, have been able to render it intelligible.

This principle, which the Peripatetics called *nature*, they supposed to act necessarily; and to be therefore destitute of knowledge, or liberty. See NECESSITY.

Thus, also, the Stoics conceived *nature* as a certain spirit or virtue diffused throughout the universe, which gave every thing its motion; so that all must be dragged away by the invariable order of a blind *nature*, and an inevitable necessity.

In speaking of the action of nature no more is to be understood, but that bodies act on one another, in a manner agreeable to the general laws of *motion* which the Creator has established.

In this lies the mystery of that great word, which is only a compendious way of expressing the action of all bodies: but the mechanism of bodies would, perhaps, better express what is here meant by *nature*.

Some, Mr. Boyle observes, will have the *nature* of a thing to be only the law that it receives from the Creator, and according to which it acts on all occasions. But this is an improper and figurative expression.

The same author proposes a notion of *nature* as more fit than any yet given, to pass from the principal one of *nature*; with regard to which many axioms and expressions relating to that word may be conveniently understood. In order to this, he distinguishes between *general* and *particular nature*.

NATURE, *general*, he defines the aggregate of the bodies which make up the world in its present state, considered as a principle by virtue whereof they act and suffer, according to the laws of motion prescribed by the Author of all things.

NATURE, *particular*, of any subordinate, or individual, consists in the general *nature* applied to a distinct portion of the universe. Or it is a convention of the mechanical properties (as magnitude, figure, order, situation, and local motion) of parts convenient and sufficient to constitute, or intitle to its particular species or denomination, the particular body they make up; the concourse of all these being considered as the principle of motion, rest, &c.

NATURE, *laws of*. See LAW.

NATURE, *laws of*, are axioms, or general rules, of motion, and rest, observed by natural bodies in their actions on one another; and in all the changes which befal them in their natural state.

The *laws of nature* and *of motion*, are, in effect, the same: custom, indeed, has made some difference; and we find authors call the particular cases of motion, laws of motion; which see under MOTION. The more general, and comprehensive ones, and those from which, as from axioms, the others are deduced, they call *laws of nature*.

Of these, Sir Isaac Newton has established three:

1. That every body perseveres in the same state, either of rest, or uniform rectilinear motion; except so far as it is forced to change that state by some foreign force.

Thus projectiles persevere in their motions, except so far as they are retarded by the resistance of the air, and gravity: and thus a top, whose parts, by their cohesion, are continually drawing one another out of their rectilinear motion, only ceases to run round because resisted by the air, and the friction of the plane on which it moves.

And thus the larger bodies of the planets and comets preserve their progressive and circular motions a long time undiminished, in regions void of all sensible resistance.

A body is passive in receiving its motion, and the direction of its motion, so it retains them or perseveres in them, without any change, till it be acted upon by something external. See *Vis insertia*, RESISTANCE, and MEDIUM.

2. The change of motion is ever proportional to the moving force whereby it is effected, and in the direction of the right line wherein that force is impressed.

If a certain force produce a certain motion, a double force will produce double the motion; a triple force triple the motion; whether it be impressed all at once, or successively, and by degrees. And this motion (since it is ever directed to the same point with the generating force), if the body were in motion before, is either to be added to it, as where the motions conspire; or subtracted from it, as where contrary; or added obliquely, as where oblique: and is compounded with it, according to the determinations of each.

3. Re-action is always contrary and equal to action; or the actions of two bodies upon one another are always mutually equal, and directed contrary ways: and are to be estimated always in the same right line.

Whatever presses or pulls another, is equally pressed or pulled thereby. Thus, if I press a stone with my finger, the finger is equally pressed by the stone: if a horse draw a weight by a rope, the horse is equally drawn back towards the weight: for the rope being equally stretched each way, will, with an equal endeavour to relax itself, drive the horse toward the stone, and the stone toward the horse; and will hinder the progress of the one, as much as it promotes that of the other.

Again, if any body, by striking on another, do in any manner change its motion, it will, itself, by means of the other, undergo also an equal change in its own motion, by reason of the equality of the pressure.

When two bodies meet, each endeavours to persevere in its state, and resist any change: and because the change which is produced in either may be equally measured by the action which it excites upon the other, or by the resistance which it meets with from it, it follows that the changes produced in the motions of each are equal, but are made in contrary directions. The one acquires no new force but what the other loses in the same direction; nor does this last lose any force but what the other acquires: and hence, though by their collisions, motion passes from the one to the other, yet the sum of their motions, estimated in a given direction, is preserved the same, and is unalterable by their mutual actions upon each other.

In these actions the changes are equal; not those, we mean, of the velocities, but those of the motions, the bodies being supposed free from any other impediments. For the changes of velocities, which are likewise made contrary ways, inasmuch as the motions are equally changed, are reciprocally proportional to the bodies.

This law also obtains in attractions. See ATTRACTION.

NATURE, in *Mythology*, is used by the poets sometimes for the mother, sometimes for the daughter, and at other times for the companion of Jupiter. She is described by the symbols of the DIANA of Ephesus.

NATURE, in *Prosody*. A syllable is said to be long or short by *nature*, to signify that it is so originally, and independently of any rule of grammar, which might render it so by position or otherwise.

NAVAGIUM, in our *Old Writers*, a duty incumbent on tenants to carry their lord's goods in a ship. *Lib. 9. fol. ab omne carragio, navagio, &c.*

NAVAL, something relating to SHIPS, or NAVIGATION. In this sense we sometimes say, *naval strength*, a *naval* combat, &c.

NAVAL *crown*, *corona navalis*, among the ancient Romans, a crown adorned with figures of prows of ships, conferred on persons who, in sea-engagements, first boarded the enemy's vessel.

Though A. Gellius seems to speak in the general, where he says the *naval crown* was adorned with prows of ships. Lipsius distinguishes two kinds of *naval crowns*; the one he calls *simple*, the other *restricted*.

The first he supposes plain, and given to the common soldiers, &c. The latter, much more glorious, adorned with prows of ships, and only given to generals, or admirals, who had gained some important victory at sea. See CROWN.

NAVAL *stores*, comprehend all those particulars made use of, not only in the royal navy, but in every other kind of navigation: as timber and iron for shipping, pitch, tar, hemp, cordage, sail-cloth, gun-powder, ordnance, and fire-arms of every sort, ship-chandlery wares, &c.

Persons stealing or embezzling any of the king's *naval stores* to the value of 20*s.* are guilty of felony, without benefit of clergy. 22 Car. II. cap. 5. And the treasurer and commissioners of the navy are impowered to inquire of *naval stores* embezzled, and appoint persons to search for them, &c. who may go on board ships, and seize such *stores*; and the commissioners, &c. may imprison the offenders, and fine them double value, the *stores* being under the value of 20*s.* 1 Geo. I. cap. 25.

None but the contractors with the commissioners of the navy, shall make any *stores* of war, *naval stores*, &c. with the marks commonly used to his majesty's *stores* upon

pain of forfeiting 200*l*. And persons in whose custody such stores shall be found concealed, are liable to the same penalty. 9 & 10 Will. III. cap. 41. There have been several statutes successively enacted for regulating the purchase and conveyance, and encouraging the importation of *naval* stores from America and North Britain; the recital of which is neither expedient nor necessary in this work. See *Art of* NAVIGATION.

NAVALIA, among the Romans, were docks or ports where ships used to be laid up after building.

NAVALIA likewise signified the wharfs or keys at Rome, where the ships used to load and unload their goods, all which were near the Sublician bridge.

NAUCLEA, in *Botany*, a genus of the *pentandria monogynia* class; the characters of which are, that the corolla is funnel-shaped; that it has a single bilocular seed; and that the common receptacle is globose. There is only one species.

NAUCRARI, Ναυκραροι, among the Athenians, a designation given to the chief magistrates of the δημοι, boroughs or townships, which were likewise called ναυκρατιαι, because each of them were obliged, besides two horsemen, to furnish out one ship for the public service.

NAVE, in *Architecture*, NAVIS *ecclesiæ*, denotes the body of a church; or the place where the people are seated, reaching from the rail, or baluster, of the choir, to the chief door.

Balus derives the word from the Greek νεως, *temple*; which Salmasius brings further from νεος, *ship*; by reason the vault or roof of a church bears resemblance to a ship. The ancient Greeks called the *nave*, *pronaos*; the Latins frequently called it *cella*.

The *nave* of the church belongs to the parishioners: it belongs to them to repair it, &c.

NAVE *of a wheel*, is that short thick piece in the centre of the wheel, which receives the end of the axle-tree, and in which the ends of the spokes are fixed; it is bound at each end with hoops of iron, called the *nave-bands*: it has likewise in each end of the hole, through which the end of the axle-tree goes, a ring of iron called the *box*, or *boxier*, which fixes the hole of the *nave* from wearing.

NAVE-*lines*, in *Sea-Language*, is a sort of small tackle, depending from the head of the main-mast and fore-mast, and fastened to the middle of the parrel, immediately behind the mast, and communicating with the gears. It is used to keep the parrel directly opposite to the yard, and particularly whilst hoisting or lowering, as it would otherwise hang under the yard, and prevent it from being sufficiently braced.

NAVEL, a part in the middle of the belly, by anatomists called UMBILICUS. See *Tab. Anat. (Splanch.) fig.* 3. *lit. c. fig.* 16. *lit. c.*

NAVEL-*string* by anatomists is called *funiculus* UMBILICALIS.

It is a method universally received by prudent surgeons and midwives, to make an exact ligature upon the umbilical cord or *navel-string* of the new-born infant, lest it should bleed to death through the vessels which compose it. This ligature is to be made, as soon as the infant and after-burthen are delivered, with a strong thread of about an ell long, folded together four times; and having made a knot at one end, it is then to be passed twice round the *navel-string*, at about two or three fingers breadth from the abdomen, and afterwards tied with a double knot: this done, the cord leading to the placenta may be divided with a pair of scissars below the ligature, and the wounded part belonging to the infant, dressed with lint, after which it may be left to the nurse till it becomes dry, and falls off of itself.

There have been instances of some children receiving no harm from cutting the *navel-string*, without the ceremony of the ligature; but as there have also been too many instances of their dying by the omission, and as the operation is so easy, the midwife is unpardonable who omits it. Heister.

Dr. Schulze contradicts the common opinion concerning the umbilical vessels: he endeavours to prove, that the *navel* is not formed by the ligature which the midwives make, or by animals gnawing the *navel-string* of their young with their teeth, but by nature; and that the umbilical vessels separate spontaneously, or with very little force, from the interior surface of the skin; after which the umbilical vessels within the young creature's body contract and shrivel, their extremity by which they adhered to the navel becoming black and pointed, as if they had been burnt, and at last disappearing altogether: for, says he, what are commonly described, as these vessels changed into ligaments, are no other than the sheaths in which they were formerly contained. From this doctrine he concludes, that it is unnecessary to make any ligature upon the *navel-string* after birth. In confirmation of this, Dr. Eller relates several instances of the *navel-string* of children being left untied after they were cut, without being attended with any haemorrhage, or other bad consequence. Commerc. Norimb. 1733. Hebd. 28. sect. 2.

Mr. Monro is of opinion, that the fœtus in viviparous animals receives its nutrition from the umbilical vessels alone. See FŒTUS.

It has been observed, that in blowing into the placenta by the umbilical vessels, the air and the blood were easily forced out of it, by that surface of the placenta which is affixed to the uterus; but that they could by no means be driven out at the other surface which is towards the fœtus. Hence it is to be observed, that the uterus appears not to be covered by any membrane within, and that the placenta also has none on that side where it adheres to the womb, so that there is nothing to prevent the blood from readily flowing from the uterus into the placenta, and thence to the child. What we usually understand by the word membrane is a covering of so close a texture, as to keep out air, or fluids; and it is very evident to reason, that the placenta ought to have no such on that part where it is to communicate with the uterus; neither can the eye discover any such there, though on the other side it is easy to distinguish one.

The *navel-string*, beside its vein, and its two arteries, is composed of a spongy substance, in which these vessels are lodged; this spongy substance is composed of a number of cellules which communicate with one another, and contain a glutinous liquor, which is usually found in them in great abundance: if we consider the *navel-string* as a cylinder, the blood-vessels run in a spiral round its axis, and are laid one over another, but that differently in different subjects; hence it is that the *navel-string* is tortuous.

When the vessels have run through the whole length of the *navel-string*, in the same diameter, they break into a number of branches, and enter the placenta, where they afterwards divide themselves into capillary ramifications. The diameter of the vein is all the way double to that of both the arteries; so that it contains twice as much blood as the two arteries together. If the *navel-string* were only composed of these three vessels, the fœtus, in moving, might easily compress them in such manner, as to stop the current of the blood, and its inevitable death must be the consequence of this; but nature having provided this spongy, or cellular substance, for their lodgement, this is able to give way to them, when pressed in any direction, and enables them, therefore, to bear a considerable force, without the current of the blood being stopped by them in it; nor is the glutinous liquor, of which those cells are full, of little use in lubricating these vessels. Mem. Acad. Par. 1724.

NAVEL-*boods*, in *Ship-Building*, large pieces of stuff fitted into the hawse-holes, to keep the cables from wearing them.

NAVEL-*wort*, *cotyledon*, in *Botony*, a genus of the *decandria pentagynia* class. Its characters are these: the flower, which hath a small empalement of one leaf, divided into five parts at the top, has one petal, which is funnel-shaped, cut into five parts at the brim; and five germina, which have each a squamous concave nectarium at the base, and ten erect stamina; the germina afterwards become so many oblong swelling capsules, opening longitudinally with one valve, and filled with small seeds. Miller enumerates ten, and Linnæus eight species.

The *cotyledons*, when not in flower, may usually be known by having thick, tuberose roots, and thick or fatty roundish leaves. These, however, are found to be no certain characters, as there are plants truly of this genus, which have long leaves, and fibrose roots.

The greater *navel-wort*, with hooded leaves, sharply indented and growing alternate, and a branching stalk, with erect flowers, used in medicine, grows upon old walls and buildings, in many parts of England, particularly in Shropshire and Somersetshire, and is reckoned gently cooling and moistening, refrigerating and astringent; useful in hot distempers of the liver: it provokes urine, and takes off the heat and sharpness of it. The juice of it outwardly applied, helps the shingles, St. Anthony's fire, the pain and inflammation of the piles; and is useful against kibes and chilblains: it is an ingredient in the *unguentum pæpileon*.

NAVEL-*wort*, *bastard*. See CRASSULA.

NAVEL-*wort*, *Venus's*, the name of a genus of plants, called by authors, *umbilicus*. See HOUND'S *Tongue*.

NAVEL-*wort*, *water*, a name sometimes given to the *hydrocotyle* of botanists. See *Marsh* PENNY-*wort*.

NAVETTE, the name by which most of the European nations call the *napus*, or *bunias sylvestris* of Lobel, the plant from the seeds of which the oil which we call rape oil, and the French and others *navette* oil, is expressed. The plant is cultivated in many parts of England, and in

other countries, for the sake of the seed; the oil drawn from this is used by many artificers, and is of a fine yellow colour, and the smell is not offensive. The cake, remaining after the expression of the oil, retains, like that of mustard, the acrimony of the seeds.

NAVEW, in *Botany*. See NAPUS.

NAVICULA, in *Natural History*, a name given by a late French author to the class of shells called by us the *nautili*. See NAUTILUS.

NAVICULARE *os*, in *Anatomy*, the third bone in the foot, between the astragalus, and the ossa cuneiformia. It is thus called from *navis*, *a ship*, to which it bears some resemblance; for which reason, likewise, it is sometimes called *cymbiforme*, from *cymba*, *a boat*; and *schaphoides*, from a Greek word of the like import.

The *os naviculare* has behind it a large sinus, which receives the anterior convex head of the first bone; and before it is convex. It is divided into three heads, which are received into the sinuses of the ossa cuneiformia.

NAVIGATION, the art or act of sailing, or of conducting a vessel from one place to another, in the safest, shortest, and most commodious way.

This art, in the full latitude of the word, comprehends three parts: 1. The art of constructing and building ships. 2. The loading of ships. And, 3. The conducting and guiding of ships through the sea; which is, in a peculiar sense, called *navigation*, or SAILING.

In this restrained sense of the word, *navigation*, is either *common*, or *proper*.

NAVIGATION, *common*, usually called COASTING, is where the ports are on the same, or very neighbouring coasts; and where the vessel is seldom out of sight of land, or out of reach of sounding.

In this, little else is required but an acquaintance with the lands, the compass, and sounding-line; each of which see in its place, COMPASS, and SOUNDING.

NAVIGATION, *proper*, is where the voyage is long, and pursued through the main ocean.

In this, besides the requisites in the former, are likewise required use of the Mercator's chart, azimuth, and amplitude compasses, log-line, and other instruments for celestial observations; as quadrants, forestaffs, &c. See each instrument, &c. in its place.

Navigation turns principally on four things; two whereof being known, the rest are easily found from them by the tables, scales, and charts.

These four things are, the difference of latitude, difference of longitude, the reckoning or distance run, and the course or rhumb sailed on.

The latitudes are easily found, and that with sufficient accuracy. See LATITUDE.

The course and distance are had by the log-line, or dead reckoning, and the compass. See LOG, COMPASS, COURSE, and DISTANCE.

Nor is there any thing wanting to the perfection of *navigation*, but to determine the longitude. The mathematicians of many ages have applied themselves, with the utmost assiduity, to supply this grand desideratum, but not with the success that was desireable, considering the importance of the object, and the magnificent rewards of several princes and states to the discoverer.

For the various methods that now occasionally obtain at sea, for this purpose, and an account of the discoveries that have been made, see LONGITUDE.

The poets refer the invention of the art of *navigation* to Neptune, some of the ancients to Bacchus, others to Hercules, others to Jason, others to Janus, who is said to have made the first ship. Historians ascribe it to the Æginetes, the Phœnicians, Tyrians, and the ancient inhabitants of Britain. Some will have it, the first hint was taken from the flight of the kite; others, as Oppian de Piscibus, lib. i. from the fish called nautilus: others ascribe it to accident.

Scripture refers the origin of so useful an invention to God himself, who gave the first specimen thereof in the ark built by Noah. For the raillery the good man underwent on account of his enterprize, shews, evidently enough, the world was then ignorant of any thing like *navigation*; and that they even thought it impossible.

However, history represents the Phœnicians, especially those of their capital, Tyre, as the first *navigators*; being urged to seek a foreign commerce by the narrowness and poverty of a strip of ground they possessed along the coasts; as well as by the conveniency of two or three good ports; and by their natural genius for traffic.

Accordingly, Lebanon, and the other neighbouring mountains, furnishing them with excellent wood for ship-building, in a short time they were masters of a numerous fleet; with which constantly hazarding new *navigations*, and settling new trades, they soon arrived at an incredible pitch of opulency and populousness; having rendered themselves masters of several commodious harbours toward the bottom of the Arabian gulph, and, after the example of the Egyptians, established a regular intercourse with Arabia and the continent of India on the one hand, and with the eastern coast of Africa on the other: so that they were in a condition to send out colonies, the principal of which was that of Carthage; which, keeping up their Phœnician spirit of commerce, in time not only equalled Tyre itself, but vastly surpassed it; pursuing the course which the Phœnicians had opened, and sending its merchant-fleets through Hercules's Pillars, now the Streights of Gibraltar, along the western coast of Africa, to the south, almost to the tropic of Cancer, having discovered the Fortunate Islands, now known by the name of the Canaries, which were the utmost boundary of ancient *navigation* in the western ocean; and to the north along the coast of Europe, visiting particularly, Spain, Gaul, and Britain: and even, if we believe some authors, to America itself; the discovery whereof, so many ages afterwards, has been so glorious to the Spaniards.

The progress of the Phœnicians and Carthaginians was not owing merely to the desire of extending their trade from one country to another: voyages were undertaken, the sole object of which was to discover new countries, and to explore unknown seas. Such, during the prosperous age of the Carthaginian republic, were the famous *navigations* of Hanno and Himilco. Both their fleets were equipped by authority of the senate, and at the public expence. Hanno was directed to steer towards the south, along the coast of Africa, and he seems to have advanced much nearer the equinoctial line than any former navigator. Himilco had it in charge to proceed towards the the north, and to examine the western coasts of the European continent. Of the same nature was the extraordinary *navigation* of the Phœnicians round Africa. A Phœnician fleet, we are told (Herod. lib. iv. cap. 42.) fitted out by Necho, king of Egypt, took its departure, about 604 years before the Christian æra, from a port in the Red Sea, doubled the southern promontory of Africa, and after a voyage of three years, returned by the streights Gades, to the mouth of the Nile. Eudoxus of Cyzicus, is said (Plin. Nat. Hist. lib. ii. cap. 67.) to have held the same course, and to have accomplished the same arduous undertaking. However, long after this *navigation* of the Phœnicians and of Eudoxus round Africa, Polybius, the most intelligent and best informed historian of antiquity, affirms, that it was not known, in his time, whether Africa was a continued continent, stretching to the south, or whether it was encompassed by the sea. Polyb. Hist. lib. iii. And it appears from the testimony of Pliny, (Hist. Nat. lib. ii. cap. 68.) Strabo, (lib. ii. p. 155. lib. xvii. p. 1180) Ptolemy (Geogr. lib. iv. cap. 9.) that the accounts of those voyages were not fully credited. Robertson's Hist. America, vol. i. p. 13. p. 354. ed. 8vo.

Tyre, whose immense riches and power are represented in such lofty terms, both in sacred and profane authors, being destroyed by Alexander the Great, its *navigation* and commerce were transferred by the conqueror to Alexandria, a new city, admirably situated for those purposes, proposed for the capital of the empire of Asia, which Alexander then meditated. And thus arose the *navigation* of the Egyptians, which was afterwards so cultivated by the Ptolemies, that Tyre and Carthage (which last, after having a long time disputed empire with the Romans, was at length subdued) were quite forgot.

Egypt being reduced into a Roman province after the battle of Actium, its trade and *navigation* fell into the hands of Augustus; in whose time Alexandria was only inferior to Rome: and the magazines of the capital of the world were wholly supplied with merchandizes from the capital of Egypt.

At length, Alexandria itself underwent the fate of Tyre and Carthage, being surprised by the Saracens; who, in spite of the emperor Heraclius, overspread the northern coasts of Africa, &c. whence the merchants being driven, Alexandria has ever since been in a languishing state, though still it enjoys a considerable part of the commerce of the Christian merchants, trading to the Levant.

The fall of Rome, and its empire, drew along with it not only that of learning, and the polite arts, but that of *navigation*; the Barbarians, into whose hands it fell, contented themselves with the spoils of the industry of their predecessors.

However, one circumstance prevented commercial intercourse with distant nations from ceasing altogether. Constantinople, though often threatened by the fierce invaders, who spread desolation over the rest of Europe, was so fortunate as to escape their destructive rage. In that city, the knowledge of ancient arts and discoveries was preserved; and commerce continued to flourish there, with the taste for elegance, and the luxuries of foreign countries, when it was almost extinct in every other part of Europe. The citizens of Constantinople did not confine their trade to the islands of the Archipelago, or to the adjacent coasts of Asia: they took a

wider

wider range, and following the courſe which the ancients had marked out, imported the commodities of the Eaſt Indies from Alexandria. When Egypt was torn from the Roman empire by the Arabians, the induſtry of the Greeks diſcovered a new channel, by which the productions of India might be conveyed to Conſtantinople. They were carried up the Indus, as far as that great river is navigable; there they were tranſported by land to the banks of the river Oxus, and proceeded down its ſtream to the Caſpian ſea. There they entered the Volga, and ſailing up it, were carried by land to the Tanais, which conducted them into the Euxine ſea, where veſſels from Conſtantinople waited their arrival.

But no ſooner were the more brave among thoſe nations well ſettled in their new provinces, ſome in Gaul, as the Franks; others in Spain, as the Goths; and others in Italy, as the Lombards; but they began to learn the advantages of *navigation* and commerce, and the proper methods of managing them, from the people they ſubdued; and this with ſo much ſucceſs, that in a little time ſome of them became able to give new leſſons, and ſet on foot new inſtitutions, for its advantage.

Thus it is to the Lombards we uſually aſcribe the invention and uſe of banks, book-keeping, exchanges, rechanges, &c.

It does not appear which of the European people, after the ſettlement of their new maſters, firſt betook themſelves to *navigation* and commerce. Some think, it began with the French; though the Italians ſeem to have the juſteſt title to it, and are accordingly ordinarily looked on as the reſtorers hereof; as well as the polite arts, which had been baniſhed together, from the time the empire was torn aſunder.

The people of Italy, then, and particularly thoſe of Venice and Genoa, have the glory of this reſtoration; and it is to their advantageous ſituation for *navigation*, they in a great meaſure owe their glory.

In the bottom of the Adriatic were a great number of marſhy iſlands, only ſeparated by narrow channels, but thoſe well fenced, and almoſt inacceſſible, the reſidence of ſome fiſhermen, who here ſupported themſelves by a little trade of ſalt and ſalt, which they found in ſome of theſe iſlands. Thither, then, the Veneti, a people inhabiting that part of Italy along the coaſts of the gulph, retired, when Alaric, king of the Goths, and afterwards Attila, king of the Huns, ravaged Italy.

Theſe new iſlanders, little imagining that this was to be their fixed reſidence, did not think of compoſing any body politic; but each of the ſeventy-two iſlands of this little Archipelago continued a long time under its ſeveral diſtinct maſters, and each made a diſtinct commonwealth. When their commerce was become conſiderable enough to give jealouſy to their neighbours, they began to think of uniting into a body: and it was this union, firſt begun in the ſixth century, but not completed till the eighth, that laid the ſure foundation of the future grandeur of the ſtate of Venice.

From the time of this union, their fleets of merchantmen were ſent to all the parts of the Mediterranean; and at laſt to thoſe of Egypt, particularly Cairo, a new city, built by the Saracen princes on the eaſtern bank of the Nile, where they traded for their ſpices, and other productions of the Indies.

Thus they flouriſhed, increaſed their commerce, their *navigation*, and their conqueſts on the terra firma, till the famous league of Cambray, in 1508, when a number of jealous princes conſpired to their ruin; which was the more eaſily effected, by the diminution of their Eaſt India commerce, of which the Portugueſe had got one part, and the French another.

Genoa, which had applied itſelf to *navigation* at the ſame time with Venice, and that with equal ſucceſs, was a long time its dangerous rival, diſputed with it the empire of the ſea, and ſhared with it the trade of Egypt, and other parts both of the Eaſt and Weſt.

Jealouſy ſoon began to break out; and the two republics coming to blows, it was three centuries almoſt continual war, before the ſuperiority was aſcertained; when, towards the end of the fourteenth century, the fatal battle of Chiona ended the noble ſtrife; the Genoeſe, who till then had uſually the advantage, having now loſt all: and the Venetians, almoſt become deſperate, at one happy blow, beyond all expectation, ſecured to themſelves the empire of the ſea, and ſuperiority in commerce.

The CRUSADES contributed in a great meaſure to the revival, or at leaſt to the more rapid progreſs of commerce and *navigation*; for the Genoeſe, the Piſans, and Venetians, furniſhed the tranſports, which carried thoſe vaſt armies, compoſed of all the nations in Europe, into Aſia, upon this wild enterprize; and likewiſe ſupplied them with proviſions and military ſtores.

Other travellers, beſides thoſe whom religious zeal ſent forth to viſit Aſia, ventured into remote countries, from the proſpect of commercial advantage, or from motives of mere curioſity. The firſt and moſt eminent of theſe was Marco Polo, a Venetian of a noble family, about the year 1269: he was ſucceeded about half a century after by Sir John Mandeville, an Engliſhman. But the preſent art of *navigation* owed its riſe to the invention of the mariner's COMPASS, in the beginning of the fourteenth century; and made conſiderable progreſs during the voyages that were begun in the year 1418, by Henry, duke of Viſeo. This learned prince, brother to Edward, king of Portugal, was particularly ſkilled in coſmography, and employed a perſon from the iſland of Majorca, to teach navigation, and to make inſtruments and charts for the ſea. Theſe voyages, being greatly extended after the diſcovery of Porto Santo and Madeira, the art was improved under the ſucceeding monarchs of that nation: eſpecially that Roderic and Joſeph, phyſicians to king John II. together with one Martin de Bohemia, a Portugueſe native of the iſland of Fayal, ſcholar to Regiomontanus, about the year 1485, calculated for the uſe of the ſailors tables of the ſun's declination, and recommended the aſtrolabe, for taking obſervations at ſea. About this time, Columbus, a native of Genoa, having thoroughly acquainted himſelf with the diſcoveries and obſervations of the Portugueſe, and having alſo acquired conſiderable experience in the art of *navigation*, made a propoſal to king John II. of exploring a paſſage to India, by ſailing directly towards the weſt, across the Atlantic ocean. John rejected this propoſal in a very diſhonourable manner: and Columbus inſtantly quitted the kingdom, and landing in Spain towards the cloſe of the year 1484, he reſolved to propoſe his plan to Ferdinand and Iſabella, with whom, after repeated application and long delay, he ultimately ſucceeded. In Auguſt, 1492, Columbus, furniſhed with a ſmall armament of three ſhips, ſet ſail, and ſteered directly for the Canary iſlands; from thence holding his courſe due weſt, he ſtretched away into unfrequented and unknown ſeas. After many difficulties, he at length arrived at Guanahani, one of the large cluſter of iſlands, called the Lucaya, or Bahama iſles. He alſo diſcovered Cuba, Hiſpaniola, and ſeveral other ſmall iſlands, and having left a ſmall colony in a fort at Hiſpaniola, returned to Spain, in March, 1493. In September following, he ſet out on his ſecond voyage, and ſailed by the Leeward iſlands to Hiſpaniola: in a third voyage, undertaken in the year 1498, he diſcovered the continent of America. In the ſame year, Vaſco de Gama returned to Liſbon, from a voyage to the Eaſt Indies by the Cape of Good Hope. Columbus, it is ſaid, before he attempted the diſcovery of America, conſulted Martin de Bohemia, as well as others, and during the courſe of his voyage, inſtructed the Spaniards in *navigation*; for the improvement of which art, the emperor Charles V. afterwards founded a lecture at Seville. This art was conſiderably improved by the diſcovery of the VARIATION of the compaſs, and by the uſe of the CROSS-*ſtaff*. At length there were publiſhed in Spaniſh, two treatiſes, containing a ſyſtem of the art, which were in great eſteem: the firſt by Pedro de Medina, at Valladolid, in 1545, called Arte de Navegar; the other at Seville, in 1556, by Martin Cortes, under the title of Breve Compendio de la Sphera, y de la Arte de Navegar, con nuevos Inſtrumentos y Reglas. This is ſaid to have been compoſed at Cadiz, in 1545; and a tranſlation of it was publiſhed in London, in 1561, which paſſed through ſeveral impreſſions. Beſides the improvement which the art of *navigation* received from the propoſals of Werner, and Gemma Friſius, for finding the LONGITUDE, it was much promoted by Pedro Nunez, or Nonius, who compoſed a treatiſe on this ſubject, ſo early as 1537, in the Portugueſe language, which thirty years after was printed at Baſil in Latin, with additions, under the title of De Arte et Ratione Navigandi. In this work, the errors of the plane chart are expoſed, and the problem of determining the latitude, from two obſervations of the ſun's altitude, and the intermediate azimuth, is reſolved. In 1577, Mr. William Bourne publiſhed his treatiſe, intitled A Regiment for the Sea, and intended as a ſupplement to that of Cortes. See LOG.

The miſtakes of Medina were well expoſed by Michael Coignet, a native of Antwerp, who, in 1581, publiſhed a ſmall treatiſe intitled, Inſtruction Nouvelle des Points plus excellents and neceſſaires touchant l'Art de Naviger. In the ſame year Mr. Robert Norman publiſhed his diſcovery of the DIPPING-*needle*, in a pamphlet called the New Attractive; to which is always ſubjoined Mr. William Burrough's Diſcourſe of the Variation of the Compaſs. In 1594, Captain John Davis publiſhed a ſmall treatiſe, intitled the Seaman's Secrete, which was much eſteemed in its time. The writers of this period com-

complained much of the errors of the plane chart, which continued ſtill in uſe, though they were unable to diſcover a proper remedy: ſtill Gerrard Mercator contrived his univerſal map, (ſee *Mercator's* CHART) which he publiſhed in 1569, without clearly underſtanding the principles of its conſtruction: theſe were firſt diſcovered by Mr. Edward Wright, who ſent an account of the true method of dividing the meridian from Cambridge, where he was a fellow, to Mr. Blundeville, with a ſhort table for that purpoſe, and a ſpecimen of a chart ſo divided. Theſe were publiſhed by Blundeville in 1594, among his Exerciſes; to the later editions of which was added his diſcourſe of Univerſal Maps, firſt printed in 1589. However, in 1599, Mr. Wright printed his Correction of certain Errors in *Navigation*, in which work he ſhews the reaſon of this diviſion, the manner of conſtructing his table, and its uſes in *navigation*. A ſecond edition of this treatiſe, with farther improvements, was printed in 1610, and a third edition by Mr. Moxon, in 1657. The method of approximation, by what is called the middle latitude, now uſed by our ſailors, occurs in Gunter's Works, firſt printed in 1623. About this time LOGARITHMS began to be introduced, which were applied to *navigation* in a variety of ways by Mr. Edmund Gunter; though the firſt author who applied the logarithmic tables to the caſes of ſailing, was Mr. Thomas Addiſon, in his Arithmetical *Navigation*, printed in 1625. In 1633 Mr. Henry Gellibrand printed a Diſcourſe Mathematical on the Variation of the Magnetical Needle, containing his diſcovery of the changes to which the VARIATION is ſubject. In 1631 Mr. Richard Norwood publiſhed an excellent Treatiſe of Trigonometry, adapted to the invention of logarithms, particularly in applying Napier's general canons; and for the farther improvement of *navigation*, he undertook the laborious work of meaſuring a DEGREE of the meridian, for examining the diviſions of the *Log-line*. Of this affair he has given a full and clear account in his Seaman's Practice, firſt publiſhed in 1637; where he alſo deſcribes his own excellent method of letting down and perfecting a ſea-reckoning, &c. This treatiſe, and that of trigonometry, were continually reprinted, as the principal books for learning ſcientifically the art of *navigation*. What he had delivered, eſpecially in the latter of them, concerning this ſubject, was contracted as a manual for ſailors in a very ſmall piece, called his Epitome, which has gone through innumerable editions. About the year 1645, Mr. Bond publiſhed, in Norwood's Epitome, a very great improvement in Wright's method, by a property in his meridian line, whereby its diviſions are more ſcientifically aſſigned than the author himſelf was able to effect; which he deduced from this theorem, that theſe diviſions are analogous to the exceſſes of the logarithmic tangents of half the reſpective latitudes augmented by forty-five degrees above the logarithm of the radius: this he afterwards explained more fully in the third edition of Gunter's Works, printed in 1653; and the demonſtration of the general theorem was ſupplied by Mr. James Gregory of Aberdeen, in his Exercitationes Geometricæ, printed at London in 1668, and afterwards by Dr. Halley, in Phil. Tranſ. N° 219, and by Mr. Cotes, Phil. Tranſ. N° 388. In 1700, Mr. Bond, who imagined that he had diſcovered the longitude, by having found out the true theory of the magnetic variation, publiſhed a general map, on which were delineated curve lines, expreſſing the paths where the magnetic needle had the ſame variation. The poſitions of theſe curves will indeed continually ſuffer alterations; but they ſhould be corrected from time to time, as they have already been for the years 1744 and 1756, by Mr. William Mountaine, and Mr. James Dodſon. The allowances proper to be made for LEE way are very particularly ſet down by Mr. John Buckler, and publiſhed in a ſmall tract firſt printed in 1702, intitled, a New Compendium of the whole Art of *Navigation*, written by Mr. William Jones.

As it is now generally agreed that the earth is a ſpheroid, whoſe diameter at the poles is ſhorter than the other, Dr. Murdoch publiſhed a tract in 1721, wherein he accommodated Wright's ſailing to ſuch a figure; and Mr. Maclaurin in the ſame year gave a rule, in the Phil. Tranſ. N° 361, for determining the meridional parts of a ſpheroid, which ſpeculation he has farther proſecuted in his Fluxions, printed at Edinburgh in 1742.

The principal foreign writers on *navigation* are Bartholomew Creſcenti, of Rome, in 1607; father George Fournier, at Paris, in 1633; John Baptiſt Riccioli, at Bologna, in 1661; father Millet Dechales, in 1674 and 1677; the ſieur Blondel de Auhin, in 1671 and 1673; M. Deſnier, in 1683; M. Sauveur, in 1692; M. John Bouguer, in 1698; father Peranas, in 1733 and 1741; and M. Peter Bouguer, who, in 1753, publiſhed a very elaborate treatiſe on this ſubject, intitled, Nouveau Traité de Navigation; in which he gives a variation-compaſs of his own invention, and attempts to reform the LOG, as he had done in the Memoirs of the Academy of Sciences for 1747. He is alſo very particular in determining the lunations more accurately than by the common methods, and in deſcribing the corrections of the dead reckonings. This book was abridged and improved by M. de la Caille, in 1760: to theſe we may add Don George Juan of Spain, in 1757. For an account of the ſeveral ſteps that have been purſued for the diſcovery of the longitude, ſee LONGITUDE. For an account of Hadley's quadrant, and its uſe in nautical obſervations, ſee QUADRANT. For the method of making artificial magnets, and their uſe, ſee MAGNET, COMPASS, and NEEDLE.

Thoſe who are deſirous of peruſing a fuller account of the progreſs of *navigation*, may conſult Dr. James Wilſon's preface to Dr. Robertſon's Elements of *Navigation*, in two volumes, octavo, 1732; a work deſervedly held in the higheſt eſtimation.

But to return to the hiſtory of *navigation* in its connection with commerce. About the ſame time that *navigation* was retrieved in the ſouthern parts of Europe, a new ſociety of merchants was formed in the North; which not only carried commerce to the greateſt perfection it was capable of, till the diſcovery of the Eaſt and Weſt Indies, but alſo formed a new ſcheme of laws for the regulation thereof, which ſtill obtain, under the name of *Uſes and cuſtoms of the ſea*.

This ſociety is that famous league of the HANSE-*towns*, commonly ſuppoſed to have begun about the year 1164.

For the modern ſtate of *navigation* in England, Holland, France, Spain, Portugal, &c. ſee COMMERCE, COMPANY, &c.

We ſhall only add, that, in examining the reaſons of commerce's paſſing ſucceſſively from the Venetians, Genoeſe, and Hans-towns, to the Portugueſe and Spaniards, and from thoſe again to the Engliſh and Dutch, it may be eſtabliſhed as a maxim, that the relation between commerce and *navigation*, or, if we may be allowed to ſay it, their union, is ſo intimate, that the fall of the one inevitably draws after it the other; and that they will always either flourith or decline together.

Hence ſo many laws, ordinances, ſtatutes, &c. for its regulation; and hence, particularly, that celebrated act of *navigation*, which an eminent foreign author calls the Palladium, or tutelar deity, of the commerce of England; which is too important not to be here mentioned; as it is the ſtanding rule, not only of the Engliſh among themſelves, but alſo of other nations with whom they traffic.

NAVIGATION, *act of Engliſh*, is a ſtatute whereby the parliament of England have ſettled divers matters relating to the *navigation* and commerce of this kingdom.

Till this act, all nations were at liberty to import into England all kinds of merchandizes, whether of their own growth, or laden elſewhere, and that on board their own veſſels.

For, though by the ſtatute 5 Ric. II. cap. 3. for augmenting the navy of England, then greatly diminiſhed, it was ordained, that none of the king's liege people ſhould ſhip any merchandize out of or into the realm, but only in ſhips of the king's ligeance, on pain of forfeiture; yet in the next year, by 6 Ric. II. cap. 8. this wiſe proviſion was enervated, by only obliging the merchants to give Engliſh ſhips (if able and ſufficient) the preference. And though by 4 Hen. VII. cap. 10. it was enacted, that no Gaſcoign or Guienne wines, &c. ſhould be imported into this realm, except in Engliſh veſſels, and that none ſhould freight any merchandize in any ſtranger's ſhip, if he could have ſufficient freight in a denizen's ſhip, under the penalty of forfeiting all merchandize not thus ſhipped, to be divided between the king and the ſeizer; yet this act, ſo far as it related to the above wines, was repealed by the ſtatute 32 Hen. VIII. cap. 14. and a rate was ordered of what ſhould be paid for the freight of the ſeveral ſorts of merchandize in ſhips, from the port of London to other places, and from thence to London. By 1 Eliz. cap. 13. it was enacted, that if the owner of any merchandize ſhould, in the time of peace, embark or unload any part thereof (malts, pitch, tar, and corn, only excepted) out of, or into any foreign ſhip, he ſhould pay cuſtom as an alien. Cromwell, firſt, perceiving the prejudice the liberty above mentioned did to the Engliſh commerce, which was now almoſt wholly in the hands of foreigners, chiefly the Dutch, whom he hated, animated the Engliſh, by ſeveral acts of parliament, to retrieve their trade into their own hands; and, particularly, paſſed an act, prohibiting the Dutch from importing any merchandizes, except thoſe of their own growth, or manufacture, which were very few.

This act, framed in 1650, and intended to mortify the ſugar iſlands, which were diſaffected to the parliament, and

and held out for Charles II. forbid all ships of foreign nations from trading with any Engliſh plantations, without licence from the council of ſtate. In 1651 the prohibition was extended alſo to the mother-country; and no goods were ſuffered to be imported into England, or any of its dependencies, in any other than Engliſh bottoms; or in the ſhips of that European nation of which the merchandize imported was the genuine growth or manufacture.

Upon the Reſtoration, the firſt parliament Charles II. called, diſtinguiſhing in Cromwell the politician from the uſurper, condemned the memory of the one, and followed the plan of the other with regard to *navigation* and commerce, by paſſing that celebrated bill, or act, for the encouraging and increaſing of ſhipping, and of *navigation*, which ſtill ſubſiſts in its full latitude, and in ancient rigour. Its date is from the firſt of December, 1660, 12 Car. II. cap. 18. Its chief articles follow.

1. That no goods or commodities ſhall be imported or exported to or from any of the Engliſh colonies in Aſia, Africa, or America, but on veſſels built within the dominions of England, or really belonging to Engliſhmen, and whoſe maſters, and at leaſt three-fourths of the crew, are Engliſh, on pain of forfeiture of the goods and veſſel.

Under the name *Engliſh* here, are comprehended all the king's ſubjects of England, Ireland, and the plantations; as was explained in a ſubſequent act, 13 & 14 Car. II. cap. 11.

2. That no perſon born out of the ſubjection of England, or not naturaliſed, ſhall exerciſe any commerce in thoſe colonies for himſelf, or others.

3. That no merchandizes of the growth of Aſia or America ſhall be imported into any of the dominions of England, on any other than Engliſh veſſels.

4. That no goods of foreign growth or manufacture that ſhall be brought into England, Wales, Ireland, iſlands of Jerſey or Guernſey, or town of Berwick on Tweed, in Engliſh-built ſhipping, or other ſhipping belonging to the foreſaid places, and *navigated* by Engliſh mariners, as aforeſaid, ſhall be ſhipped or brought from any other place or country, but only from thoſe of the growth or manufacture thereof.

5. That all kinds of dried and ſalted ſea-fiſh, train-oils, blubber, and whale-fins, not caught by Engliſh veſſels, imported into England, ſhall pay double duties.

6. That the commerce from port to port in England and Ireland ſhall be carried on wholly by Engliſh veſſels, and Engliſh merchants; the crew to be always three-fourths Engliſh.

7. That none but Engliſh veſſels ſhall reap the benefit of the diminutions made, or abatements to be henceforth made, in the cuſtoms.

8. All veſſels are prohibited importing into England and Ireland any of the commodities of Muſcovy, or even any maſts, or other timber, foreign ſalt, pitch, reſin, hemp, raiſins, prunes, oil of olive, any kind of corn or grain, ſugars, aſhes, and ſoap, wine, vinegar, or brandy, except veſſels whereof Engliſh are owners or part-owners, and where the maſter and three-fourths of the mariners are Engliſh. And that no currans, or other commodities, the growth or manufacture of the Turkiſh empire, ſhall be imported, but in veſſels of Engliſh build, and *navigated* as aforeſaid; except only ſuch veſſels as are of the build of the country or place whereof ſuch commodities are the growth or manufacture, or of ſuch port where ſuch goods are uſually ſhipped for tranſportation, and unleſs the maſter and three-fourths of the crew be natives of the country where they are laden.

9. All timber, maſts, boards, ſalt, pitch, tar, reſin, hemp, flax, raiſins, figs, prunes, olive-oils, corn or grain, of any kind, ſugar, pot-aſhes, brandies and wines, and all goods of the growth and manufacture of Muſcovy, all currans and Turkiſh goods imported into England, &c. in other than ſuch ſhipping, and ſo navigated, ſhall be deemed aliens goods, and ſhall pay accordingly.

10. That, to prevent frauds in buying and diſguiſing foreign veſſels, the proprietors ſhall take an oath, that they really belong to them, and that no alien has any part in them.

11. That Engliſh veſſels, and *navigated* by Engliſh, may import into the dominions of England any merchandizes of the Levant, though not taken up in the places where they grow, or are manufactured; provided it be in ſome part of the Mediterranean beyond the Streights of Gibraltar. And the ſame in underſtood of commodities brought from the Eaſt Indies, provided they be taken up in ſome port beyond the Cape of Good Hope; and thoſe from the Canaries, and other colonies of Spain; and the Azores, and other colonies of Portugal; which are allowed to be ſhipped, the one in Spaniſh ports, the other in Portugueſe.

12. Theſe penalties, prohibitions, and confiſcations, not to extend to goods taken, by way of reprizal, from the enemies of England; nor to fiſh caught by the Scots, or their corn, and ſalt, which may be imported into England by the Scotch-built ſhips.

13. Five ſhillings per ton duty is impoſed on every French veſſel arriving in any port of England, ſo long (and even three months longer) as fifty ſols per ton lies on the Engliſh veſſels in France.

Laſtly, That ſugars, tobacco, and other commodities of the growth of the Engliſh colonies, ſhall not be imported into any other part of Europe, but the dominions of England; and that veſſels going out of the ports of the ſame crown for the Engliſh colonies, ſhall give 1000*l.* ſecurity, if under one hundred tons, and 2000*l.* if above, before they depart, that they will import their cargo into ſome port in the ſaid dominions; and the like, before they quit thoſe colonies, that they will land their whole cargo in England.

The 22 & 23 Car. II. cap. 11. alſo ordains, that where any goods ſhall be laden on board any Engliſh ſhip of the burden of two hundred tons, or upwards, and mounted with ſixteen guns, or more, if the maſter yields up ſuch ſhip or goods to any Turkiſh veſſel, or any pirate, without fighting, upon proof thereof in the admiralty, he ſhall be incapable of taking charge of any Engliſh veſſel; and maſters of Engliſh ſhips, though not of that burden, nor mounted as aforeſaid, that ſhall yield without fighting to a Turkiſh ſhip or pirate, that has not at leaſt double the number of guns, ſhall be liable to the penalties of this act. If any inferior officers or mariners of a ſhip, ſhall refuſe to fight when commanded, or utter words to diſcourage others, they ſhall loſe all their wages due, and be impriſoned not exceeding ſix months; and mariners laying violent hands on their commanders, to hinder them from fighting in defence of their ſhips, ſhall ſuffer death as felons. When any Engliſh ſhip ſhall have been defended by fight, and brought to her port, in which fighting any of her men have been wounded or ſlain, the judge of the admiralty, or his ſurrogate, &c. where the ſhall arrive, upon the petition of the maſter and ſeamen, may call ſo many as he ſhall be informed are the adventurers and owners, and by adviſing with them, levy upon the reſpective owners ſuch ſums as he himſelf, and the major part of them preſent, ſhall judge reaſonable, not exceeding two *per cent.* of the ſhip and goods; which money ſhall be diſtributed among the maſter, officers, and ſeamen, or the widows and children of the ſlain, according to the direction of the judge, with the approbation of three or more of the adventurers.

By the 5th and 6th of William and Mary, cap. 24. every perſon who ſhall build, or cauſe to be built, any ſhip of three decks, containing 450 tons, and mounted with thirty-two pieces of ordnance, having ammunition, &c. proportionable, ſhall for the firſt three voyages which the ſaid ſhip ſhall make to any foreign parts, receive a tenth of the cuſtoms called the ſubſidy of tonnage and poundage, payable for merchandize exported and imported in ſuch ſhips; but if after the end of the three firſt voyages, ſhips ſo built ſhall be altered ſo as to become leſs defenſible than they were at firſt, then they ſhall be forfeited and loſt.

By 2 Ann. cap. 9. owners of ſhips might navigate during the war with France, with maſters and only one half of the mariners Engliſh; and by 3 and 4 Ann. cap. 13. any ſhips might be navigated by foreign ſeamen; and foreigners ſerving on board any Engliſh ſhip for two years, were to be deemed natural-born ſubjects, &c.

By 4 Geo. I. cap. 12. and 11 Geo. I. cap. 29. if any officer or mariner belonging to any ſhip or veſſel, ſhall wilfully caſt away, burn or deſtroy the ſhip to which he belongeth, or in any-wiſe direct or procure the ſame to be done, with intent to prejudice a perſon that ſhall have granted any inſurance thereon, or any merchant who ſhall load goods therein, or any owner of ſuch veſſel, the perſons offending ſhall on conviction be adjudged guilty of felony without benefit of clergy.

The 5th of Geo. II. cap. 20. enacts, that no commander of any ſhip outward-bound ſhall receive on board any gunpowder, either as merchandize or ſtores for the voyage, except for his majeſty's ſervice, before ſuch ſhip ſhall be at Blackwall, in the river Thames; and all maſters of ſhips coming into the river, ſhall put on ſhore all powder either before the arrival of their ſhips at the ſaid place, or within twenty-four hours after they come to anchor there, upon pain of forfeiting 5*l.* for every fifty pounds weight of gunpowder on board, and in the like proportion for a leſs quantity. And no guns ſhall be kept loaded with ſhot in merchant-ſhips between London-bridge and Blackwall, or fired before the riſing, or after the ſetting of the ſun, under the penalty of 5*l.* and for every gun ſo fired, 10*l.* And if any pitch, tar, roſin, or

other combuſtible matter, ſhall be heated or melted by fire in any ſhips, every perſon ſo offending, ſhall, for every offence, forfeit 5*l.* And ſhips are liable to be ſearched by an elder brother, appointed by the maſter, wardens, and aſſiſtants of the Trinity-houſe at Deptford. In caſe any ſhip ſhall be moored in the mouth or any other part of St. Saviour's dock, except ſuch ſhips as ſhall be loading or delivering their cargoes, and others, not exceeding two at a time, that ſhall lie at Shipwright-yard, at the north-weſt corner of the ſaid dock, during the time they ſhall be repairing, the maſter of ſuch ſhip ſhall forfeit 20*s.* for every day ſhe ſhall continue to be laid up and moored.

By 6 Geo. II. cap. 29. maſters of ſhips lying in the river Thames, who have occaſion for ballaſt, ſhall pay 1*l.* per ton colliers, other ſhips 1*l.* 3*d.* and foreign ſhips 1*l.* 7*d.* per ton, to the corporation of the Trinity-houſe at Deptford; who ſhall pay ballaſt-men 5*d.* a ton, for raiſing and carrying it, &c. and it ſhall be lawful for any maſter of a ſhip to appoint two perſons to go on board any lighter bringing ballaſt to ſuch ſhip, to inſpect the marks thereof; and every ballaſt-man ſhall immediately before the delivery of ballaſt to any ſhip, trim ſuch lighter, ſo as to make it ſwim at equal marks at the ſtem and ſtern, and pump all the water out, &c. and the maſter, wardens, and aſſiſtants of the Trinity-houſe, are to make good to the maſter the quantity or value of the ballaſt which ſhall be found deficient, or forfeit 30*l.* one moiety to the poor, and the other to the perſon ſuing for it.

The 7th of Geo. II. cap. 15. ordains, that no owners of ſhips ſhall be liable to any loſs by reaſon of embezzlement by the maſter or mariners, of any goods or merchandize ſhipped on board, or for any act done by them, without the privity or knowledge of ſuch owners, farther than the value of the ſhip, and amount of the freight during the voyage, in which ſuch embezzlement of the maſter or mariners ſhall be committed; and if ſeveral perſons ſhall ſuffer damage by the means aforeſaid, and the value of the ſhip and cargo ſhould not be ſufficient to make compenſation; then the freighters ſhall receive ſatisfaction in average, in proportion to their reſpective loſſes, to be aſcertained on a bill in equity, exhibited for a diſcovery thereof, and of the value of ſuch ſhip and freight. But nothing in this act ſhall diſcharge any remedy, which any perſon may have againſt the maſter and mariners, in reſpect of an embezzlement.

NAVIGATION, *ſub marine*, or the art of ſailing under water, is mentioned by Mr. Boyle as the deſideratum of the art of *navigation*. This was attempted, and ſucceſsfully according to him, by Cornelius Drebbel; ſeveral perſons who were in the boat breathing freely all the time. See DIVING-*bell*.

NAVIGATION, *inland*. See CANAL.

NAVIGATOR, in the *Sea-language*, uſually denotes a perſon capable of carrying or guiding a ſhip to any place deſired.

NAVIS, *Argo* NAVIS, or the ſhip *Argo*, in *Aſtronomy*, a conſtellation of the ſouthern hemiſphere. See ARGO.

NAULIUM, in *Antiquity*, a muſical inſtrument otherwiſe called NABLIUM.

NAULUM, among the Romans, properly ſignified *freight*; whence it is uſed to denote a piece of money put into the mouth of a perſon deceaſed, to pay Charon the ferryman for his paſſage: this piece was to be of the current coin of the emperor then reigning; ſo that from it the time of the perſon's death may be known.

NAUMACHIA, *naumachy*, from ναυς, *ſhip*, and μαχη, *fight*, a ſpectacle, or ſhew, among the ancient Romans, repreſenting a ſea-fight.

NAUMACHIA is alſo uſed, by ſome, for a circus encompaſſed with ſeats and porticos; the pit whereof, ſerving as an arena, was filled with water, by means of pipes, for the exhibiting of ſea-fights.

There were ſeveral of theſe *naumachias* at Rome: three built by Auguſtus, one by Claudius, and another by Domitian. Nero's *naumachia* ſerved for the reverſe of his medals.

NAUPLIUS, in *Natural Hiſtory*, a name by which ſome authors have called the NAUTILUS, as well the papyraceous as the chambered kind.

NAUSEA, ναυτια, in *Medicine*, a reaching, or propenſity and endeavour to vomit; ariſing from a loathing of food, excited by ſome viſcous humour that irritates the ſtomach, and urges it to diſcharge itſelf; and accompanied with anxiety about the præcordia, and ſalivation of the mouth.

The word is formed from the Greek ναυτια, of ναυς, ναυτις, *ſhip*; becauſe, people, at the beginning of their voyages, are uſually liable to this diſorder.

A *nauſea* is, when the thoughts or ſight of proper food create a ſickneſs in the ſtomach, and a tendency to vomit.

Nauſea and vomiting only differ from one another, as more or leſs violent. The *nauſea* is properly the effort the ſtomach makes to vomit, which has not always the effect.

Boerhaave defines a *nauſea*, anatomically, to be a retrograde ſpaſmodic motion of the muſcular fibres of the œſophagus, ſtomach, and inteſtines; attended with convulſions of the abdominal muſcles, and the ſeptum tranſverſum.

The uſual cauſes of a *nauſea* and anorexia, are, hard drinking, great heat, a fever, conſumption, laxneſs of the ſtomach occaſioned by tea, &c. alſo narcotics; as tobacco, paſſions of the mind, ſuppreſſion of evacuations inducing a plethora, foul ſtomach, tenacious humours lodged therein, and certain ſwimming or undulatory motions.

NAUTICAL *planiſphere*, a deſcription of the terreſtrial globe upon a plane, for the uſe of mariners. See PLANISPHERE, and *Sea*-CHART.

NAUTICAL *chart*. See *Sea*-CHART.

NAUTICAL *compaſs*. See COMPASS.

NAUTICUS, in *Anatomy*, a muſcle, called alſo TIBIALIS *poſticus*.

NAUTILUS, in *Natural Hiſtory*, the name of a genus of ſhell-fiſh, the characters of which are theſe: it expreſſes, in general, in every ſpecies, the figure of a boat, or veſſel, made for ſwimming on the water; but in the different ſpecies it is of very different figures, roundiſh or oblong, thin or thick, furrowed or ſmooth, and ſometimes is auriculated, ſometimes not. Bonani obſerves, that this genus of ſhell-fiſh is very well named from the Greek ναυτος, which ſignifies both a *fiſh*, and a *ſailor*, for that the ſhells of all the *nautili* carry the appearance of a boat, or ſhip, with a very high poop.

Different authors, among the ancient and modern, have called the *nautilus* by the names of *pompilus*, *nauplius*, *nautilus*, *vinum ſapit*, *polypus teſtaceus*, and the French call it *le coillier*. It is ſuppoſed that men firſt learned the method of ſailing in veſſels, from what they ſaw practiſed by this creature.

We at preſent know two diſtinct genera of *nautilus*, the thin and the thick-ſhelled *nautilus*. The firſt is called *nautilus papyraceus*, and its ſhell ſeems indeed no thicker, or ſtronger, than a piece of paper, when out of the water. This ſpecies is not at all faſtened to its ſhell; but there is an opinion as old as the days of Pliny, that this creature creeps out of its ſhell, and goes on ſhore to feed. When this ſpecies is to ſail, it extends two of its arms on high, and between theſe ſupports a membrane, which it throws out on this occaſion; this ſerves for its ſail, and the two other arms it hangs out of the ſhell, to ſerve occaſionally either as oars, or as a ſteerage; but this laſt office is generally ſerved by the tail. When the ſea is calm, it is frequent to ſee numbers of theſe creatures diverting themſelves with ſailing about in this manner; but as ſoon as a ſtorm ariſes, or any thing gives them diſturbance, they draw in their legs, and take in as much water as makes them ſomewhat heavier than the ſea-water in which they ſwim, and they then ſink to the bottom. The manner of their voiding this abundant water when they would riſe again, is by a number of holes, of which their legs are full.

The other *nautilus*, whoſe ſhell is thick, never quits that habitation. This ſhell is divided into forty or more partitions, which grow ſmaller and ſmaller as they approach the extremity, or center of the ſhell: between every one of theſe cells, and the adjoining ones, there is a communication, by means of a hole in the center of every one of the partitions. Through this hole there runs a pipe, which is of the whole length of the ſhell. It is ſuppoſed by many that the fiſh occaſionally changes the place of its reſidence, by moving from one to another of theſe cells, through this pipe in the little hole; but this is by no means probable, as the body of the fiſh muſt neceſſarily be cruſhed to death, if it were poſſible to make it paſs through ſuch a hole. It ſeems, therefore, much more probable, that the fiſh occupies always the largeſt chamber in its ſhell, that is, it lives in the cavity between the mouth and the firſt partition; and that it never removes out of this, but that all the apparatus of cells, and a pipe of communication, which we ſo much admire, ſerve only to admit occaſionally air, or water, into the ſhell, in ſuch proportion as may ſerve the creature in its intentions of ſinking or ſwimming.

Some authors call this ſhell *concha margaritifera*; but this can be only on occaſion of the fine colour of its inſide, which is more beautiful than any other mother of pearl; for it has not been obſerved that this ſpecies of fiſh ever produced pearls.

It muſt be obſerved that the polypus is by no means to be confounded with the paper-ſhelled *nautilus*, notwithſtanding the great reſemblance in the arms and body of

the enclosed fish; nor is the cornu ammonis, so frequently found foſſile, to be confounded with the thick-shelled *nautilus*, though the concamerations, and general ſtructure of the ſhell, are alike in both; for there are great and eſſential differences between all theſe genera. See CORNU *ammonis*, &c.

The three principal differences of the *nautilus* claſs are, that ſome are papyraceous, ſome are auriculated, and ſome are umbilicated.

The ſeveral known ſpecies of *nautilus* are theſe: 1. The great, ſmooth, and thick *nautilus*. 2. The little *nautilus*, with a ſmooth and thick ſhell. 3. The ſmooth, and thick, umbilicated *nautilus*. 4. The common, concamerated *nautilus*. 5. The furrowed, and empty *nautilus*, with no diaphragms, or ſeparation within. 6. The thin, and flatted, papyraceous *nautilus*. 7. The auriculated *nautilus*, with a wider ſhell. 8. The undulated, and furrowed *nautilus*, with dents on each ſide the edge. 9. The *nautilus*, with a ridged and ſerrated back. This laſt ſpecies is often found in the cabinets without its outer coat, and the ſhell then looks all over like the moſt beautiful mother of pearl. Hiſt. Natur. Eclair. part ii. p. 249. See *Tab. of Foſſil, Claſs* 9. and *Tab. of Shells*, N° 8.

NAVY, the fleet or ſhipping of a prince or ſtate. See FLEET.

Several articles and orders for the government of the *navy* are eſtabliſhed by 13 Car. II. c. 9. and 22 Geo. II. c. 33. which are as follow:

1. Officers are to cauſe public worſhip, according to the liturgy of the church of England, to be ſolemnly performed in their ſhips, and take care that prayers and preaching by the chaplains be performed diligently, and that the Lord's day be obſerved. 2. Perſons guilty of profane oaths, curſing, drunkenneſs, uncleanneſs, &c. to be puniſhed as a court martial ſhall think fit. 3. If any perſon ſhall *give* or *hold intelligence to* or with an enemy *without leave*, he ſhall ſuffer *death*. 4. If any letter or meſſage from an enemy be conveyed to any in the fleet, and he ſhall not in *twelve hours* acquaint his ſuperior officer with it, or if the ſuperior officer being acquainted therewith, ſhall not reveal it to the commander in chief, the offender ſhall ſuffer *death*, or ſuch puniſhment as a court martial ſhall impoſe. 5. Spies and perſons *endeavouring to corrupt any one in the fleet*, ſhall ſuffer *death*, or ſuch puniſhment as a court martial ſhall impoſe. 6. No perſon ſhall relieve an enemy with money, victuals, or ammunition, on like penalty. 7. All papers taken on board a prize ſhall be ſent to the court of admiralty, &c. on penalty of forfeiting the ſhare of the prize, and ſuch puniſhment as a court martial ſhall impoſe. 8. No perſon ſhall take out of any prize any money or goods, unleſs for better ſecuring the ſame, or for the neceſſary uſe of any of his majeſty's ſhips, before the prize ſhall be condemned; upon penalty of forfeiting his ſhare, and ſuch puniſhment as ſhall be impoſed by a court martial. 9. No perſon on board a prize ſhall be *ſtripped* of his cloaths, *pillaged*, *beaten*, or *ill treated*, upon pain of ſuch puniſhment as a court martial ſhall impoſe. 10. Every commander, who, upon ſignal or order of fight or fight of any ſhip which it may be his duty to engage, or who, upon likelihood of engagement, ſhall *not make neceſſary preparations* for fight, and *encourage the inferior officers and men to fight*, ſhall ſuffer *death*, or ſuch puniſhment as a court martial ſhall deem him to deſerve. And if any perſon ſhall *treacherouſly or cowardly* yield or cry for quarter, he ſhall ſuffer *death*. 11. Every perſon who ſhall *not obey the orders* of his ſuperior officer, *in time of action*, to the beſt of his power, ſhall ſuffer *death*, or ſuch puniſhment as a court martial ſhall deem him to deſerve. 12. Every perſon, who, in time of action, ſhall *withdraw* or *keep back*, or *not come into the fight*, or do his utmoſt to take or deſtroy any ſhip which it ſhall be his duty to engage, and to aſſiſt every ſhip of his majeſty or his allies, which it ſhall be his duty to aſſiſt, ſhall ſuffer *death*. 13. Every perſon, who through cowardice, &c. ſhall forbear to purſue the chace of an enemy, &c. or ſhall not aſſiſt or relieve *a known friend in view*, to the utmoſt of his power, ſhall ſuffer *death*. 14. If any perſon ſhall delay or diſcourage any action or ſervice commanded, upon pretence of arrears of wages, or otherwiſe, he ſhall ſuffer *death*, or ſuch puniſhment as a court martial ſhall deem him to deſerve. 15. Every perſon who ſhall *desert to the enemy*, or *run away with any ſhip, ordnance*, &c. to the weakening of the ſervice, or yield up the ſame cowardly or treacherouſly to the enemy, ſhall ſuffer *death*. 16. Every perſon who ſhall *desert*, or *entice others* ſo to do, ſhall ſuffer *death*, or ſuch puniſhment as a court martial ſhall think fit. If any commanding officer ſhall receive a deſerter, after diſcovering him to be ſuch, and ſhall not with ſpeed give notice to the captain of the ſhip to which he belongs, or if the ſhip is at a conſiderable diſtance, to the ſecretary of the admiralty, or commander in chief, he ſhall be caſhiered. 17. Officers and ſeamen of ſhips appointed for convoy of merchant ſhips, or of any other, ſhall diligently attend upon that charge according to their inſtructions; and whoſoever ſhall not faithfully perform their duty, and defend the ſhips in their convoy, or refuſe to fight in their defence, or run away cowardly, and ſubmit the ſhips in their convoy to hazard, or exact any reward for conveying any ſhip, or miſuſe the maſter or mariners, ſhall make reparations of damages, as the court of admiralty ſhall adjudge, and be puniſhed criminally by death, or other puniſhment, as ſhall be adjudged by a court martial. 18. If any officer ſhall receive or permit to be received on board any goods or merchandiſe, other than for the uſe of the ſhip, except gold, ſilver, or jewels, and except goods belonging to any ſhip which may be ſhipwrecked, or in danger thereof, in order to the preſerving them for the owners, and except goods ordered to be received by the lord high admiral, &c. he ſhall be caſhiered, and rendered incapable of farther ſervice. 19. Any perſon making or endeavouring to make any mutinous aſſembly, ſhall ſuffer *death*. Any perſon uttering words of ſedition or mutiny ſhall ſuffer *death*, or ſuch puniſhment as a court martial ſhall deem him to deſerve. If any officer, mariner, or ſoldier, in or belonging to the fleet ſhall behave himſelf with contempt to his ſuperior officer, *being in the execution of his office*, he ſhall be puniſhed according to the nature of his offence by the judgment of a court martial. 20. Any perſon concealing any traiterous or mutinous practice or deſign, ſhall ſuffer *death*, or ſuch puniſhment as a court-martial ſhall think fit. Any perſon concealing any traiterous or mutinous words, or any words, practice, or deſign, *tending to the hindrance of the ſervice*, and not forthwith revealing the ſame to the commanding officer; or being preſent at any mutiny or ſedition, ſhall not uſe his utmoſt endeavours to ſuppreſs the ſame, ſhall be puniſhed as a court-martial ſhall think he deſerves. 21. Any perſon finding cauſe of complaint of the unwholeſomeneſs of victuals, or upon other juſt ground, he ſhall *quietly* make the ſame known to his ſuperior, who, as far he is able, ſhall cauſe the ſame to be preſently remedied; and no perſon upon any ſuch or other pretence ſhall attempt to ſtir up any diſturbance, upon pain of ſuch puniſhment as a court martial ſhall think *fit to inflict*. 22. Any perſon ſtriking any his ſuperior officer, or drawing or offering to draw or lift up any weapon againſt him, *being in the execution of his office*, ſhall ſuffer death. And any perſon preſuming to quarrel with any his ſuperior officer, *being in the execution of his office*, or diſobeying any lawful command of any his ſuperior officer, ſhall ſuffer *death*, or ſuch other puniſhment as ſhall be inflicted upon him by a court martial. 23. Any perſon quarrelling or fighting with any other perſon in the fleet, or uſing reproachful or provoking ſpeeches or geſtures, ſhall ſuffer ſuch puniſhment as a court martial ſhall impoſe. 24. There ſhall be no waſteful expence or embezzlement of any powder, ſhot, &c. upon penalty of ſuch puniſhment as by a court martial ſhall be found juſt. 25. Every perſon burning or ſetting fire to any magazine, or ſtore of powder, ſhip, &c. or furniture thereunto belonging, not then appertaining to an enemy, ſhall ſuffer death. 26. Care is to be taken that through wilfulneſs or negligence no ſhip be ſtranded, run upon rocks or ſands, or ſplit or hazarded; upon pain of *death*, or ſuch puniſhment as a court martial ſhall deem the offence to deſerve. 27. No perſon ſhall ſleep upon his watch, or negligently perform his duty, or forſake his ſtation, *upon pain of death*, or ſuch puniſhment as, &c. 28. Murder. 29. And buggery or ſodomy ſhall be puniſhed with *death*. 30. Robbery ſhall be puniſhed with *death*, or otherwiſe, as a court martial ſhall find meet. 31. Every perſon *knowingly* making or ſigning, or commanding, counſelling, or procuring the making or ſigning any falſe muſter, ſhall be caſhiered, and rendered incapable of farther employment. 32. Provoſt martial refuſing to apprehend or receive any criminal, or ſuffering him to eſcape, ſhall ſuffer ſuch puniſhment as a court martial ſhall deem *him* to deſerve. And all others ſhall do their endeavours to detect and apprehend all offenders, upon pain of being puniſhed by a court martial. 33. If any flag-officer, captain, commander, or lieutenant, ſhall behave in a ſcandalous, infamous, cruel, oppreſſive, or fraudulent manner, *unbecoming his character*, he ſhall be diſmiſſed. 34. Every perſon in actual ſervice and full pay, guilty of mutiny, deſertion, or diſobedience, in *any* part of his majeſty's dominions on ſhore, when in actual ſervice, relative to the fleet, ſhall be liable to be tried by a court martial, and ſuffer the like puniſhment as if the offence had been committed at ſea. 35. Every perſon in actual ſervice and full pay, committing upon ſhore, in *any* place out of his majeſty's dominions, any crime puniſhable

able by these articles, shall be liable to be tried and punished as if the crime had been committed at sea. 36. All other crimes not capital, not mentioned in this act, shall be punished according to the laws and customs used at sea. No person to be imprisoned for longer than two years. Court martial not to try any offence (except the 35th, 34th, and 35th articles) not committed upon the main sea, or in great rivers beneath the bridges, or in any haven, &c. within the jurisdiction of the admiralty, or by persons in actual service and full pay, except such persons and offences, as in 5th article; nor to try a land officer or soldier on board a transport ship. The lord high admiral, &c. may grant commissions to any officer commanding in chief any fleet, &c. to call courts martial, consisting of commanders and captains. And if the commander in chief shall die or be removed, the officer next in command may call courts martial. No commander in chief of a fleet, &c. of more than five ships, shall preside at any court martial in foreign parts, but the officer next in command shall preside. If a commander in chief shall detach any part of his fleet, &c. he may impower the chief commander of the detachment to hold courts martial during the separate service. If five or more ships shall meet in foreign parts, the senior officer may hold courts martial and preside thereat. Where it is improper for the officer next to the commander in chief to hold or preside at a court martial, the third officer in command may be impowered to preside at or hold a court martial. No court martial shall consist of more than *thirteen*, or less than *five* persons. Where there shall not be less than three, and yet not so many as five of the degree of a port captain, or superior rank, the officer who is to preside may call to his assistance as many commanders under the degree of a port captain, as together with the port captains, shall make up the number five, to hold the court martial. After trial begun, no member of a court martial shall go on shore, until sentence, except in case of sickness, upon pain of being cashiered. Proceedings shall not be delayed, if a sufficient number remain to compose the court, which shall sit from day to day (except Sunday), till sentence be given. The judge advocate, and all officers constituting a court martial, *shall be upon oath*. Persons refusing to give evidence may be imprisoned. Sentence of death within the Narrow Seas (except in case of mutiny) shall not be put in execution till a report be made to the lord high admiral, &c. Sentence of death beyond the Narrow Seas, shall not be put in execution but by order of the commander in chief of the fleet, &c. Sentence of death in any squadron, detached from the fleet, shall not be put in execution (except in case of mutiny) but by order of the commander of the fleet, or lord high admiral, &c. And sentence of death passed in a court martial, held by the senior officer of five or more ships met in foreign parts (except in case of mutiny) shall not be put in execution but by order of the lord high admiral, &c. The powers given by the said articles shall remain in force with respect to crews of ships wrecked, lost, or destroyed, until they be discharged or removed into another ship, or a court martial shall be held to inquire of the causes of the loss of the ship. And if upon inquiry it shall appear, that all or any of the officers and seamen did their utmost to save the ship, and behaved obediently to their superior officers, their pay shall go on: as also shall the pay of officers and seamen taken by the enemy, having done their best to defend the ship, and behaved obediently. If any officer shall receive any goods on board, contrary to the 18th article, he shall farther forfeit the value of such goods, or 500*l.* at the election of the informer; one moiety to the informer, the other to Greenwich hospital. For other regulations relating to the *navy*, see MARINERS.

For the method of supplying the navy, see MANNING *the fleet.*

The royal *navy* of Great Britain is conducted, under the direction of the lords of the admiralty, by the following principal officers, who are commissioners, and compose the board for managing the business thereof. 1. *Comptroller* of the *navy*, who attends and comptrols the payment of all wages, is to know the rates of stores, &c. 2. *Surveyor* of the *navy*, who is to know the state of all stores, to supply what is wanting, to estimate repairs, charge boatswains, &c. with the stores they receive, &c. There have been generally two joint-surveyors. 3. *Clerk of the acts*, whose business is to record all orders, contracts, bills, warrants, &c. 4. *Comptroller* of the treasurer's accounts. 5. *Comptroller* of the victualling accounts. 6. *Comptroller* of the store-keeper's accounts. 7. One extra commissioner. The annual appointment of each commissioner is 500*l.* In time of war, or great naval exertion, there are other additional extra commissioners; and now, viz. in 1781, there are two, exclusive of those above enumerated. There are also three commissioners for the out-ports, residing at Portsmouth, Plymouth, and Chatham; and in time of war commissioners are appointed to reside at some of the principal yards abroad. The *treasurer* of the *navy*, who has an appointment of 2000*l.* a year, and whose business is to receive money out of the exchequer, and to pay all the charges of the *navy*, by warrant from the principal officers. Each of these commissioners and officers have a number of subordinate clerks, with various salaries.

The *navy* was anciently victualled by contract; but the victualling is now under commissioners, who keep their office on Tower-hill. See VICTUALLING-*office*.

For the several yards belonging to his majesty's navy, see DOCK-*yards.*

NAVY, or *victualling bills*, are bills or orders for the payment of money, issued by the commissioners of the *navy*, and other boards in that department, on the treasurer of the *navy*, for stores purchased, &c. These bills are not payable at any fixed time, but bear interest at the rate of 4 *per cent.* after six months, from the date of their being registered at the respective offices; and they have generally been paid off within eighteen months, or two years, from the time of their being issued.

The NAVY-*office* is the place where the chief business of the *navy* is transacted by the officers and commissioners.

NAVY denotes also the collective body of officers employed in his majesty's service.

NAZAREATE, or NAZARITESHIP, the state and condition of a Nazarite or Nazarean among the Jews. See NAZARITE.

The *Nazareate* was a state of separation from the rest of mankind; particularly in three things. 1. In that the person devoted hereto drank no wine. 2. In that they did not shave their heads, but let the hair grow. 3. In avoiding the touch of dead people, which they held a defilement.

The *Nazareate* was of two kinds; the one temporary, or for a certain number of days; the other for life. The rabbins inquire what the term of the temporary *Nazareate* was, and determine it by the Cabbala: for since, in Scripture, Numbers vi. 5. where it is said, *Domino sanctus erit*, the Hebrew verb יִהְיֶה *erit*, consists of four letters; the first and third whereof, taken as numeral letters, do each make 10, and the rest each 5, all together 30; the term of the *Nazareate*, say they, was 30 days.

NAZARITE, or NAZARENE, in the *Old Testament*, is used for a person distinguished and separated from the rest, by something extraordinary, either his sanctity, dignity, or vows.

The word comes from the Hebrew נָזַר *nazar*, *to distinguish*, *separate*; in which it differs from Nazarean, an inhabitant of the country called *Nazareth*, which comes from נָצַר *notzar*, *or natzar*, *to save*, *preserve*.

In the book of Numbers, chap. vi. we find the vow of a *Nazarite* described, i. e. the vow wherby a man or woman separated themselves to the Lord; and the conditions or effects thereof as to abstinence, &c.

NAZARITES, NAZARENES, or NAZAREANS, were likewise a kind of sectaries in the church, in the first ages thereof.

St. Epiphanius tells us, the *Nazareans* were the same with the Jews in every thing relating to the doctrine and ceremonies of the Old Testament; and only differed from them in this, that they added Christianity to those; professing to believe, that Jesus Christ was the Messiah.

There were two kinds of *Nazareans*; the one *pure*, who kept the law of Moses and Christianity together, and who were not placed by the ancient Christians in the register of heretics, but first ranked in this class by Epiphanius, in the fourth century; the other, real EBIONITES.

Ecclesiastical writers tell us, that St. Matthew preached the Gospel to the Jews at Jerusalem, and the rest of Palestine, in their own language; and that accordingly they had his Gospel written in the Hebrew of that time. And St. Epiphanius adds, that this Gospel was preserved entire among the *Nazareans*; only he doubts whether they might not have retrenched the genealogy of Jesus Christ, which was not in the copy of the Ebionites. St. Jerom, who translated it out of Hebrew into Greek and Latin, says, a great many people took the Hebrew Gospel, used by the *Nazareans* and Ebionites, to be the original of St. MATTHEW.

Hence Baronius, in his Annals, says, if the Vulgate Latin version were to be reformed, it should rather be done by the Hebrew original, than by the Greek, which is but a copy. Casaubon treats this opinion of Baronius as highly impious; as not being able to conceive how the authority of the Greek version should depend on a text quite lost. He adds, that it was never used by any but the *Nazareans*, Ebionites, and some other heretics; and

that it was full of fables, as having been altered and corrupted by those heretics.

The reader will find an accurate and satisfactory account of this Gospel in Mr. Jones's Method of settling the canonical Authority of the New Testament.

Mosheim observes, that the term *Nazarenes* was not originally the name of a sect, but that which distinguished the disciples of Jesus in general. Nevertheless, those who, after their separation from their brethren, retained the title of *Nazarenes*, differed much from the true disciples of Christ, to whom that name had been originally given. They held that Christ was born of a virgin, and was also in a certain manner united to the divine nature; they refused to abandon the ceremonies prescribed by the law of Moses, but were far from attempting to impose the observance of these ceremonies upon the Gentile Christians; they rejected also those additions that were made to the Mosaic institutions by the Pharisees, and the doctors of the law; and from hence we see the reason why the greatest part of the Christians treated the *Nazarenes* with a more than ordinary degree of gentleness and forbearance. Mosheim's Eccl. Hist. vol. i. p. 173, 8vo edit.

NE ADMITTAS, a writ directed to the bishop, in behalf of the plaintiff, or defendant, in a cause where a quare impedit, or affize of darrein presentment, is depending; when either party fears, that the bishop will admit the other's clerk during the suit between them.

This writ should be brought within six months after the church becomes void, before the bishop may present by lapse; and upon granting it, another writ is issued to the chief justice of the common pleas, to certify the king in chancery, whether there be any plea before him and the other justices, between the parties, &c.

NEALED, at *Sea*, is used when the sounding is deep water close to the shore: it is then said to be *nealed to*; as also when the shore is sandy, clayey, oozy, or foul and rocky.

NEALING, or rather ANNEALING, a term used for the preparing of several matters, by heating or baking them in an oven, or the like.

NEALING *of glass* is the baking of glass, to dry, harden, and give it the due consistence, after it has been blown, and fashioned into the proper works.

This is usually performed in a kind of tower, called the *leer*, built over the melting furnace. See GLASS.

NEALING *of glass* is also used for the art of staining glass with metalline colours.

One fine use of silver, says Mr. Boyle, was only discovered since the art of *annealing* upon glass came to be practised. For prepared silver, or even the crude metal, being burnt on a glass plate, will tinge it of a fine yellow, or golden colour. And there are several mineral earths, and other coarse matters, of use in this art, which, by means of fire, impart transparent colours to glass, and sometimes very different ones from those of the bodies themselves.

NEALING *of steel*, is the heating it in the fire to a blood-red heat; and then taking it out, and letting it cool gently of itself.

This is done to make it softer, in order to engrave or punch upon it. See TEMPERING, and ENGRAVING.

NEALING is also used for the act or act of burning or baking earthen or other ware in an oven.

The miners at Mendip, when they meet with a rock they cannot cut through, *anneal* it, by laying on wood and coal, and contriving the fire so that they quit the mine before the operation begins; it being dangerous to enter it again before it be quite cleared of the smoke. Phil. Trans. N° 39. p. 769.

NEALING *of tile* is used in ancient statutes, for the burning of tile.

The word is formed of the Saxon *onælinz*, *accendere*, *to light*, *burn*.

NEAP, or NEEP-*tides*, are those tides which happen when the moon is in the middle of the second and fourth quarters.

The *neap-tides* are low tides, in respect of their opposites, the spring-tides.

As the highest of the spring-tides is three days after the full or change, so the lowest of the *neap* is four days before the full or change. On which occasion the seamen say, that it is *deep neap*. See TIDE.

NEAPED, when a ship wants water, so that she cannot get out of the harbour, off the ground, or out of the dock; the seamen say, *She is neaped*, or *beneaped*.

NEAPOLITAN *disease*, a name given by many authors to the venereal disease; and from hence came the name of the *Neapolitan* ointment, which is a mixture of quicksilver, and other things, into an ointment, intended as a cure for it.

NEAR, or NE NEAR, at *Sea*, a word of command from him that conds the ship, to the man at the helm, requiring him to let her fall to the leeward.

NEAT, or NET *weight*, the weight of a commodity alone, clear of the cask, bag, case, and even filth. See NET, and WEIGHT.

NEBEL, or NEVEL, in the *Jewish Antiquities*, a kind of musical instrument. See *Tab. Musica, fig.* 7. See NABLUM.

NEBRITES, in *Natural History*, a name given by the ancients to a stone held sacred to Bacchus. It was of the brownish yellow colour of the skin of the young fawn, with some variegations, and was semi-pellucid: it seems to have been the same with some of our agates, with a yellow ground; the ancients, however, do not appear to have been very determinate in their accounts of it; for Pliny mentions another kind of it, which was black.

NEBRUS, in *Natural History*, a name given by the ancients to the *hinnulus*, a deer of one year old. In the next year it is called *pastalon*; in the third *dicrota*; and in the fourth *eladia*; the word *cerastes* was used as the name of this animal when of a greater age than this.

NEBULGEN, a word used by some of the chemical writers, to express what they call a salt generated by the moisture of the air falling upon stones in the fields, and there indurated by the heat of the sun into the form of a dry salt.

NEBULOUS, *cloudy*, in *Astronomy*, a term applied to certain of the fixed stars, which shew a dim, hazy light; being less than those of the sixth magnitude, and therefore scarce visible to the naked eye, to which, at best, they only appear like little dusky specks or clouds.

Through a moderate telescope, these *nebulous* stars plainly appear to be congeries or clusters of several little stars.

In the *nebulous* star, called *Præsepe*, in the breast of Cancer, there are reckoned thirty-six little stars, three of which Mr. Flamsteed gives us in his Catalogue.

In the *nebulous* star of Orion are reckoned 21. F. le Compte adds, that in the Pleiades are 403; 12 in the star in the middle of Orion's sword; in the extent of two degrees of the same constellation, 500; and 2500 in the whole constellation. See ORION, &c.

NEBULY, *nebulee*, in *Heraldry*, when a coat is charged with several little figures, in form of clouds, running within one another; or, when the outline of a bordure, ordinary, &c. is indented, or waved; as represented in *Tab. Herald. fig.* 32. See NUBECULA *linea*.

NECESSARIANS denote those who are advocates for the doctrine of *philosophical* NECESSITY.

NECESSARIO, in the *Italian Music*. The word is prefixed to certain parts in musick, as *a doi violini necessario*, i. e. *that must be played by two violins*; *canto necessario* is used to signify much the same as CONCERTANTE.

Every mode has certain chords, which may be called its necessary, or essential chords.

NECESSARY, in a philosophical sense, that which cannot but be, or cannot be otherwise.

The schoolmen make a great many kinds or divisions hereof: as, *necessary in existing*; when there is a cause from which an effect must necessarily follow: *necessary in predicating*; *necessary in being*, &c.

There is also a *logical necessary*; *physical necessary*; and there are *metaphysical* and *moral necessaries*.

NECESSITY, what is done by a necessary cause, or a power that is irresistible.

In this sense *necessity* stands opposed to LIBERTY.

Necessity is usually confounded with constraint; yet, in effect, *necessity*, according to Rochefoucault, differs from constraint in this, that the former is joined with the pleasure and inclination of the will, to which constraint is contrary.

Simplicius, after Plato and Epictetus, distinguishes two kinds of *necessity*; the one *violent* or *coactive*, which is opposite to liberty; the other *spontaneous* or *voluntary*, very consistent with it: this latter, adds he, is that which necessitates all things to act according to their nature, as being connatural to them; since ἀυτόματον, a thing that is self-moved, must of *necessity* be moved according to its own nature, i. e. spontaneously. This distinction is admitted by many of the divines, particularly by St. Augustine, who urges it against the Pelagians, as is shewn by Jansenius.

The schools distinguish a *physical necessity*, and a *moral necessity*; and a *simple*, *absolute necessity*, and a *relative* one.

NECESSITY, *physical*, is the want of a principle, or of a natural means necessary to act; which is otherwise called a *physical* or *natural impotence*.

NECESSITY, *moral*, is only a great difficulty; such as that arising from a long habit, a strong inclination, or violent passion.

NECESSITY, *simple*, or *absolute*, is that which has no dependence on any state or conjuncture, or any particular situation of things, but is found every where,

and in all the circumſtances in which the agent can be ſuppoſed.

Such is in a blind man the *neceſſity* he is under of not diſtinguiſhing colours.

NECESSITY, *relative*, is that which places a man in a real incapacity of acting, or not acting, in thoſe circumſtances, and that ſituation he is found in; though in other circumſtances, and another ſtate of things, he might act, or not act.

Such, in the opinion of the Janſeniſts, is the *neceſſity* of doing evil in a man, who, with a violent paſſion, has only a feeble grace to reſiſt it; or the *neceſſity* of doing well in a man, who, having grace of ſeven or eight degrees of ſtrength, has only concupiſcence of two or three degrees to withſtand.

All theſe kinds of *neceſſity* are oppoſite to liberty; ſince, even in the laſt, it is as impoſſible for a man to act, or not act, as if he were in a ſtate of *abſolute, ſimple*, and *phyſical neceſſity*.

The ſchoolmen admit other ſpecies of *neceſſity*; *antecedent, concomitant, conſequent*, &c.

NECESSITY, *antecedent*, is that ariſing from an antecedent cauſe, neceſſarily operating. Such is the *neceſſity* of the ſun's riſing to-morrow morning.

NECESSITY, *concomitant*, ariſes from an antecedent and neceſſary cauſe, but depends on the circumſtances of the effect; the effect all the while being free. Thus it is neceſſary Peter ſit, ſuppoſing he is ſitting.

NECESSITY, *metaphyſical* or *philoſophical*, is a term that has been much uſed by modern writers; and which ſome have defined to be, that by which a thing cannot but be, or whereby it cannot be otherwiſe. But a much approved author on this ſubject objects againſt this definition, and obſerves, that *philoſophical neceſſity* is really nothing elſe than the full and fixed connection between the things ſignified by the ſubject and predicate of a propoſition, which affirms ſomething to be true; ſo that it is in no reſpect different from their certainty. When there is ſuch a connection, then the thing affirmed in the propoſition is neceſſary in a philoſophical ſenſe; whether any oppoſition or contrary effort be ſuppoſed or ſuppoſable in the caſe, or no. When the ſubject and predicate of the propoſition, which affirms the exiſtence of any thing, either ſubſtance, quality, act, or circumſtance, have a full and certain connection, then the exiſtence of that thing is ſaid to be neceſſary in a metaphyſical ſenſe.

Thoſe that are commonly called *Neceſſarians* allow no other liberty to man, that is not reſtrained by this kind of *neceſſity*: and when they conſider intelligent beings as the ſubjects of it, ſome of them diſtinguiſh it into *moral* and *natural neceſſity*. *Moral neceſſity* is uſed in a variety of ſenſes: ſometimes for a *neceſſity* of moral obligation; and often for great obligation in point of intereſt: ſometimes by *moral neceſſity* is meant that apparent connection of things, which is the ground of moral EVIDENCE; and ſo it is diſtinguiſhed from *abſolute neceſſity*, or that ſure connection of things, that is a foundation for infallible certainty: and ſometimes by *moral neceſſity* is meant that *neceſſity* of connection and conſequence, which ariſes from ſuch moral cauſes, as the ſtrength of inclination or motives, and the connection, ſubſiſting in many caſes, between theſe and certain volitions and actions. By *natural neceſſity*, as applied to men, they underſtand ſuch *neceſſity* as men are under, through the force of natural cauſes; in contradiſtinction to thoſe that are called moral cauſes, ſuch as habits and diſpoſitions of the heart, and moral inducements and motives.

Mr. Hobbes, who is ſaid to have been the firſt who underſtood and maintained the proper doctrine of *philoſophical neceſſity*, gives the following account of it, in his Leviathan, p. 108. Liberty and *neceſſity* are conſiſtent: as in the water, that hath not the liberty, but a *neceſſity* of deſcending in the channel; ſo likewiſe in the actions which men voluntarily do; which, becauſe they proceed from their will, proceed from liberty; and yet, becauſe every act of man's will, and every deſire and inclination, proceedeth from ſome cauſe, and that from another cauſe, in a continual chain (whoſe firſt link is in the hand of God, the firſt of all cauſes), proceed from *neceſſity*: ſo that to him, who could ſee the connection of thoſe cauſes, the *neceſſity* of all men's voluntary actions would appear manifeſt: and, therefore, God, that ſeeth and diſpoſeth all things, ſeeth alſo, that the liberty of man, in doing what he will, is accompanied with the *neceſſity* of doing that which God will, and no more or leſs: for though men may do many things, which God does not command, nor is, therefore, the author of them, yet they can have no paſſion, will, or appetite to any thing, of which appetite God's will is not the cauſe; and did not his will aſſure the *neceſſity* of man's will, and conſequently of all that on man's will dependeth, the liberty of men would be a contradiction and impediment to the omnipotence and liberty of God.

Mr. Collins, one of the moſt admired writers on the ſubject of *neceſſity*, has ſtated the queſtion concerning human liberty in the following manner: man, he ſays, is a neceſſary agent, if all his actions are ſo determined by the cauſes preceding each action, that not one paſt action could poſſibly not have come to paſs, or have been otherwiſe than it hath been; nor one future action can poſſibly not come to paſs, or be otherwiſe than it ſhall be. But he is a free agent, if he is able, at any time, under the circumſtances and cauſes he then is, to do different things; or, in other words, if he is not unavoidably determined, in every point of time, by the circumſtances he is in, and cauſes he is under, to do that one thing he does, and not poſſibly to do any other. According to this ſtate of the queſtion, he undertakes to prove, that man is a neceſſary agent; and that there neither is nor can be ſuch thing as liberty. 1. He appeals to experience; alledging, that, though the vulgar urge this in proof of liberty, it is not a proof it: that many celebrated philoſophers and theologers, both ancient and modern, have given definitions of liberty, that are conſiſtent with fate or *neceſſity*: that ſome great patrons of liberty do, by their conceſſions in this matter, deſtroy all arguments from experience: that all the actions of men may be ranked under the four heads of perception, judging, willing, and doing as we will; and that experience does not prove any of theſe to be free; and that experience not only does not prove liberty, but, on the contrary, men may ſee by experience, that they are neceſſary agents. It is, ſays he, matter of experience, that man is ever determined in his willing; we experience perfect *neceſſity*; and they, who think liberty a matter of experience, yet allow that the will follows the judgment of the underſtanding, and that, when two objects are preſented to a man's choice, one whereof appears better than the other, he cannot chuſe the worſt. 2. Man is a neceſſary agent, becauſe all his actions have a beginning; for whatever has a beginning muſt have a cauſe, and every cauſe is a neceſſary cauſe: and if any action whatſoever can be done without a cauſe, then effects and cauſes have no neceſſary relation; and, conſequently, we ſhould not be neceſſarily determined in any caſe at all. 3. Liberty would not be a perfection, but an imperfection; whereas, on the contrary, *neceſſity* is an advantage and a perfection. 4. Liberty is inconſiſtent with the divine preſcience; for if God foreknows the exiſtence of any things, as it depends on its own cauſes, that exiſtence is no leſs neceſſary, than if it were the effect of his decree: for it no leſs implies a contradiction, that cauſes ſhould not produce their effects, than that an event ſhould not come to paſs, which is decreed by God.

This argument for *neceſſity* has been urged by a variety of writers; and the advocates for liberty have felt its force, and endeavoured to obviate it. Some have actually given up the divine preſcience: ſome have allowed the ſeeming contradiction, implied in the foreknowledge of a contingent event, and have acknowledged themſelves incapable of removing it: others have endeavoured to reconcile the foreknowledge of God and the liberty of man, by alledging, that there is a great difference between God's foreknowledge and his decrees, with regard to the *neceſſity* of future events; for God's preſcience has no influence at all on our actions: his infallible judgment, concerning contingent truths, does no more alter the nature of the things, and cauſe them to be neceſſary, than our judging right, at any time, concerning a contingent truth, makes it ceaſe to be contingent; or, than our ſenſe of a preſent truth is any cauſe of its being true or preſent.

In the argument, ſays Dr. Clarke, drawn againſt liberty from the divine preſcience, it muſt not firſt be ſuppoſed that things are in their own nature neceſſary; but from the divine preſcience or power of judging infallibly (which power is as much more extenſive and infallible than in man, as the divine nature and underſtanding are ſuperior to our's), concerning free events, it muſt be proved, that things otherwiſe ſuppoſed free, will, therefore, unavoidably become neceſſary; which can no more be proved, than it can be proved that an action, ſuppoſed at this preſent time to be free, is yet (contrary to the ſuppoſition) at the ſame time neceſſary; becauſe, in all paſt time, whether foreknown or not foreknown, it could not, upon that very ſuppoſition of its being now freely done, but be future.

In another place, he acknowledges, that, though it is impoſſible for us to explain diſtinctly the manner how God can foreſee future events, without a chain of neceſſary cauſes, yet we may form ſome general notion of it. For, as a man, who has no influence over another perſon's actions, and yet often perceives before hand what

that

that other will do; and a wiſer and more experienced man will ſtill, with greater probability, foreſee what another, whoſe diſpoſition he is perfectly acquainted with, will in certain circumſtances do; and an angel, with ſtill much leſs degree of error, may have a farther proſpect into men's future actions: ſo it is very reaſonable to apprehend, that God, without influencing men's wills by his power, yet by his foreſight cannot but have as much more certain a knowledge of future free events than either men or angels can poſſibly have, as the perfection of his nature is greater than that of their's. The certainty of foreknowledge, ſays this excellent writer, does not cauſe the certainty of things, but is itſelf founded on the reality of their exiſtence; nor does it imply any other certainty than ſuch as would be equally in things, though there was no foreknowledge; nor again does this certainty of event, in any ſort, imply *neceſſity*. To the ſame purpoſe, Origen has long ago obſerved, that preſcience is not the cauſe of things future, but their being future is the cauſe of God's preſcience that they will be.

It cannot reaſonably be diſputed, that there is an eſſential difference between the foreknowledge and permiſſion of events, and the preordination and production of them: and the ſcheme of *neceſſity* ſeems directly to charge God with being the efficient cauſe or author of thoſe vices and evils, which ariſe from circumſtances and connections of his previous and abſolute appointment. Indeed, many of the advocates of this ſcheme will not admit the conſequence that ſeems to be fairly deducible from their opinion; however, Dr. Prieſtley very candidly allows it. It certainly (ſays he) ſounds harſh to vulgar ears to ſay, that in all thoſe crimes that men charge themſelves with, and reproach themſelves for, God is the agent; and that, in ſuch caſes, they are in reality no more agents, than a ſword is an agent when employed to commit a murder. It does require ſtrength of mind not to ſtartle at ſuch a concluſion; but then it requires nothing but ſtrength of mind; i. e. ſuch a view of things as ſhall carry us beyond firſt and fallacious appearances.

5. Another argument in favour of *neceſſity* is the following: if man was not a neceſſary agent, determined by pleaſure and pain, there would be no foundation of rewards and puniſhments, which are the eſſential ſupports of ſociety. Theſe would be uſeleſs, becauſe if men were free or indifferent to pleaſure and pain, they could be no motives to a man to do or forbear any action.

6. Another argument of the ſame kind is deduced from the nature of morality: for if man was not a neceſſary agent, determined by pleaſure and pain, he would have no notion of morality, or motive to practiſe it; and if he were indifferent to pleaſure and pain, he would have no rule to go by, and might never judge, will, and practiſe right. Every act of the will, it is ſaid, is excited by ſome motive, which motive is the cauſe of that act: and if volitions are properly the effects of motives, then they are neceſſarily connected with their motives: whence it is inferred, that volition is neceſſary, and doth not proceed from any ſelf-determining power in the will. This argument has been illuſtrated and urged in all its force by many modern writers, from M. Leibnitz to Dr. Prieſtley, the laſt and moſt zealous advocate for *neceſſity*: and it has often been anſwered by Dr. Clarke and others, who have ſtrenuouſly maintained, that liberty is perfectly conſiſtent with men's acting from a regard to motives.

Suppoſing, ſays Dr. Price, a power of ſelf-determination to exiſt, it is by no means neceſſary that it ſhould be exerted without a regard to any end or rule: on the contrary, it can never be exerted without ſome view or deſign. Whoever acts, means to do ſomewhat. The power of determining ourſelves, by the very nature of it, wants an end or rule to guide it; and no probability or certainty of its being exerted agreeably to a rule can have the leaſt tendency to infringe or diminiſh it. All that ſhould be avoided here is the intolerable abſurdity of making our reaſons and ends, in acting, the phyſical cauſes or efficients of action. This is the ſame with aſcribing the action of walking, not to the feet, or the power which moves the feet, but to the eye, which only ſees the way. The perception of a reaſon for acting, or the judgment of the underſtanding, is no more than ſeeing the way; it is the eye of the mind, which informs and directs; and whatever certainty there may be, that a particular determination will follow, ſuch determination will be the ſelf-determination of the mind; and not any change of its ſtate ſtamped upon it, over which it has no power, and in receiving which, inſtead of being an agent, it is merely a paſſive ſubject of agency. Although the views and ideas of beings may be the occaſions of their acting; yet it is a contradiction to make them the mechanical efficients of their actions: ſo neceſſary and important is the diſtinction inſiſted upon by Dr. Clarke, between the operation of phyſical cauſes and the influence of moral reaſons.

Upon the whole, the queſtion concerning liberty is not, whether the views or ideas of beings influence their actions, but what is the nature of that influence. If we ſay, that it is ſome kind of mechanical or phyſical efficiency; or, with Dr. Prieſtley, after Hobbes and Leibnitz, that man has no other liberty, in following motives, than water has in running down hill, or than the arms of a ſcale, preſſed by weights, have in riſing and falling; then it muſt follow, that man never acts; and it muſt be folly to applaud or reproach ourſelves for our conduct; and there is an end of all moral obligation and accountableneſs.

However the Neceſſarians do not allow theſe conſequences; but, on the contrary, maintain, that the doctrine of the neceſſary influence of motives upon the mind of man, makes him the proper ſubject of diſcipline, reward, and puniſhment, praiſe and blame, both in the common and philoſophical uſe of the words; and that the doctrine of ſelf-determination, independently of the influence of motives, entirely diſqualifies a man from being the proper ſubject of them.

Mr. Edwards, an acute writer on this ſubject, has endeavoured to prove, that liberty of indifference is not only not neceſſary to virtue, but utterly inconſiſtent with it; and that all habits and inclinations, whether virtuous or vicious, are inconſiſtent with the Arminian notions of liberty and moral agency. And Dr. Prieſtley obſerves, that the ſenſe of ſelf-reproach and ſhame is excited by our finding that we have a diſpoſition of mind leading to vice, and on which motives to virtue, in particular caſes, have had no influence. If we aſk, whence proceeds that diſpoſition, and how it comes to paſs, that motives to virtue had not a greater influence, we muſt ultimately aſcribe the ineffiacy of the one, and the evil tendency of the other to God, who made us what we are, and placed us in the ſituation which we occupy. Dr. Prieſtley overcomes this difficulty by alledging, that the diſtinction between things natural and moral entirely ceaſes in the ſcheme of *neceſſity*; that the vices of men come under the claſs of common evils, producing miſery for a time, but, like all other evils, in the ſame great ſyſtem, ultimately ſubſervient to greater good. In this light, he ſays, every thing without diſtinction may be aſcribed to God. However, he acknowledges, that this is a view of moral evil, which, though innocent and even uſeful in ſpeculation, no wiſe man can or would chuſe to act upon himſelf, becauſe our underſtandings are too limited for the application of ſuch a means of good; though a being of infinite knowledge may introduce it with the greateſt advantage. If there be any foundation for the doctrine of *neceſſity*, i. e. if all events ariſe from preceding ſituations, and the original ſituations of all things, together with the laws by which all changes of ſituation take place, were fixed by the Divine Being, there can be no difference whatever, with reſpect to his cauſation of one thing more than another, and even whatever takes place in conſequence of his withholding his ſpecial and extraordinary influence, is as much agreeable to his will as what comes to paſs in conſequence of the general laws of nature. But our ſuppoſing that God is the author of ſin (as by the ſcheme of *neceſſity* he muſt in fact be the author of all things), by no means implies, that he is a ſinful being; for it is the diſpoſition of mind, and the deſign which conſtitute the ſinfulneſs of an action. If, therefore, his diſpoſition and deſign be good, what he does is morally good. To the ſame purpoſe he obſerves, that the proper foundation, or rather the ultimate object of virtue is general utility; ſince it conſiſts of ſuch conduct as tends to make intelligent creatures the moſt truly happy in the whole of their exiſtence; though, with reſpect to the agent, no action is denominated virtuous, that is not voluntary, or that does not proceed from ſome good motive. And this reaſoning he applies to the Deity, who purſues the happineſs of his creatures by ſuch means as are beſt calculated to ſecure that end, and which are ſanctified by it. And he farther adds, that the Deity may adopt ſome things, which he would not have choſen on their own account, but for the ſake of other things, with which they were neceſſarily connected.

The ſcriptures, according to this laſt writer, are favourable to the doctrine of *neceſſity*: though he does not think, that the ſacred writers were, ſtrictly ſpeaking, Neceſſarians, for they were not philoſophers: but their habitual devotion led them to refer all things to God, without reflecting on the rigorous meaning of their language: and very probably, had they been interrogated on the ſubject, they would have appeared not to be apprized of the proper extent of the Neceſſarian ſcheme, and would have anſwered in a manner unfavourable to it.

The reader, who is desirous of being farther acquainted with the reasoning of different writers on this subject, may consult the Collection of Papers between Leibnitz and Clarke, 1717. NECK, a part in the human body, and in that of several other animals, between the head and the thorax, or trunk of the body. See *Tab. Anat. (Osteol.) fig.* 3. *n.* 1. 1. *fig.* 7. *n.* 14. 14.

All animals have *necks*, which have lungs and voice, excepting frogs, and one class of fishes, whose characteristic it is, vocem aliquam emittere.

The upper part before it is called the *throat*; and the lower part the *pomum Adami*. The hole between the two clavicles is called the *jugulum*, by the Greeks σφαγη, *murder*; it being very easy to kill in this part. The hind part of the *neck* is called *cervix*; and the hole between the first and second vertebra, the *nape*; and that underneath, *epomis*.

Its lateral parts commence from the bottom of the ears, and are called *parotides*.

The inner parts of the *neck* are seven vertebræ, the trachea, larynx, pharynx, part of the œsophagus, jugular, cervical, and vertebral veins, carotid, vertebral, and cervical arteries, the intercostal nerve, the eighth, ninth, and tenth pair, the seven cervical pairs, the greater sympathetic nerves, the portio dura of the auditory nerves, and several muscles. See each part under its proper article.

NECK, *Derby*. See BRONCHOCELE.

NECK, *fracture of the*. The processus dentatus of the second vertebra is tied to the skull by a ligament, and kept close to the fore part of the first vertebra by another in that vertebra, that it may not bruise the spinal marrow: when either this ligament or process is broken, it makes that sort of fractured *neck*, whose consequence is sudden death.

NECK, *luxation of the*. A luxation between the head and upper vertebra is immediate death, on account of the pressure on the medulla oblongata, or medulla spinalis. But the *neck* is generally dislocated partially, in which case it swells, the countenance is bloated, the chin lies upon the breast, and the face is usually turned towards one side. To reduce this luxation, the patient is to be immediately laid flat on the ground or floor, then the surgeon, laying hold of his head, is to extend it strongly, gently moving it from side to side, till he finds that the *neck* is restored to its natural posture. Mr. Petit mentions another method by means of slings; but Heister gives the preference to the former method, both as being more simple, and because the patient can be relieved much sooner.

NECK, *wry*, a deformity, usually brought into the world with people; but sometimes occasioned by accidents afterwards. When it is from the birth, there is very little reason to expect relief, because the vertebræ of the *neck* are rendered crooked by that posture, while the bones are in a soft and pliable state. There are, however, in the writings of surgeons, some instances of this disorder, even in these circumstances, being cured after twelve, fifteen, or eighteen years.

When this disorder comes on adults, it is occasioned generally either by the contraction of the skin from a burn on one side, or from a strong spasmodic contraction of one of the mastoide muscles, which will at length become shorter and indurated, by continuing in that posture; or it may proceed from a relaxation of one or more of those muscles, in consequence of which the *neck* will be contracted by the stronger antagonist muscle, on the opposite side; or lastly, it may proceed from a preternatural ligament drawing down the head. And when either of these is the occasion of the disorder, there is hope of a cure; especially if the patient be young, and if this disorder be not of long standing.

If this disorder be recent, and caused by a defluxion of humours, evacuating medicines, with mild sudorifics, and heat, may be of service: but when it arises from a contraction of the skin or muscles, by burning, the repeated use of oils, ointment, and fomentations, may relax so far as to make a cure; a proper firm bandage must likewise be applied to pull the head toward the natural posture, and a steel collar may be contrived, by which the patient shall be suspended very frequently till the *neck* recover its proper position: but when all these fail, the manual assistance of the surgeon is to be called in. If the skin is contracted by a burn, it must be carefully incided transversely in several places, and the incisions dressed so as to keep them open and dilated, and the head pulled to its proper position by a bandage, till the new flesh, filling up these incisions, gives room for the head to stand even: but if the *wry neck* proceeds from a contraction of one of the mastoide muscles, or from some ligament, they are to be divided by a transverse incision in their lower part, near the clavicle or sternum.

NECK, *wounds of the*. There are several sorts of wounds in the *neck*; sometimes the seat of the wound is only in the common integuments, and muscular flesh; this is attended with very little danger: but the most dangerous, and indeed generally incurable wounds, are those of the larger blood-vessels in these parts: such are those of the jugular veins, and carotid and vertebral arteries; or where the aspera arteria is wounded, or the gula, the medulla spinalis, the nerves that descend by the *neck*, or when several of these parts are wounded at the same time.

Wounds of the arteries of the *neck* are scarce ever to be remedied. The patient usually bleeds to death, before a surgeon can be had in these cases; but even if a surgeon were present at the instant the wound was inflicted, the largeness of the arteries, their vicinity to the heart, and the impossibility of making a sufficient pressure upon the wounded vessel, in this part, give but little hope of relief.

Wounds in the external jugular veins are not of great danger, if a surgeon be applied to in time; but wounds in the internal jugulars are very dangerous, partly from their size, which is of the thickness of one's finger, and partly from their situation, which is so deep that no proper application can reach them to any advantage.—Wounds in this vein are usually esteemed mortal, but it is sometimes possible to save life in this case.

Wounds of the aspera arteria, or windpipe, are usually deemed mortal, where the windpipe is entirely divided, or is wounded in its lower part, within the cavity of the thorax, or joined with a wound of the carotid arteries, or internal jugulars, which is frequently the case; but if the windpipe is only wounded in its fore part, and the neighbouring vessels remain unhurt, it is usually found curable.

Wounds of the gula, or œsophagus, afford very little hopes of recovery, where it is much wounded, or entirely divided, because, in this case, not only the office of deglutition is cut off, but the part is so situated, that it is impossible almost to wound it, without injuring, at the same time, some of the neighbouring nerves, and blood-vessels: but when the gula only is wounded, and the wound small, there is some hope of recovery.

Wounds in the medulla spinalis, in one part, are very dangerous, but more particularly so when inflicted on that part of it which presses through the *neck*. It is no wonder, therefore, that scarce any recover after a considerable wound of this kind; which it is impossible should happen without wounding the vertebral veins and arteries at the same time; and the situation of the part is such, that it is impossible to convey proper remedies to them. Nor are wounds of the large nerves of the *neck* less dangerous than these; for, if they are divided, the parts of the thorax and abdomen, to which nature has determined them, immediately lose their assistance, and of consequence become unequal to the offices for which they were intended.

For the cure of wounds in the *neck*, the method is as different as the nature of those wounds. Where the integuments and muscular flesh alone are wounded, the common method of curing slight wounds takes place. Where the external jugular is hurt, the same methods used after bleeding in that vein prove sufficient. When the internal jugular has received a small wound, the hæmorrhage will be easily stopped by filling the wound well with dry lint; or with the puff ball, or dusty mushroom, lodging, over these applications, square bolsters, and securing all with a bandage, drawn as tight as the nature of the part will admit: where this method does not take place, the surgeon should make a proper pressure on the wounded part with his finger, till the hæmorrhage is entirely stopped. The same methods must be used to the wounds of the vertebral veins; and when the hæmorrhage is once stopped, the dressings applied are not to be removed for three days, and then a vulnerary balsam and plaister applied to heal the wound.

In large wounds, or an entire division of the internal jugular, the surgeon, if present in time, should make a firm pressure with his finger, on the wounded part, and make incisions lengthways, above the wound, till he can get at the vessel, and then make a firm ligature upon it, by means of a crooked needle.

In case of a wound of the carotid artery, a surgeon, if present in time, should use the same method as in those of the internal jugular vein. This method is more

likely

likely to have ſucceſs in wounds of the upper and middle part of that veſſel, than in thoſe of the lower part of it; and where the wound is not in the trunk of the artery, but in one of its branches near the head, you ſhould fill up the wound with lint dipt in ſome ſtyptic liquor, and then cover it up with thick compreſſes, ſecuring all with a tight bandage, and ordering an aſſiſtant to make a preſſure upon the part with his hand, for ſome time after: and, in theſe caſes, the dreſſings are not to be removed till the third or fourth day.

In curing the wounds of the aſpera arteria, the ſurgeon ought to clean the wound, and then endeavour to unite the parts by the help of ſticking plaſters; or, where the wound is large, by making two ſtitches with a crooked needle, drawing up the wound afterwards in the uſual manner, and enjoining the patient to keep his head in a proper ſituation, that is, ſomewhat bending downwards. The wound, thus treated, if it has been made either by puncture, or by the cutting of a ſharp inſtrument, will eaſily heal; but if it has been made by a bullet, and any part of the aſpera arteria is carried away, the future is to no purpoſe; wounds of this kind are only to be dreſſed with the vulnerary balſams. If the aſpera arteria is entirely divided, and the lower end of it has ſhrunk into the cavity of the thorax, ſo that it cannot be laid hold on, there can be no remedy.

When the œſophagus is wounded, what is taken in at the mouth comes out through the wound, and the patient is uſually affected with hiccoughs and vomitings. Where this is entirely divided, there is no remedy; but where it is only perforated or wounded in part, the cure may be attempted by dreſſing it with the vulnerary balſams, endeavouring to unite it by means of ſticking plaſters, and enjoining the patient a ſtrict abſtinence for ſome days, and giving nouriſhing glyſters of broth, milk, &c. If nouriſhment muſt be taken at length by the mouth, the wound muſt be perfectly cleaned every time afterwards, and be dreſſed daily till it heals. Wounds of the medulla ſpinalis are beſt dreſſed with balſam of Peru, or medicines of a like nature, mixed with a ſmall quantity of honey of roſes, and ſpread upon pledgits, and applied moderately warm. Slight wounds of this kind are ſometimes healed by this means; but large ones in this part always bring on certain death. Heiſter's Surg. p. 84.

In the Memoirs de l'Acad. Royale des Sciences, ann. 1730. we have ſome curious obſervations, by Mr. Winſlow, on the motions of the *neck*, and alſo on thoſe of the head and ſpine.

NECK, *the, of quadrupeds*, Dr. Derham obſerves, are always equal to the length of their legs: this is contrived by nature, to enable them to reach the ground for their food, without ſtooping the body.

Indeed, the elephant is an exception from the rule: its *neck* is very ſhort; but then it has a peculiar proviſion by a proboſcis, or trunk.

Another thing remarkable in the *necks* of graminivorous quadrupeds is a ſtrong, tendinous, and inſenſible aponeuroſis, or ligament, braced from the head to the middle of the back; by means whereof they are enabled conſtantly to hold down the head, though very heavy, to gather their food without pain or labour.

NECKS, *the, of birds* are longer than thoſe of any other animals; and longer in ſuch as have long legs than in thoſe that have ſhort, either for gathering up their meat from the ground, or ſtriking their prey in the water, except in web-footed fowl, which are, by reverſing their bodies, deſtined to ſearch for food, at the bottom of waters: birds, eſpecially thoſe that have long *necks* have the power of retracting, bending, or ſtretching them out, in order to change their center of gravity, from their legs to their wings.

NECK *verſe*, the Latin ſentence, *Miſerere mihi Deus*, was thus called, becauſe the reading of it was made a teſt, by which to diſtinguiſh thoſe, who, in preſumption of law, were not qualified, in point of learning, and admiſſible to benefit of clergy: but this ground of diſtinction was ſet aſide by 5 Ann. cap. 6. See CLERGY.

NECK, in the *Manege*. See CARRYING.

NECK, *of the caſſoket*, in *Artillery*, is that part betwixt the breech mouldings and the *caſſoket*.

NECK *of a gun* is that part betwixt the muzzle mouldings and the cornice-ring.

NECKIB-*elhoſſeraf*, in Egypt, the head of the ſherif, or relations of Mahomet, who has the great cognizance of their actions, and the power of inflicting puniſhments upon them.

NECKLACE *beads*. See SNAKE.

NECOPHORON, in *Botany*, a name uſed by Pliny, and other authors, for the *ſmilax aſpera*, or *rough bindweed*.

NECROLIUM, a word uſed by ſome of the alchemical writers to expreſs a remedy almoſt always capable of averting death, and continuing life to its utmoſt period.

NECROLOGY, *necrologium*, formed of νεκρος, *dead*, and λογος, *diſcourſe* or *enumeration*, a book anciently kept in churches and monaſteries; wherein were regiſtered the benefactors to the ſame, the time of their deaths, and the days of their commemoration; as alſo the deaths of the priors, abbots, religious, canons, &c.

This was otherwiſe called *calendar* and *obituary*.

NECROMANCY, formed from νεκρος, *dead*, and μαντια, *ſoothſayment* or *divination*, the art, or act of communicating with devils, and doing ſurpriſing feats by their aſſiſtance; particularly of calling up the dead, and extorting anſwers from them. See MAGIC.

NECROSIS, νεκρωσις, in *Medicine*, a complete mortification of any part; called alſo *ſideratio*, and SPHACELUS.

NECTAR, νεκταρ, among the *Ancient Poets*, the drink of the fabulous deities of the heathens. See AMBROSIA.

NECTAR, is alſo uſed, by ſome of the ancients, to expreſs HONEY: this ſignification of the word was owing to the ſuppoſition that honey was the drink of the bees, as they eſteemed the yellow matter collected on their thighs to be their food. They called the latter ambroſia. It ſeems that the ancients have been more in the right as to their opinion of the ambroſia than other authors, who have uſually eſteemed that yellow ſubſtance to be true wax: but it appears from experiments, that it is not really ſo; nor can wax be ſeparated from it by any of the known proceſſes of chemiſtry. It ſeems rather that the bees eat it, agreeably to the opinion of the ancients, and that after having ſerved them as nouriſhment, it is converted in the bowels into the ſubſtance we call wax.

NECTARINE, a fruit greatly eſteemed for its delicious flavour, and ſuppoſed to have its name from the nectar of the Gods, in heathen ſtories.

It differs in nothing from the peach, but in having a ſmoother ſkin and a firmer pulp.

We have ten kinds of *nectarine* cultivated by the curious in gardening; viz. Fairchild's early *nectarine*, ripening in the end of July; the Ebruge, Newington, ſcarlet, Brugnon or Italian, and Roman, which ripen in Auguſt; the murry, golden, and Temple's, which ripen in September; and the Peterborough, or late green *nectarine*, which ripens about the middle of October.

The inſects in *nectarines* may be deſtroyed in the ſame manner as thoſe of PEACH *trees*.

The pruning, planting, and whole culture of this plant, are the ſame with that of the PEACH.

NECTARIUM, among *Botaniſts*, expreſſes what is only a part of the corolla, ſometimes, though more rarely the whole. It is a part deſtined for the reception of the honey juice of the plant; and is very various in its figure. Sometimes, it is only a hollow in a petal; ſometimes it is a little ſquamma; ſometimes a tubercle; and ſometimes a plain tube.

NECUIA, in *Botany*, a name given by the ancient Greeks to a ſpecies of MULLEIN.

The Greeks and Romans both uſed the ſtalks of a peculiar kind of *mullein*, called *thryallis* by Nicander. For the making of wicks of lamps, we have a kind of *mullein*, called *lychnites*, and candlewick *mullein*, from the λυχνιτις of Dioſcorides; but it is not certain that our's is the ſame plant.

The ancients uſed the ſtalks of many different plants for the wicks of their candles and lamps. The ruſh, ſtripped of its bark, was as commonly in uſe with them as with us for this purpoſe; and they alſo uſed the nettle, this *mullein*, and many other plants, whoſe ſtalks were compoſed of tough filaments, for the ſame purpoſe; beating them out like hemp, and when dry, dipping them in melted reſin, and other ſuch inflammable ſubſtances. When thus prepared, they are readily inflammable, like our flambeaux, and this *mullein*, having ſtalks more long and large, and more firm than all the others, was uſed to make thoſe lights with which they ſet fire to the funeral pile for conſuming the aſhes of their dead friends.

NECYDALIS, in the *Linnæan Syſtem*, is a genus of the *coleoptera* order of *inſects*, diſtinguiſhed by having the antennæ ſetaceous, the exterior wings, ſmaller, ſhorter, and narrower than the interior, and a ſimple tail. There are eleven ſpecies.

NEEDLE, a very common little inſtrument, or uteníil, made of ſteel, pointed at one end, and pierced at the other; uſed in ſewing, embroidery, tapeſtry-work, &c.

Needles make a very conſiderable article in commerce; and the conſumption thereof is almoſt incredible. The ſizes are from N° 1, the largeſt, to N° 25, the ſmalleſt. There is ſcarce any commodity cheaper than *needles*;

which will appear ſomething extraordinary to the reader, after he has been ſhewn the great number of operations they undergo, before they are brought to perfection.

NEEDLES, *manufacture of.* German and Hungarian ſteel is of moſt repute for *needles*. The firſt thing is to paſs it through a coal fire, and under a hammer, and to bring it out of its ſquare figure into a cylindrical one: this done, it is drawn through a large hole of a wire-drawing iron; returned into the fire, and drawn through a ſecond hole of the iron, ſmaller than the firſt; and thus ſucceſſively from hole to hole, till it has acquired the degree of fineneſs required for that ſpecies of *needles*; obſerving every time it is to be drawn, that it be greaſed over with lard, to render it the more manageable. The ſteel, thus reduced into a fine wire, is cut in pieces of the length of the *needles* intended. Theſe pieces are flatted at one end, on the anvil, in order to form the head and eye: they are then put into the fire, to ſoften them farther; and thence taken out and pierced at each extreme of the flat part, on the anvil, by the force of a puncheon of well-tempered ſteel, and laid on a leaden block, to bring out, with another puncheon, the little piece of ſteel remaining in the eye.

The corners are then filed off the ſquare of the heads, and a little cavity filed on each ſide the flat of the head. This done, the point is formed with a file; and the whole filed over.

They are then laid to heat red-hot, on a long, flat, narrow iron, crooked at one end, in a charcoal fire; and, when taken out thence, are thrown into a baſon of cold water to harden. On this operation a good deal depends; too much heat burns them, and too little leaves them ſoft; the medium is only to be learnt by experience.

When they are thus hardened, they are laid in an iron ſhovel, on a fire more or leſs brisk, in proportion to the thickneſs of the *needles*; taking care to move them from time to time. This ſerves to temper them, and take off their brittleneſs; great care, here too, muſt be taken of the degree of heat. They are then ſtraitened, one after another, with the hammer; the coldneſs of the water, uſed in hardening them, having twiſted the greateſt part of them.

The next proceſs is the poliſhing. To do this, they take twelve or fifteen thouſand *needles*, and range them in little heaps againſt each other, on a piece of new-buckram, ſprinkled with emery-duſt. The *needles*, thus diſpoſed, emery-duſt is thrown over them, which is again ſprinkled with oil of olives: at laſt, the whole is made up into a roll, well bound at both ends.

This roll is then laid on a poliſhing-table, and over it a thick plank, loaded with ſtones, which two men work backwards and forwards, a day and half, or two days ſucceſſively: by which means, the roll, thus continually agitated by the weight and motion of the plank over it, the *needles* within-ſide, being rubbed againſt each other, with oil and emery, are inſenſibly poliſhed.

In Germany, inſtead of hands, they poliſh with water-mills.

After poliſhing, they are taken out, and the filth waſhed off them, with hot water and ſoap: they are then wiped in hot bran, a little moiſtened, placed, with the *needles*, in a round box, ſuſpended in the air by a cord, which is kept ſtirring till the bran and *needles* be dry.

The *needles*, thus wiped in two or three different brans, are taken out, and put in wooden veſſels, to have the good ſeparated from thoſe, whoſe points or eyes have been broken, either in poliſhing or wiping: the points are then all turned the ſame way, and ſmoothed with an emery-ſtone, turned with a wheel.

This operation finiſhes them; and there remains nothing but to make them into packets of two hundred and fifty each.

NEEDLES, *ſurgeons*, are generally made crooked, and their points triangular: however they are of different forms and ſizes, and bear different names, according to the purpoſes they are uſed for.

The largeſt are *needles for amputation*; the next, *needles for wounds*; the fineſt, *needles for ſutures*. They have others, very ſhort and flat, for tendons; others, ſtill ſhorter, and the eye placed in the middle, for tying together of veſſels, &c. See *Tab. Surgery, fig.* 11 and 12.

Needles for couching CATARACTS are of various kinds; all of which have a ſmall, broad, and ſharp point or tongue; and ſome with a ſulcus at the point. Surgeons have ſometimes uſed two *needles* in this operation, one with a ſharp point for perforating the coats of the eye, and another with a more obtuſe point for depreſſing or couching the opake cryſtalline lens: but care ſhould be taken in the uſe of any of theſe, that they be firſt well poliſhed, with cloth or leather, before they are applied to the eye.

Mr. Warner obſerves, that the blade of the couching *needle* ſhould be at leaſt a third part larger than thoſe generally uſed upon this occaſion, as great advantages will be found in the depreſſing of the cataract, by the increaſed breadth of the blade of that inſtrument. The handle, alſo, if made ſomewhat ſhorter than uſual, will enable the operator to perform with greater ſteadineſs, than he can do with a larger handled inſtrument. See *Tab. III. Surgery, fig.* 33.

It is to be obſerved, that *needles* of ſilver pierce more eaſily in ſtitching arteries after an amputation, than thoſe made of ſteel. Monro. in Med. Eſſ. Edinb. vol. v. art. 41.

NEEDLE, *magnetical*, in *Navigation*, denotes a *needle* touched with a loadſtone, and ſuſtained on a pivot or center, on which, playing at liberty, it directs itſelf to certain points in or under the horizon. See MAGNET.

Magnetical *needles* are of two kinds; viz. *horizontal* and *inclinatory*.

NEEDLES, *horizontal*, are thoſe equally balanced on each ſide the pivot which ſuſtains them; and which, playing horizontally, with their two extremes point out the north and ſouth points of the horizon. For their application and uſe, ſee COMPASS.

NEEDLE, *conſtruction of an horizontal*. A piece of pure ſteel is procured, of a length not exceeding ſix inches, leſt its weight impede its volubility; very thin, to take its verticity the better; and not pierced with any holes, or the like, for ornament ſake, which prevent the equable diffuſion of the magnetic virtue.

A perforation is then made in the middle of its length, and a braſs cap or head ſoldered on, whoſe inner cavity is conical, ſo as to play freely on the ſtyle or pivot, headed with a fine ſteel point.

The north point of the *needle*, in our hemiſphere, is made a little lighter than the ſouthern, the touch always deſtroying the balance, if well adjuſted before; and rendering the north end heavier than the ſouth, and thus occaſioning the *needle* to dip.

Now to give the *needle* its verticity, or directive faculty, it is to be rubbed leiſurely on each pole of a magnet, from the ſouth pole towards the north; firſt beginning with the northern end, and going back at each repeated rub toward the ſouth. A rub in a contrary direction takes away the power communicated by the former.

Compaſs *needles* may acquire the magnetic virtue by means of magnetic bars in the following manner: lay two *needles* of equal length, about an inch aſunder, with the north end of one and the ſouth end of the other pointing the ſame way, and apply two conductors in contact with their ends: then, with two magnetic hard bars, one in each hand, and held as nearly horizontal as can be, with the upper ends, of contrary names, turned outwards to the right and left, let a *needle* be ſtroked or rubbed from the middle to both ends at the ſame time, for ten or twelve times, a north end of a bar going over the ſouth end of the *needle*, and the ſouth end of a bar going over the north end of a *needle*: then, without moving from the place, change hands with the bars, or, in the ſame hands, turn the other ends downwards, and ſtroke the other *needle* in like manner, and they will both be magnetical: but to make them ſtill ſtronger, repeat the operation three or four times from *needle* to *needle*; and at laſt turn the lower ſide of each *needle* upwards, and repeat the operations of rubbing them, as on the other ſides.

In the rubbings or touchings to procure magnetiſm, the hand ſhould not return directly back the way it came, but ſhould return in a kind of oval figure, carrying the hand about ſix or eight inches beyond the point, where the touch ended; but not beyond, on the ſide where the touch begins.

If, after touching, the *needle* be out of its equilibrium, ſomething muſt be filed off from the heavier ſide, till it balance evenly.

The *needles*, that were formerly applied to compaſſes, on board our merchant ſhips, were formed of two pieces of ſteel wire; each of which was bent in the middle, ſo as to make an obtuſe angle; and their ends being applied together made an acute one; ſo that the whole repreſents the form of a lozenge. Dr. Knight, to whom we are indebted for the improvement of the compaſs, found, by repeated experiments, that theſe *needles* not only varied from the true direction, but from one another, and from themſelves: and he has ſhewn that theſe irregularities were owing to their ſtructure: for the wires of which the *needle* was compoſed were hardened only at their ends; now if thoſe ends are not equally hard, or if one end be hardened higher up than the other, when they come to be put together, in fixing them to the card, that end which is hardeſt will deſtroy much of the virtue of the other; by which means the hardeſt end will have the greateſt power in directing the card, and conſequently

make

make it vary towards its own direction: and as the wires are diſpoſed in the form of a lozenge, theſe cards can have but little force: ſo that they will often, when drawn aſide, ſtand at the diſtance of ſeveral degrees on either ſide the point from whence they are drawn; for all magnetical bodies receive an additional ſtrength by being placed in the direction of the earth's magneriſm, and act proportionably with leſs vigour when turned out of it. Therefore, when *needles* of this kind are drawn aſide from their true point, two of the parallel ſides of the lozenge will conſpire more directly than before with the earth's magneriſm, and the other two leſs in that direction: by this means the two former ſides will very much impede its return, and the two latter will have that impediment to overcome, as well as the friction, by their own force alone.

The *needles* formerly uſed on board the men of war, and ſome of the larger trading ſhips, were made of one piece of ſteel, of a ſpring temper, and broad towards the ends, but tapering towards the middle. Every *needle* of this form is found to have ſix poles inſtead of two, one at each end, two where it becomes tapering, and two at the hole in the middle. This inconvenience is owing to their ſhape; for the middle part, being very ſlender, has not ſubſtance enough to conduct the magnetic ſtream quite through from one end to the other. In order to avoid theſe inconveniences and errors, the *needle*, contrived by Dr. Knight, for his compaſs, is quite ſtrait and ſquare at the ends, and conſequently has only two poles, although the curves are a little confuſed about the hole in the middle. *Needles* of this conſtruction, after vibrating a long time, will always point exactly in the ſame direction; and if drawn ever ſo little on one ſide, will return to it again, without any ſenſible difference. Hence, Dr. Knight concludes, that a regular parallelopiped is the beſt ſhape for a *needle*, as well as the ſimpleſt; with the holes for the caps as ſmall as can be well contrived; or if it can be made to anſwer the purpoſe, without any hole at all, it will be ſtill more perfect.—There is a peculiar advantage attending Dr. Knight's *needles*; for as they are tempered much higher than uſual, they are able to contain a much greater quantity of the magnetic force. See COMPASS.

Mr. Michell ſuggeſts, that it would not be amiſs to cover the *needles*, made uſe of in the ſea-ſervice, with a very thin coat of ſinfeed oil, or ſome kind of varniſh, that may keep them from ruſting, which is generally reckoned to injure all magnetical bodies, that are liable to it. *Needles* may be touched through ſuch a coat, by applying a great number of bars, if not according to the common method of making MAGNETS. He alſo apprehends, that coated *needles* may retain a greater degree of magnetiſm, than they otherwiſe would do.

Mr. Michell alſo propoſes to increaſe the weight and length of mariners *needles*; and he obſerves, that long *needles*, properly hung, traverſing to a greater degree of exactneſs than the ſhort ones, may be of conſiderable ſervice on many occaſions: particularly in mines for diſcovering the bearing of one place from another, that they may be able to ſink a ſhaft from above, over any place at pleaſure. In many ſorts of mines, eſpecially thoſe of coal, there are often ſmall quantities of magnetical iron ore, which draw the *needle* out of its proper direction: now the long *needles* are leſs liable to be diſturbed by any ſmall things, already magnetical, than ſhorter ones. Michell on Magnets, p. 42, &c.

A *needle*, on occaſion, may be prepared without touching it on a loadſtone: for a fine ſteel *needle*, gently laid on the water, or delicately ſuſpended in the air, will direct itſelf to the north and ſouth.

Thus alſo a *needle*, heated in the fire, and cooled again in the direction of the meridian, or even only in an erect ſituation, acquires the ſame faculty.

The *needle* is not found to point preciſely to the north, except in very few places; but deviates from it, more or leſs, in different places, and that too at different times; which deviation is called the *declination*.

NEEDLE, *declination of the*, is the VARIATION of the horizontal *needle* from the meridian; or the angle it makes with the meridian, when freely ſuſpended in an horizontal plane.

NEEDLES, *Cleopatra's*. See PORPHYRY.

NEEDLES, *inclinatory*, or *dipping*. See DIPPING *needle*.

NEEDLE *fiſh*, the Engliſh name of the SYNGNATHUS, with the middle of the body hexangular, and the tail pinnated.

It is the ſame fiſh with the ACUS *Ariſtotelis ſpecies altera major*.

NEEDLE *ſhell*, the Engliſh name of a ſpecies of CENTRONIA, or ECHINODERMA.

NEEDLE *ſhell* is alſo the Engliſh name of a ſpecies of TURBO, which is ſlender, and has ventricoſe ſpires, and a ſmall mouth.

NEEDLES, *touch*. See TOUCH *needles*.

NEEDLE, *ſhepherd's*, the name by which ſome writers call the *ſcandix*, or *Venus's comb*. See SHEPHERD'S *needle*.

NE EXEAT REGNO, in *Law*, is a writ to reſtrain a perſon from going out of the kingdom, without the king's licence. F. N. B. 85. It may be directed to the ſheriff, to make the party find ſurety that he will not depart the realm: and on refuſal, to commit him to priſon: or it may be directed to the party himſelf; and if he then goes, he may be fined. 3 Inſt. 178. And this writ is granted on a ſuit being commenced againſt a man in the chancery, when the plaintiff fears the defendant will fly to ſome other country; and thereby avoid the juſtice and equity of the court; which hath been ſometimes practiſed: and when thus granted, the party muſt give bonds to the maſter of the rolls, in the penalty of 1000 l. or ſome other large ſum, for yielding obedience to it; or ſatisfy the court, by anſwer, affidavit, or otherwiſe, that he hath no deſign of leaving the kingdom, and give ſecurity.

NEEP *tides*. See NEAP *tides*.

NEFASTUS, a Latin term. The Romans uſed the appellation, *dies nefaſti*, for thoſe days wherein it was not allowed to adminiſter juſtice, or hold courts; nor for the prætor to pronounce the three ſolemn words or formulas of the law, *Do, dico, addico, I give, I appoint, I adjudge*. See FASTI.

Theſe days were diſtinguiſhed in the calendar by the letter, N. or by N. P. *nefaſtus primo*, as when the day was only *nefaſtus* for the firſt part thereof.

NEGATION, in *Logic*, an act whereby the mind ſeparates one idea from another; or affirms the one to be different from the other: as the ſoul is not matter.

NEGATION is alſo applied by logicians to not-being, as it has relation to modes, and denotes the abſence of that which does not naturally belong to the thing ſpoken of, or which has no right, obligation, or neceſſity to be preſent with it. In this ſenſe it is oppoſed to PRIVATION, and was denominated in the ſchools *abſentia habitus*.

NEGATIVE, a term that denies, or implies a denial of any thing.

Logicians, &c. ſay, a *negative* cannot be proved but by converting it into an affirmative.

NEGATIVE *heretics*, in the language of the inquiſition, are thoſe, who, being accuſed of hereſy, by witneſſes whoſe evidence they do not deny, ſtill keep on the *negative*, make open profeſſion of the catholic doctrine, and declare their abhorrence of hereſy.

There are alſo *negative ſchiſms*, as well as poſitive ones.—In the *negative*, it is ſufficient to reject the errors of a church without ſeparating from it, or ſetting up a diſtinct ſociety.

NEGATIVE *penalties*, the laws whereby certain perſons are excluded from honours, dignities, &c. without inflicting any direct and poſitive pains on them.

NEGATIVE *power*, in *Algebra*. See POWER.

NEGATIVE *pregnant*, in *Law*, a *negative* which implies or brings forth an affirmative.

As if a man, being impleaded to have done a thing on ſuch a day, in ſuch a place, denies he did it, *modo & forma declarata*; which implies, nevertheleſs, that he did it in ſome ſort.

NEGATIVE *quantity*, in *Algebra*. See QUANTITY.

NEGATIVE *ſign*. The uſe of the *negative ſign*, in *Algebra*, is attended with ſeveral conſequences that at firſt ſight are admitted with difficulty, and has ſometimes given occaſion to notions that ſeem to have no real foundation. This ſign implies that the real value of the quantity repreſented by the letter to which it is prefixed, is to be ſubtracted; and it ſerves, with the poſitive ſign, to keep in view what elements or parts enter into the compoſition of quantities, and in what manner, whether as increments or decrements (that is, whether by addition or ſubtraction), which is of the greateſt uſe in this art.

In conſequence of this, it ſerves to expreſs a quantity of an oppoſite quality to the poſitive, as a line in a contrary poſition; a motion with an oppoſite direction; or a centrifugal force in oppoſition to gravity; and thus often ſaves the trouble of diſtinguiſhing, and demonſtrating ſeparately, the various caſes of proportions, and preſerves their analogy in view. But as the proportions of lines depend on their magnitude only, without regard to their poſition; and motions and forces are ſaid to be equal, or unequal, in any given ratio, without regard to their directions; and, in general, the proportion of quantity relates to their magnitude only, without determining whether they are to be conſidered as increments or decrements; ſo there is no ground to imagine any other proportion of $-b$ and $+a$ (or of -1 and 1) than that of the real magnitudes of the quantities repreſented by b and a, whether theſe quantities are, in any particular caſe, to be added or ſubtracted. It is the ſame thing to ſubtract a decrement as to add an equal increment

ment, or to subtract $-b$ from $a-b$, as to add $+b$ to it: and because multiplying a quantity by a *negative* number implies only a repeated subtraction of it, the multiplying $-b$ by $-n$, is subtracting $-b$ as often as there are units in n; and is therefore equivalent to adding $+b$ so many times, or the same as adding $+nb$. But if we infer from this, that 1 is to $-n$ as $-b$ to nb, according to the rule, that unit is to one of the factors as the other factor is to the product, there is no ground to imagine that there is any mystery in this, or any other meaning than that the real magnitudes represented by 1, n, b, and nb are proportional. For that rule relates only to the magnitude of the factors and product, without determining whether any factor, or the product, is to be added, or subtracted. But this likewise must be determined in algebraic computations; and this is the proper use of the rules concerning the signs, without which the operation could not proceed. Because a quantity to be subtracted is never produced in composition, by any repeated addition of a positive, or repeated subtraction of a *negative*, a *negative* square number is never produced by composition from the root. Hence $\sqrt{-1}$, or the square root of a *negative*, implies an imaginary quantity; and, in resolution, is a mark or character of the impossible cases of a problem, unless it is compensated by another imaginary symbol, or supposition, when the whole expression may have a real signification. Thus $1+\sqrt{-1}$, and $1-\sqrt{-1}$ taken separately, are imaginary, but their sum is 2; as the conditions that separately would render the solution of a problem impossible, in some cases destroy each other's effect, when conjoined. In the pursuit of general conclusions, and of simple forms representing them, expressions of this kind must sometimes arise where the imaginary symbol is compensated in a manner that is not always so obvious.

By proper substitutions, however, the expression may be transformed into another, wherein each particular term may have a real signification as well as the whole expression. The theorems that are sometimes briefly discovered by the use of this symbol, may be demonstrated without it, by the inverse operation, or some other way; and though such symbols are of some use in the computations by the method of fluxions, its evidence cannot be said to depend upon arts of this kind. See Maclaurin's Fluxions, book ii. chap. 1.

NEGATIVELY, NEGATIVE, in the school philosophy, is variously used in contradistinction to positive. See POSITIVE.

NEGROES, a kind of black slaves, which make a considerable article in the modern commerce.

The *Negroes*, also called *Blacks* and *Moors*, are a people of Africa, whose country extends on each side of the river *Niger*, and is called *Nigritia*: though, whether the people communicated their name to the river, &c. or received it therefrom, is not easily determined.

The origin of *Negroes*, and the cause of that remarkable difference in complection from the rest of mankind, has much perplexed the naturalists; nor has any thing satisfactory been yet offered on that head.

Mr. Boyle has observed, that the heat of the climates cannot be the true cause of the colour of *Negroes*: for though the heat of the sun may darken the colour of the skin, yet experience does not show that heat is sufficient to produce a true blackness, like that of *Negroes*. In Africa itself, many nations of Æthiopia are not *Negroes*, nor were there any blacks originally in the West Indies. In many parts of Asia, under the same parallel with the African regions, inhabited by blacks, the people are but tawny. He adds, that there are *Negroes* in Africa, beyond the southern tropic, and that a river sometimes parts nations, one of which is black, and the other but tawny. Boyle's Works Abr. vol. ii. p. 42. 44.

Dr. Barrere alledges that the gall of *Negroes* is black, and being mixed with their blood, is deposited between their skin, and scarf skin. Diss. on the Phys. Cause of the Colour of *Negroes*.

We have a dissertation on this head by Dr. John Mitchell, of Virginia, in the Philosophical Transactions, N° 476. sect. 4. where he advances these propositions, and enters into a learned detail to support them.

1. The colour of white people proceeds from the colour which the epidermis transmits; that is, from the colour of the parts under the epidermis, rather than from any colour of its own.

2. The skins of *Negroes* are of a thicker substance, and denser texture, than those of white people, and transmit no colour through them.

3. The part of the skin which appears black in *Negroes*, is the *corpus reticulare cutis*, and external lamella of the epidermis: all other parts are of the same colour in them with those of other people, except the fibres which pass between those two parts.

4. The colour of *Negroes* does not proceed from any black humour, or fluid parts contained in their skins; there being none such in any part of their bodies, more than in white people.

5. The epidermis, especially its external lamella, is divided into two parts by its pores and scales, two hundred times less than the particles of bodies on which their colours depend.

This is founded on Leeuwenhoek's observation, that a portion of the epidermis no bigger than what can be discerned by the naked eye, is divided into 125000 pores, and these pores must divide such a portion of the skin into as many particles. But the particles of bodies on which their colours depend, are, by Sir Isaac Newton's Optics, lib. ii. p. 3. prop. 7. 600 times less than those which can be discerned by the naked eye. Therefore, the particles of the skin must be about 200 times less than these; since $125000 \times 200 = 208^3$. It may also be observed that such a small portion of the epidermis is divisible into 250 scales, which must increase the number of its parts.

6. From these propositions, and from Sir Isaac Newton's theory of light and colours, the doctor thinks he may conclude, that the proximate cause of the colour of *Negroes* is threefold; viz. The opacity of their skin, proceeding from the thickness and density of its texture, which obstructs the transmission of the rays of light, from the white and red parts under the skin, together with its greater refractive power, which absorbs these rays; and the smallness of the particles of this skin, which hinders it from reflecting any light.

7. The influence of the sun in hot countries, and the manner of life of their inhabitants, are the remote causes of the colour of *Negroes*, Indians, &c. And the ways of living in use amongst most nations of white people, make their colours whiter than they were originally, or would be naturally.

In support of this proposition, the doctor observes, that the skin is deprived of its white colour, by the force and influence of the sun, four ways. 1st. By being rendered opaque, from a dissipation of its more aqueous, and pellucid juices. 2dly. By a concretion of its vessels and glandules, from this dissipation of their aqueous contents, which renders the skin both thicker and denser, or more callous and rigid. 3dly. By a new accretion of many new membranes, which render it thick and opaque. 4thly. By increasing those parts or principles, in the composition of the epidermis, which have the greatest refractive power; as the terrestrial and fixed saline; but especially the tenaceous sulphureous, which refract and absorb light more strongly than any other substances; while the more transparent and pellucid principles, as the aqueous, spirituous, and volatile saline, are evaporated by the heat, which causes the other more fixed principles to be accumulated; and these particles being likewise more comminuted by the sun, will, on this account, be black; as happens to oil when well boiled. These causes, with those first mentioned, may, the doctor thinks, by conspiring, make the skin quite black; especially if we add another effect of the sun's power, a peculiar necrosis of the epidermis, occasioned by the forcible vibrations, contractions, and exsiccations of its fibres by the sun-beams, which cause it to turn black, as these, or other parts do, by the heat of an inflammation, or a fever, in gangrenes, black tongues, &c.

We cannot pretend to follow the author in all the detail of his observations on this subject, nor of his answer to a material objection already mentioned from Mr. Boyle, that the sun cannot be the cause of the colour of *Negroes*, because several nations, in the same latitude with those *Negroes*, are not made black by it. He seems to think the heat of Africa greater than that of other parts of the world. Whether it be so, or not, is, we apprehend, not easy to determine; but it would be a strong confirmation of his doctrine, if we could see any people, originally white, become black and woolly by transplantation, or vice versa.

Negroes are brought from Guinea, and other coasts of Africa, and sent into the colonies in America, to cultivate sugar, tobacco, indigo, &c. and Peru and Mexico to dig in the mines.

This commerce, which is scarce defensible on the principles either of religion, or humanity, is now carried on by all the nations that have settlements in the West Indies; particularly by the English, Dutch, Spaniards, and Portuguese. See ASSIENTO.

The Spaniards, indeed, have few *Negroes* at first hand; but have treated with other nations to furnish them therewith: thus they were formerly furnished by the company of the Grilles, established at Genoa; since, by the Assiento in France; and after the peace of Utrecht, by the English South-sea company.

By the peace of Aix-la Chapelle, in 1748, the Assiento

treaty

treaty between the English and Spaniards, was abolished: but, during its continuance, the South Sea Company furnished the American dominions of Spain with four thousand eight hundred *Negroes*, who, on their arrival, were separated into four claſſes: the firſt claſs conſiſted of all in perfect health, from fifteen to thirty years of age, who were charged with a duty of 33¼ piaſtres each, or per head; the ſecond claſs was compoſed of the old and ſick, each of whom was rated at ½ of a head; the children, from ten to fifteen years old, formed the third claſs, and were reckoned at three for two heads; and thoſe from five to ten compoſed the fourth claſs, and were rated at two for one head; and the duty was paid accordingly.

There are various ways of procuring theſe *Negroes*: ſome, to avoid famine, ſell themſelves, their wives, and children; to their princes, or great men, who have wherewithal to ſubſiſt them. Others are made priſoners in war; and great numbers ſeized in excurſions made for that very purpoſe by the petty princes upon one another's territories; in which it is uſual to ſweep away all both old and young, male and female.

The *Negroes* make a frequent practice of ſurpriſing one another while the European veſſels are at anchor, and dragging thoſe they have caught to them, and ſelling them in ſpite of themſelves; and it is no extraordinary thing to ſee the ſon ſell, after this manner, his father or mother, and the father his own children, for a few bottles of brandy, or a bar of iron.

As ſoon as the ſhip has its complement, it immediately makes off; the poor wretches, while yet in ſight of their country, falling into ſuch deep grief and deſpair in the paſſage, that a great part of them languiſh, fall into ſickneſs and die: while others of them ſtarve themſelves. The only ſure means to preſerve them, is to have ſome muſical inſtrument play to them, be it ever ſo mean. But this exceſſive love for their country abates as they get farther off.

It has been calculated that upwards of one hundred thouſand ſlaves have for many years been exported by the *Europeans* from the coaſt of *Africa*.

By the laws of Virginia, *Negro* ſervants are ſaleable; and where a *Negro* is ſold here, in action *indebitat aſſumpſit*, for the money, the declaration ought to be, that the defendant was indebted to the plaintiff for the *Negro* ſold here at *London*, but the ſaid *Negro* at the time of the ſale was in Virginia, and that by the laws and ſtatutes of Virginia, *Negroes* are ſaleable as chattels. Per Holt. C. J. 2 Salk. Rep. 666. In action of trover for a *Negro*, and verdict and damages for the plaintiff, it was moved in arreſt of judgment, that trover lay not for a *Negro*, for the owner had not an abſolute property in him; but the court ſeemed to think, that in treſpaſs, *quare captivum ſuum cepit*, the plaintiff might give in evidence that the party was his *Negro*, and he bought him. Ibid. ſee ſtat. 13 Geo. I. cap. 9.

It is now laid down, that a ſlave or *Negro*, the inſtant he lands in England, becomes a freeman; that is, ſo far as that the law would protect him in the enjoyment of his perſon and property. But with regard to any right which the maſter may have acquired to the perpetual ſervice of John or Thomas, this will remain exactly in the ſame ſtate as before. Hence alſo it follows, that the infamous and unchriſtian practice of with-holding baptiſm from *Negro* ſervants, leſt they ſhould thereby gain their liberty, is totally without foundation, as well as without excuſe; for the ſlave is intitled to the ſame protection in England before, as after baptiſm, and whatever ſervice the heathen *Negro* owed to his American maſter, the ſame he is bound to render, when brought to England and made a Chriſtian. Blackſt. Com. b. 1. p. 424.

NEGRO, in *Ornithology*, the name of a large bird, approaching to the crane kind, and more uſually known among authors by its Braſilian name JABIRU.

NEGRO *oil*, in *Botany*. See PALM-*tree*.

NEHEMIAH, a canonical Book of the Old Teſtament, ſo called from the name of its author. *Nehemiah* was born at Babylon, during the captivity, and ſucceeded Ezra in the government of Judah and Jeruſalem. He was a Jew, and was promoted to the office of cup-bearer to Artaxerxes Longimanus, king of Perſia; when the opportunities he had of being daily in the king's preſence, together with the favour of Eſther, the queen, procured him liberty to repair and fortify the city of Jeruſalem, in the ſame manner as it was before its deſtruction by the Babylonians. On his going to Jeruſalem, he finiſhed the rebuilding of the walls in fifty-two days, and dedicated the gates of the city with great ſolemnity. He then reformed ſome abuſes which had crept in among his countrymen. The hiſtory of theſe tranſactions is the ſubject of this book.

NEIF, *native*, in our *Ancient Cuſtoms*, a bond woman, or ſhe villain, born in one's houſe. 9 Rich. II. cap. 2.

Anciently, lords of manors, ſold, gave, or aſſigned their *neifs*, and natives. See SLAVE, VILLAIN, &c.

NEIFTY, *writ of*, is an ancient writ, whereby the lord claimed ſuch a woman for his *neif*.

NE INJUSTE *vexes*, a writ founded on *Magna Carta*, cap. 10. which lies for a tenant in fee ſimple or fee tail, the lord, forbidding him to diſtrain on the tenant, for more ſervice than he ought to perform; particularly when he has formerly prejudiced himſelf by doing or paying more than he needed.

NELANJENUM, in *Natural Hiſtory*, the name of a curious and peculiar foſſile ſubſtance, found in the Eaſt Indies.

It has much the appearance of ſome of our ſteel-grained lead ores, and is very ponderous, but it does not contain any lead: in this it approaches to the nature of that ſubſtance common in Europe, and called blende, or mock lead; but this laſt is foliated, and reſembles the plated lead ores, whereas this reſembles the cloſe ground ores. It is found in the beds of rivers in many places; they calcine it, and, reducing it to powder, mix it with the juice of herbs, and uſe it in ulcers.

NELLA *curcuidum*, in *Natural Hiſtory*, a name given by the people of the Eaſt Indies to a very hard ſtone which they uſe as we do emery.

It is of a talcky nature, being compoſed of flaky ſpangles, and a coarſer matter interminxed. They dig it at the foot of ſome mountains, and in ſome other places. It lies ſo near the ſurface that the rice fields abound with it; and it is ſeen on ſtirring the ground. It is always found in nodules, or detached maſſes, and is uſually of a ſort of iron colour, though ſubject to ſome variations. It is uſed by the common people to ſcour arms, and other iron works; and by the lapidaries, among them, to poliſh rubies and other ſtones. For this laſt purpoſe they grind it with ſtick lac, and make it into a ſort of cement, with which they daub over the face of the poliſhing machine.

NELLON, in *Botany*, a name given by ſome to rice. It is an Indian word, and properly ſignifies the grain of rice taken off from the ſtalks, but covered with its proper pellicle. The firſt operation to be performed upon this, is the beating it with large ſtones, or other more manageable tools, till this ſkin flies off. Then it is to be dried in the ſun, and, after that bear a ſecond time, to get off its thin, internal, reddiſh coat: when this is done, it is in a ſtate to be uſed, and it is then only that the Indians call it *arriſ*, the word from which we formed our word rice.

NELUMBO, in *Botany*, the name of a genus of plants, uſually confounded with the nymphæa.

The characters of the *nelumbo* are theſe; the flower is like that of the nymphæa, but the fruit wholly different, not only in ſhape, but in ſtructure, being not divided into ſeveral cells, but having the ſeeds placed irregularly, at diſtances from one another in it.

There is only one known ſpecies of this genus, which is the *nelumbo* of the Ceyloneſe, called by others the *Indian nymphæa*, and *faba Ægyptiaca*, the *Egyptian bean*.

NEMÆAN, or NEMEAN *games*, one of the four great kinds of games, or combats, celebrated among the ancient Greeks.

Some ſay, they were inſtituted by Hercules, on occaſion of his killing the *Nemean* lion; and that it was hence they took their name, as alſo the place of celebration, the foreſt of *Nemea*.

Others relate, that the ſeven chiefs ſent to Thebes, under the conduct of Polynices, being extremely oppreſſed in their journey with thirſt, met with Hypſipyle of Lemnos, who had in her arms Opheltes, ſon of Lycurgus, prieſt of Jupiter, and Eurydice. They begging her to ſhew them ſome water, ſhe laid the child down on the graſs, and conducted them to a well. In her abſence, a venomous ſerpent killed the child; upon which the nurſe, out of an exceſs of grief, grew deſperate. The chiefs, at their return with her, killed the ſerpent, buried the young Opheltes, and, to divert Hypſipyle, inſtituted the *Nemean games*.

Ælian ſays, they were indeed the ſeven chiefs going to the ſiege of Thebes, that inſtituted them; but he adds, that it was in favour of Pronax.

Pauſanias refers the inſtitution of them to Adraſtus; and their reſtoration to his deſcendants.

Laſtly, Hercules, on his victory over the *Nemean* lion, augmented the games, and conſecrated them to Jupiter Nemeus.

The games were opened with ſacrificing to *Nemean* Jove, appointing him a prieſt, and propoſing a reward for ſuch as ſhould be victors in the games.

They were held every three years, in the month called *Panemus* by the Corinthians, and *Bucatius* by the Athenians.

The Argians were the judges, and ſat clothed in black,

to express the origin of the games. As they were instituted by warriors, none at first were admitted to them but military men, and the games themselves were only equestrian and gymnic; at length they were open to the people, and other kinds of sports were introduced.

The conquerors were crowned with olive, till the time of the war with the Medes; when a blow they received in that war, occasioned them to change the olive for the smallage, a funeral plant: though others maintain, that the crown was originally smallage, on account of the death of Opheltes, otherwise called Archemorus; this plant being supposed to have received the blood, which ran from the wound made by the serpent.

NEMESIA, in *Antiquity*, a religious solemnity in memory of deceased persons, so called from the goddess *Nemesis*, who was thought to defend the relics and memories of the dead from injuries.

NEMINE *contradicente*, i. e. none contradicting it; a term chiefly used in parliament, or any public assembly, when any matter is carried with the content of all the members.

NENIA, or NÆNIA, in the *Ancient Poetry*, a kind of funeral song, sung to the music of flutes, at the obsequies of the dead.

The word comes from the Greek νηνεμος; on which Scaliger observes, that it should be written in Latin *Nenia*, not *Nœnia*.

Authors represent them as bad compositions, sung by hired women-mourners, called *præficæ*. The first rise of these *nenia* is ascribed to the Phrygians.

Guichart notes, that *nenia* was anciently the name of a song, sung by nurses, to lull children asleep; and conjectures it to come from the Hebrew נין *nin*, *child*.

In the heathen antiquity, the goddess of tears and funerals was called *Nenia*, whom some suppose to have given that name to the funeral song; and others to have taken her name from it. Some will have the one, and some the other, formed by onomatopœia, from the sound or voice of those that weep.

NENUPHAR. The ancient writers on the materia medica have all mentioned a peculiar species of this plant, under the name of *nenuphar indicum*. The roots of this they call BEL, and Avicenna says, that they have the same virtues with the mandrake.

NENUPHAR, in *Botany*, is also a name used by some authors for the *water*-LILY.

NENUPHARINI, a name given by the adepts to a kind of imaginary spirits which they suppose to inhabit the air, and to direct and govern many things on earth.

NEOCORI, Νεωκοροι, among the *Ancients*, persons whose business it was to take care of temples, and other consecrated places. They were otherwise called ÆDITUI.

NECENIA, Νεωνια, in *Antiquity*, a festival celebrated in honour of Bacchus, when the new wine was first tasted.

NEOMENIA, Νεομηνια, in *Antiquity*. See NUMENIA.

NEOMENIA, in *Chronology*, &c. a term used for the new moon.

Some say, the Jews reckoned two kinds of *neomenia*, or new moons; the first on the day of her conjunction with the sun; the second on that of her apparition or phasis; and add, that they celebrated two passovers, on account of the uncertainty which of these days it should be held on.

P. Hardouin, on the contrary, maintains, they had no other *neomenia* but that of the moon's conjunction with the sun; which it was easy to ascertain by astronomical calculation: whereas the other was liable to mistakes; the moon sometimes not shewing herself till four or five days after conjunction.

NEOPHYTES, Νεοφυτοι, in the *Primitive Church*, were new Christians; or the heathens newly converted to the faith.

The word signifies *a new plant*; being formed of the Greek νεος, *new*; and φυω, *I produce*; q. d. *newly-born*; baptism, whereby they commenced *Neophytes*, being a kind of new birth.

The fathers never discovered the mysteries of their religion to the *Neophytes*.

The term *Neophyte* is still applied to the converts which the missionaries frequently make among the infidels. The Japonese *Neophytes*, in the latter end of the fifteenth and beginning of the seventeenth century, are said to have shewn prodigies of courage and faith, equal to any known in the primitive church. See CATECHUMEN.

NEOPHYTES has formerly likewise been used to denote new priests, or those first admitted into orders; and sometimes, the novices in monasteries.

NEOPTOLEMIA, Νεοπτολεμια, in *Antiquity*, a festival celebrated by the Delphians with much pomp and splendor, in memory of Neoptolemus, the son of Achilles, who was slain in an attempt to sack Apollo's temple, which he undertook in revenge of his father's death, to which that god was accessary.

NEOTTIA, in *Botany*, the name given by some to the plant called by Tournefort and others NIDUS *avis*, and by Rupius *corallorhiza*. Linnæus makes both the *nidus avis* and *corallorhiza*, distinct species of the OPHRYS.

NEP, NEPETA, in *Botany*. See CATMINT.

NEPA, a word used by naturalists sometimes to express a *scab*, sometimes for a *scorpion*, and sometimes for a plant, called by the botanists *genista Spartium*.

NEPA, in the Linnæan system of *Zoology*, is a genus of the *hemiptera* class of insects; distinguished by an inflated back; four wings that are complicated in form of a cross, and in the fore part coriaceous; and the anterior feet are cheliform; and the other four ambulatory. There are seven species.

NEPENTHE, or NEPENTHES, Νηπενθης, formed of the privative νη, *non*, or *absque*, and πενθος, *luctus*, *dolor*, in *Antiquity*, a kind of magic potion, which made persons forget all their pains and misfortunes.

The *nepenthe*, mentioned in ancient authors, was the juice or infusion of a plant, now unknown: Homer says it was a plant of Egypt; and adds, that Helena made use of it to charm her lords, and make them forget their pains.

Some authors say it was the plant we call *bolonium*, others, *bugloss*, whose juice infused in wine has this effect. M. Petit has a dissertation on the ancient *nepenthe*.

NEPENTHE, in *Pharmacy*, is a name given to a kind of opiate, contrived by Theo. Zwingerus, from the great opinion he had of its giving ease in all manner of pain.

NEPENTHES, in *Botany*, the name given by Linnæus to a genus of plants of the *gynandria tetrandria* class, the characters of which are these: the perianthium is divided into four roundish segments; there are no petals, and scarce any stamina: but four antheræ are affixed to the stylus near its top; the pistil has an extremely slender germen; the style is pointed and of the length of the cup; and the stigma is obtuse; the fruit is an oblong, columnar, truncated capsule, faintly quadrangular, consisting of four cells, and made up of four valves. The seeds are numerous, pointed, and of a chaffy structure, and are shorter than the capsule.

NEPER's, NAPIER's, or NAPIER's *bones*, an instrument, whereby multiplication and division of large numbers are much facilitated and expedited; so called from its inventor J. Neper, baron of Merchiston, in Scotland.

Construction of NEPER's *bones*. Five rods, plates, or lamellæ, are provided of wood, metal, horn, pasteboard, or other matter (*Tab. Algebra, fig.* 12.), of an oblong form, and divided each into nine little squares; each of which is resolved into two triangles by diagonals.

In these little squares are written the numbers of the multiplication-table; in such manner as that the units, or right-hand figures, are found in the right-hand triangle; and the tens or the left-hand figures, in the left-hand triangle; as in the figure.

Use of NEPER's *bones in multiplication*. To multiply any given number by another; dispose the lamellæ in such manner, as that the top figures may exhibit the multiplicand; and to these, on the left-hand, join the lamellæ of units: in which seek the right-hand figure of the multiplicator; and the numbers corresponding thereto, in the squares of the other lamellæ, write out, by adding the several numbers occurring in the same rhomb together, and their sums. After the same manner write out the numbers corresponding to the other figures of the multiplicator; let them be disposed under one another, as in the common multiplication, and lastly, add the several numbers into one sum.

For example; suppose the multiplicand 5978, and the multiplicator 937. From the outermost triangle on the right-hand (*Tab. Algebra, fig.* 12.) which corresponds to the right-hand figure of the multiplicator 7, write out the figure 6, placing it under the line. In the next rhomb, towards the left, add 9 and 5; their sum being 14, write the right-hand figure, viz. 4, against 6; carrying the left-hand figure, 1, to 2 and 3, which are found in the next rhomb. The sum 8, join to 46, already put down; after the same manner, in the last rhomb, add 6 and 5, the latter figure of the sum 11, put down as before, and carry 1 to the 3 found in the left-hand triangle; the sum 4 join, as before, on the left of 1846: thus you will have the factum of 5978 into 7; and after the same manner will you have the factum of the multiplicand, into the other figures of the multiplicator: the whole added together gives the whole product.

Use of NEPER's *bones in division*. Dispose the lamellæ so, as that the uppermost figures may exhibit the divisor; to these, on the left hand, join the lamellæ of units. Defcend under the divisor, till you meet those figures of the dividend, wherein it is first required, how oft the divisor is found, or at least the next less number, which

is to be subtracted from the dividend; the number corresponding to this, in the place of units, write down for a quotient. By determining the other parts of the quotient after the same manner, the division will be completed.

For example; suppose the dividend 56013806937
5601380, and the divisor 5978; 53802
since it is first asked how often 5978 is found in 560138, descend 22118
under the divisor (*Vid. Algeb. fig.* 12.) till in the lowest series 17934
you find the number 53802, approaching nearest to 56013; the 41846
former whereof is to be subtracted out of the latter, and 41846
the figure 9 corresponding 00000
thereto in the lamella of units write down for the quotient. To the remainder 2011, join the following figure of the divisor 8; and the number 17934 being found, as before, to be the next less number thereto, the corresponding number in the lamella of units, 3, is to be written down for the quotient: and the subtraction to be continued as before. After the same manner the third and last figure of the quotient will be found to be 7; and the whole 937.

NEPETA, in *Botany*. See CATMINT.

NEPHALIA, among the Greeks, a festival called the feast of sober men, at which the Athenians offered to the sun and moon, to Aurora and Venus, a drink made of water and honey. They burnt all sorts of wood on the occasion, except the vine and fig tree.

NEPHEW, a term relative to uncle and aunt; signifying a brother's or sister's son, who according to the civil law, is in the third degree of consanguinity; but, according to the canon law, in the second.

The word is formed from the Latin *nepos*; which in the corrupt ages of that language signified the same: though anciently and properly it denoted a grandson.

NEPHRITIC, NEPHRITICUS, *nephriticus*, formed of *νεφρος*, *ren*, *kidney*, something that relates to the kidneys. See KIDNEY.

NEPHRITIC *colic*. See COLIC.

NEPHRITIC *stone*, *lapis* NEPHRITICUS, a sort of precious stone; so called from its extraordinary virtues against the stone and gravel in the kidneys.

It is a species of JASPER, commonly of an uniform dusky green colour; but sometimes variegated with white, black, or yellow. It seems only to differ from jasper in its being harder, and always without any thing of red.

It is brought chiefly from New Spain, where it is sometimes found in pieces large enough to make moderate cups. There is some, likewise, found in Old Spain, and Bohemia.

This stone was once very dear, by reason of the wonderful virtues ascribed to it. A cup made of it was sold for 1600 crowns, in the time of the emperor Rudolphus II.

The best for medicinal use is of a greyish green, fat and unctuous, like talc of Venice.

The Indians of New Spain, who first discovered its use, and taught it the Europeans, wear it hung about their necks, after having cut it in various figures, chiefly of the beaks of birds: whence some charlatans take occasion to counterfeit it, by cutting other green stones into like figures, and sell them at great prices, to those who have an opinion of their *nephritic faculty*.

NEPHRITIC *wood*, *lignum* NEPHRITICUM, a kind of medicinal wood growing in New Spain, chiefly in the kingdom of Mexico; called by the Indians *coalt* and *tlapalcepatli*, as being reputed *sovereign* against *nephritic* pains.

Dr. Lewis says, he has never known its being given medicinally, and that it is not received in practice.

It must be chosen well cleared of its bark and rind; it is of a bitter taste, and a dusky yellow colour: but when infused in cold water, gives it a sky-blue tincture, when viewed by a false light, and a gold colour by a true one: a little of any acid being mixed with the tincture, both these colours disappear; but a little oil of tartar restores its sky-blue.

Some substitute ebony, and others red Brasil wood, for *lignum nephriticum*; but the deceit becomes apparent by infusing it in water. See TRANSMUTATION *of Colours*.

NEPHRITICS, *Nephrica*, medicines proper for diseases of the kidneys, particularly the stone.

Such, particularly, are the roots of althæa, dogs-grass, asparagus, *tagia*, pellitory of the wall, mallows, pimpinella, red chick-peas, peach-kernels, turpentine, lapis nephriticus, and lignum nephriticum, which see.

NEPHRITIS, or NEPHRITICUS *dolor*, *νεφριτις*, q. d. *disease of the reins*, formed from *νεφρος*, *ren*, in *Medicine*, a name given to a painful disease, occasioned by the stone or gravel in the kidneys.

NEPHRITIS, in *Medicine*, is likewise used for an inflammatory affection of the kidneys, owing its origin to a sanguinary congestion of blood in them, which nature seems to have intended to direct to the internal, hæmorrhoidal vessels, thence to be discharged to ease her of the load of a plethora.

The simple *nephritis* is thus carefully to be distinguished from the calculose one; for the former may, for a long time, affect a patient without any thing of a stone being in the case; and, on the contrary, a stone may be long lodged in the kidneys, without its bringing on any such complaint as the *nephritis*.

In the simple *nephritis* there is always a sensation of pain and heat about the loins, which is plainly perceived to lie deep within the flesh, but is never very acute. On the contrary, in the calculose *nephritis*, the pain is violently sharp.

In the simple *nephritis*, the urine, after it has stood some time, shoots to the sides of the pot pellucid crystals of a reddish colour. But, in the calculose, the heavy matter immediately precipitates itself to the bottom, and is fabulous and gritty; and the simple *nephritis* is always greatly relieved by a gentle motion of the body, as walking, or the like; whereas all motion of the body exasperates the calculose *nephritis*.

The *nephritis* is distinguished also from the ischiatic pains, which sometimes run up to the same parts, by its being evidently perceived to lie deep within the flesh, whereas those pains affect the external muscles; yet there is such a connection and consent of parts in these cases, that not unfrequently the one is taken for the other.

Signs of it. The inflammation begins with a pain in the region of the loins, which does not usually affect both, but only, or at least principally, one side, usually the left; often shooting down by the ureters to the bladder, and by the spermatic cord to the testicle. The pain is at first tensive and dull, but afterwards becomes more acute; in the beginning it is often attended with a chillness, and general trembling, which is succeeded by a heat, and acrid gnawing, scarce to be supported; and this is usually attended with a want of appetite, and loss of strength, and a continual, though not violent thirst. The sleep is unsound, and there usually is either a dull pain in the head, or a vertiginous complaint, more or less violent; and very frequently nausea, and reachings to vomit, attend the fits, or prognosticate the access of them. The patient lies most easily on the affected side, and feels great uneasiness when he endeavours to walk or sit upright.

The pain never extends itself down the whole thigh, nor is that ever wholly numbed, or rendered torpid by it; and the disorder does not seem continual, but attacks the patient at different times, and these after considerably long intervals, if he live regularly. The bowels are usually costive at the time of the fits, and there is a frequent want of making water, though very little is voided at a time, and that thin, when the pain is violent; when it is more obtuse, the urine is commonly thick, and has, as it were, threads in it, of a sort of mucilaginous matter; and to this it is to be added, that sometimes the spermatic vessels which run to the testes become hard and tumid.

Men are more subject to this disease than women, and of those, such principally as are plethoric; and people in the middle and later periods of life, are, in general, more subject to it than those who are younger. In general, young people are not subject to this disease, unless it be from an hereditary disposition, or some very powerful, and violent, external causes.

None so often fall into it as those who have omitted the usual evacuations, and afterwards fall into violent exercises; and finally, people who have the gout and the sciatica, are usually also *nephritic*.

Causes of it. These are principally the suppression of natural evacuations; or the omission of habitual artificial ones; the abuse of hot medicines of the diuretic kind, such as the oils of turpentine, and juniper, and the balsam of sulphur; as also the too frequent use of venery, and the taking medicines to provoke to it; violent passions, or fatiguing exercise; external injuries by blows, falls, or the like; and the use of a too hot diet, and too much of strong liquors.

It may likewise proceed from lying too soft, too much on the back, involuntary contractions or spasms in the urinary vessels, &c. and from any of those causes that produce an inflammatory fever.

Prognostics. The simple *nephritis* may usually be cured, if properly treated, but the calculous one scarce ever can; and though all inflammations of the internal parts are justly accounted very dangerous, yet this is the least so of all others, because the urine continually passing through the part, absterges and cleanses it, and prevents corruption,

ruption, or gatherings of matter. The greatest danger is in such as have a disposition to generate calculous matter, and to hectics. In these cases the disease is apt soon to change from its simple nature.

It is very rare that both kidneys are seized with this distemper, but usually the left alone suffers by it: the more inflammatory the state of the body is, the worse it is with persons afflicted with this disease, and the more they are subject to it: thus young people who have often a turgescence of blood, are more frequently subject to this disease than old persons, and are with more difficulty cured of it: and it is an observation as old as Hippocrates, that the coming on of hæmorrhages from the internal hæmorrhoids cures this disease.

If the disease is protracted beyond the seventh or eighth day, and there is a stupor or heaviness of the part, with frequent returns of chillness and shivering, &c. there is reason to suspect that matter is forming in the kidneys, and that an abscess will ensue.

Method of cure. In the time of the fit, the first thing to be done is to bleed; and if the pain and inflammation continue, the operation may be repeated. The belly should be opened by a clyster of the emollient kind, prepared of milk or broth, to which, if necessary, may be added a little salt and honey, or manna. Simon Pauli expressly directs, from repeated experience of its good effects, a decoction of the herb veronica, or speedwell, with some oil, and a little salt. After this powders of nitre, cinnabar, and tartarum vitriolatum should be taken every three hours; and, towards the evening there should be mixed with one of these doses, eight grains of diaphoretic antimony, and four of crab's eyes. Emulsions of the cold seeds in the cooling simple waters, are also of great use; and to the common seeds used on this occasion, may be added those of poppies, and of carduus Mariæ. In the mean time external applications may also be used with some success; such as cloths dipped in warm water, or bladders filled with it; or with a decoction of chamomile flowers, adding a little saffron, and mixed with about a third part of new milk; or bags of chamomile, melilot, and fenugreek seed dry, and heated at the fire; as also the spirits of serpyllum, and the like, and the soap plaister: to all these may be added the use of leeches, applied to the hæmorrhoidal veins, which are, indeed, a great relief in all the distemperatures of the urinary parts; and, finally, during the whole course of the cure, refrigerating and diluting liquors are to be drank in large quantities, as clear whey, or balm tea sweetened with honey, decoction of marshmallow roots, with barley and liquorice, &c. And the food must be thin and light, as panada, small broths, with mild vegetables, and the like.

The same general course is to be followed, when gravel or a stone is lodged in the kidney; but when they are lodged in the ureter, it will be proper, beside the fomentations, to rub the part with a little sweet oil, and to give gentle diuretics; as juniper-water, sweetened with the syrup of marshmallow; a tea-spoonful of the sweet spirits of nitre, with a few drops of laudanum, may be occasionally mixed with the patient's drink. He should also take exercise on horseback, or in a coach, if he be able to bear it.

After the fit, the necessary treatment to prevent a return, is to bleed regularly, spring and autumn; to take, at times, gentle purges of rhubarb, sena, and the like; to keep the hæmorrhoidal discharges in their proper state; and the habitual costiveness which usually attends people in this disease is to be taken off by a moist and lubricating diet; and wine and strong liquors are to be avoided.

Those that are subject to this disorder, should use moderate exercise, and neither lie too hot, nor too much on their back.

When matter in the urine shews, that an ulcer is formed in the kidney, the patient must carefully abstain from all acrid, sour, and salted provisions; and live chiefly on mild mucilaginous herbs and fruits, and broth of young animals. His drink may be whey, and buttermilk that is not sour; which some have reckoned a specific remedy in ulcers of the kidney: chalybeate waters have been likewise found beneficial. Junker Consp. Med. p. 216, &c. Bechan's Dom. Med. p. 328, &c.

The Greeks also gave the name *nephrites*, to the first vertebra of the loins, from its neighbourhood to the kidneys.

NEPHROMETRA, a name given by some authors to the muscles of the loins, called by the generality of medical authors *psoæ*.

NEPHROTOMY, formed of νεφρος, *kidney*, and τομη, *section*, in *Surgery*, the cutting into the kidneys, in case of the stone being lodged there, and taking it out in the same way as from the bladder.

This is an operation which has been very little practised, and usually supposed to be attended with great danger: few authors who have treated of these diseases have so much as mentioned this operation, and the few that have named it, have generally condemned it. Simibaldus fancying that it was an operation anciently practised, strove very earnestly, indeed, to have it revived. He has called in the opinion of Hippocrates to support his account of its having been done with safety, and advises the surgeons to try their hands on brutes first, and accustom themselves to the operation, and then not to fear it in regard to men.

It is certain that a stone in the kidney is so terrible a disease, that it is very much to be wished that some safe operation could be invented to cure it; but it is making too free with Hippocrates, to say that he countenances or directs such an operation in general. His words seem to express only the making an incision near the kidney; but even if they are to be understood as directing the cutting into it, it is under such restrictions, that opportunities will very seldom offer; and when they do, a common surgeon would not scruple performing all that is directed, without either consulting Hippocrates, or trying his skill upon brutes. Hippocrates only advises it in case of a swelling and impostumation, where there is matter formed, and the tumor manifests itself upon the surface. In this case every surgeon would know it was his business to make an incision. Phil. Trans. N° 223. p. 334.

Cases requiring this are frequent, and not even without a stone.

The general opinion of authors is against the operation; and the most famed among those who have treated of wounds of the kidneys say, that any wound which enters into the pelvis is mortal. Yet this opinion, though general, is not certain or determinate; and we have an account in the Philosophical Tranfactions, of the operation of *nephrotomy* being performed with success, by Marchetti, of Padua, on Mr. Hobson, the English consul at Venice. Phil. Trans. N° 223. p. 337.

NEPOTISM, a term used in Italy, in speaking of the authority which the pope's nephews and relations have in the administration of affairs; and of the care the popes take to raise and enrich them.

Many of the popes have endeavoured to reform the abuses of *nepotism*: at present, *nepotism* is said to be abolished. Leti has wrote expressly on this subject, *Il Nepotismo*.

NEPTA, a name used by some authors for the *asphaltum*. It seems a corruption of *naphtha*.

NEPTUNALIA, feasts held among the ancients, in honour of Neptune.

The *Neptunalia* differed from the *Consualia*, in that the latter were feasts of Neptune, considered particularly as presiding over horses, and the manege. Whereas the *Neptunalia* were feasts of Neptune in general, and not considered under any particular quality. They were celebrated on the 10th of the calends of August.

NEPTUNE, in *Mythology*, the son of Saturn and Rhea, and brother of Jupiter and Pluto. He is commonly represented standing, with his trident in his right hand, which was his peculiar sceptre, as lord of the Mediterranean seas, and seems to have been used by him chiefly to rouse up the waters; for we find sometimes that he lays it aside, when he is to appease them; but he resumes it, when there is any occasion for violence. Virgil, *Æn.* 1. v. 612. makes him shake Troy from its foundations with it; and in Ovid, Met. 1. v. 284, it is with the stroke of this, that the waters are let loose for the general deluge. The dolphin is in his left hand, and he treads on the beak of a ship; to shew that he presided over the seas, or more particularly, over the Mediterranean sea; which was the great, and almost the only scene for navigation, among the old Greeks and Romans. The poets have described this god, as passing over the calm surface of the waters, in his chariot drawn by sea-horses. The fine original description of this is in Homer; from whom Virgil, *Æn.* 1. v. 155. and Statius Achil. 1. v. 60. have copied it. A triton is sometimes represented on each side, as guiding those that draw the chariot of *Neptune*. His aspect in all the best figures of him is majestic and serene. The lower sort of artists exhibit him sometimes with an angry and disturbed air: and one may observe the same difference in this particular, between the great and inferior poets, as there is between the good and bad artists. Thus Ovid. Met. 2. v. 272. describes *Neptune* with a sullen look; whereas Virgil, *Æn.* 1. v. 139. expressly tells us, that he had a mild face, even when he is reprehending him in a passion. *Neptune* had a great number of temples erected to his honour, as well as feasts and games established in token of his respect, both in Greece and Italy. Spencer's Polymetis, p. 65. p. 215, &c.

NEPTUNE's *cup*, a name given by naturalists to a remarkable species of marine insects, which is never found affixed to any solid body, but always loose, and rolling about at the bottom of the sea. Its usual size is about five inches in height, and six or seven in diameter at the base. It gradually becomes narrower from the top to

the ſummit, where it terminates in a round end, ornamented with cluſters of a foliaceous ſort of ſubſtances, reſembling a cock's comb, but of the ſame matter with the reſt of the plant.

Its internal ſurface is very different from this: it is lightly furrowed down the ſides, and beſet with a number of ſmall protuberances, with obtuſe points. Some of theſe, when ſmall, are found with a pedicle growing to them. This is always of a very briſtle like ſubſtance, and it is probable that all thoſe found looſe had originally ſuch pedicles, by which they adhered to ſome ſolid body, in the manner of the corals, and other marine like ſubſtances; but that its extreme briſtleneſs occaſions it to be ſoon broken off, by the motion of the water, after which the plant rolls looſe about, and takes in its nouriſhment at its ſeveral pores, by means of the water which every way ſurrounds it.

It is not probable that theſe and the like marine ſubſtances are nouriſhed only by ſea water; but that there is in the ſea a ſort of mud continually formed out of the decayed particles of animals, and the ſofter vegetables, which may be ſuppoſed much to reſemble the common vegetable mold in its uſes, as it has much the ſame origin; and this, or at leaſt its finer and lighter parts, may be conveyed by water into the pores of theſe ſuppoſed plants, and nouriſh them. Mem. Acad. Par. 1700.

NEPTUNINS, in *Mythology*, were ſea-nymphs, ſo called, becauſe they were the deſcendants of NEPTUNE.

NERANTZIUM, in *Botany*, a name given by ſome of the Greek writers to the citron tree. The ancient Greeks were not acquainted with the word, and it ſeems to have been formed in the barbarous ages from the word *naranga*, the name by which the Arabian phyſicians called the ſame fruit.

NEREIDS, NEREIDES, ſea-nymphs, or fabulous deities of the ancients, ſuppoſed to inhabit the ſea.

The *Nereids* were fifty in number, all the daughters of Nereus, by the nymph Doris. Their names and genealogies are deſcribed by Heſiod. See NYMPH.

NEREIS, in *Zoology*, a genus of inſects of the *gymnarthra* kind, the body of which is of a cylindric figure; the tentacula are four in number, but two of them are uſually very ſhort. Hiſt. Inſect. p. 92.

Authors have deſcribed this genus under the name of SCOLOPENDRA *marina*.

NEREIS, in the Linnæan ſyſtem of *Zoology*, is a genus of the *mollioſa* order of worms, the body of which is creeping, oblong, and linear, the lateral tentacula are pencilled, the mouth is unguiculate, and above it there are plumoſe tentacula. There are eleven ſpecies.

NERFLING, in *Zoology*, the name of a freſh water fiſh of the leather-mouthed kind, common in ſome of the lakes in Germany, and there called alſo the *ruff* or *ſterve*, and ſeeming to be the ſame with the common Engliſh RUDD.

There are two kinds of this fiſh, the fleſh of the one of which, when dreſſed, is white, and that of the other yellowiſh or reddiſh. The latter kind is moſt valued.

NERION, in *Botany*. See OLEANDER.

NERITA, a genus of ſhell *fiſh*, of the nature of the ſemicircular-mouthed cochlear, and comprehended under the general term *cochlea* SEMILUNARES. See *Tab. of Foſſils, claſs* 9.

NEROPHIDION, in *Ichthyology*, a name given by Schoneveldt, and ſome others, to that ſpecies of the *acus* or *ſyngnathus* of Artedi, which is called by that author the hexagonal-bodied *ſyngnathus* with the pinnated tail; and by others, the *acus ariſtotelis*, and *acus ſecunda ſpecies*, and *rydii*; by ſome alſo, *blennus*.

NERVE, NERVUS, in *Anatomy*, a round, white, long body, like a cord, compoſed of ſeveral threads, or fibres, deriving its origin from the brain, or the ſpinal marrow, and diſtributed throughout all parts of the body; ſerving for the conveyance of a peculiar juice, by ſome called *animal ſpirits*, for the performance of ſenſation, and motion.

NERVES, *origin of the*. From every point of the cortex of the brain there ariſe minute medullary fibres; which, in their progreſs, uniting together, at length become ſenſible; and thus conſtitute the medulla of the brain, and the ſpine.

Hence they are continued, and, in their farther progreſs, become diſtinguiſhed, or ſeparated, by coats which are detached to them from the dura and pia mater, into ſeveral diſtinct faſciculi, or *nerves*, reſembling in the poſition of their component fibrillæ, ſo many horſes tails, wrapped up in a double tunic.

It is probable, that the medullary fibres of the cerebellum, riſing up toward the fore-parts of the medulla oblongata, do part of them join the *nerves* ariſing thence, but ſo as ſtill to retain their ſeparate origin, progreſs, and functions: the reſt of the fibres of the cerebellum are ſo mixed with thoſe of the brain, as that there is, perhaps, no part of the whole medulla oblongata, or ſpinalis, where there are not found the fibres of each kind; and thus, to conſtitute the body of each *nerve*, both kinds of fibres contribute, though the end and effect of each be quite different.

The *nerves* thus formed, and ſent from the medulla oblongata, and ſpinalis, while within the cranium, are ten pair, though very improperly ſo accounted; inaſmuch as moſt of them do, in reality, conſiſt of ſeveral diſtinct very large *nerves*: from the ſpinal marrow continued without the cranium there ariſe, after the like manner, thirty pair; to which may be added another pair, ſent from the vertebræ of the neck, augmented in its progreſs by branches from the ſecond and third pair, and at laſt joined to the eighth pair.

All theſe, while within the medulla, are pulpous; as ſoon as they quit it, they acquire a ſheath, or caſe, wherewith being defended, they proceed to the dura mater, which is perforated into an open vagina, reaching as far as the foramina of the cranium, deſtined for the tranſmiſſion of the *nerves*; where the nine firſt pair, and the acceſſory pair, aſſuming this vagina, or caſe, paſs ſafely out of the cranium.

The other thirty and one pair deſcend through ſpaces between the commiſſures of the apophyſes of the vertebræ; whence, firm, hard, and well clothed as they are, they are diſperſed through all, even the ſmalleſt points of the ſolid parts of the body yet known.

The coats, or covers, of theſe *nerves*, are every where inveſted with blood-veſſels, lymphatics, and other veſicles of a very tight texture, which ſerve to collect, ſtrengthen, and contract the fibrillæ; and from which many of the phenomena of the *nerves*, and of diſeaſes, are accountable.

As ſoon as the laſt extremities of the *nerves* are about to enter the parts to which they belong, they again lay aſide their coats, and become expanded, either into a kind of thin membranula, or into a ſoft pulp.

Now upon conſidering, firſt, that the whole vaſcular medulla of the brain goes to the conſtituting of the fibrillæ of the *nerves*; nay, is wholly continued into, and ends in them: ſecondly, that, upon compreſſion, tearing, diſperſion, putrefaction, &c. of the medulla of the brain, all the actions uſed to be performed by the *nerves* ariſing thence, are immediately aboliſhed, even though the *nerves* continue entire, and untouched: thirdly, that the *nerves* themſelves are every where found lax, pendulous, crooked, retrograde, and oblique, yet affect motion and ſenſation almoſt inſtantaneouſly: fourthly, that, when cloſe bound or compreſſed, though in all other reſpects entire, they loſe all their faculty in thoſe parts between the ligature and the extremes to which they tend, without loſing any in thoſe parts between the ligature and the medulla of the brain, or cerebellum; it evidently appears, that the nervous fibrillæ do continually take up an humour, or juice, from the medulla of the brain, and tranſmit it, by ſo many diſtinct canals, to every point of the whole body; and, by means thereof alone, perform all their functions in ſenſation, muſcular motion, &c. which humour is what we popularly call ANIMAL *ſpirits*, or the *nervous juice*.

Nor does there appear any probability in that opinion maintained by ſome; viz. that the *nerves* perform all their action by the vibration of a tenſe fibrilla; which is inconſiſtent with the nature of a ſoft, pulpous, flaccid, crooked, wavy *nerve*, and with that nice diſtinctneſs wherewith the objects of our ſenſes are repreſented, and muſcular motions performed.

Now after the ſame manner as the arterial blood is perpetually carried into all the parts of the body furniſhed with thoſe veſſels, ſo we conceive a juice prepared in the cortex of the brain and cerebellum, conveyed thence every moment through the *nerves* to every point of the ſolid body. The ſmallneſs of the veſſels in the cortex, as exhibited in Ruyſch's injections, which yet are only arterious, and therefore incredibly thicker than the laſt emiſſary derived thence, ſhew how ſlender theſe hollow nervous ſtamina muſt be; but the great bulk of the brain, compared with the exceeding ſmallneſs of each fibrilla, ſhews, that their number muſt be great beyond the limits of all imagination.

And again, the great quantity of juice conſtantly brought hither, and violently agitated, will occaſion a conſtant plenitude, openneſs, and action, of theſe little canals. But as freſh juice is every moment prepared, and the laſt is continually protruding the former, as ſoon as it has done its laſt office, it ſeems to be driven out of the laſt filaments into the ſmalleſt lymphatic venulæ, both about the glands, and elſewhere; thence into the lymphatics ſomewhat larger; and again, from theſe to the common lymphatic veſſels with the valves of veins, and, at length, into the veins, and the heart: and thus, like the other

ſuices of the body, does it make its circuit round the body.

Upon the whole, if we conſider the great bulk of the brain, cerebellum, medulla oblongata, and medulla ſpinalis, with regard to the bulk of the reſt of the ſolids of the body; the great number of *nerves* diſtributed hence throughout the whole body; that the brain and carina, that is, the ſpinal marrow, are the baſis of an embryo, whence, according to the great Malpighi, the other parts are afterwards formed; and, laſtly, that there is ſcarce any part of a body but what feels or moves; it will appear very probable, that all the ſolid parts of the body are woven out of nervous fibres, and conſiſt wholly of them.

The ancients only allowed of ſeven pairs, or conjugations, of *nerves*, proceeding from the brain; which, with their functions, they compriſed in theſe two Latin verſes:

Optica prima, oculos movet altera, tertia ſuffat
Quartaque; quinta audit, vagus ſexto eſt, ſeptima linguæ.

But the moderns, as before obſerved, reckon ten, which are as follow:

NERVES *of the brain*, or *cerebrum*, are, the

NERVES, *auditory*, *ſeventh pair*. See AUDITORY *nerves*, and *Seventh pair of* NERVES.

NERVES, *olfactory*, *par olfactorium*, or *firſt pair*. See OLFACTORY *nerves*.

NERVES, *optic*, or *ſecond pair*. See OPTIC *nerves*.

NERVES *which move the eyes*, *oculorum motorii*, or *third pair*, ariſe from the crura of the medulla oblongata, near the annular protuberance; whence they proceed between two branches of the cervical artery; and, paſſing out of the ſkull at an irregular oblong hole, immediately under the former, are ſpent on thoſe muſcles of the eyes called *attollent*, *depriment*, *adducent*, and *obliquus inferior*; except ſome ſmall fibres, ſpent in the muſcles of the upper palpebra. See *Tab. Anat. (Oſteol.) fig.* 5. *lit.* k k.

NERVES, *pathetic*, or *fourth pair*. See PATHETICI.

NERVES, *fifth pair of*, called *nervi innominati trigemini*, the largeſt of all thoſe coming from the brain, have their uſe, as well as diſtribution, more extenſive; ſerving both for ſenſe and motion, for touch and taſte. They ſend branches not only to the eyes, noſe, palate, tongue, teeth, and moſt parts of the mouth and face, but alſo to the breaſt, lower venter, præcordia, &c. by means of the intercoſtals, which are partly compoſed of branches of theſe *nerves*; whence ariſes a conſent, or ſympathy, between thoſe ſeveral parts of the body. See *Tab. Anat. (Oſteol.) fig.* 5. *lit.* n n.

The *nerves* of this pair ariſe anteriorly from the lateral parts of the tranſverſe protuberance of the medulla oblongata, by a great number of filaments cloſely united together, which afterwards form two large flat trunks, one on each ſide. Each trunk runs toward the apex of the neighbouring os petroſum, where it perforates the dura mater, a little below the edge of the extremity of the anterior portion of the ſeptum tranſverſum of the brain. Having detached ſome filaments to the apex of the apophyſis petroſa, it enters the ſinus cavernoſus; and having ſent ſome other filaments to the dura mater, it expands in the ſinus, and forms a kind of plexus, or flat irregular ganglion. The trunk is afterwards divided into three large branches, more or leſs flatted, which run through the cavernous ſinus, and are diſpoſed laterally on one vertical plane. The *firſt branch*, commonly called *nervus ophthalmicus Willisii*, is the ſmalleſt and longeſt of the three, and enters the orbit through the ſphenoidal fiſſure; on which account Winſlow has called it *nervus orbitarius*. This branch is then divided into three ſubordinate rami, or branches, one ſuperior or frontal, one internal or naſal, and one external or lachrymal; and communicates by a filament or two with the *nerve* of the ſixth pair, and with the intercoſtal *nerve*. The *ramus ſuperior* is the moſt conſiderable, and runs along the ſuperior part of the orbit, cloſe to the membrane which lines it, ſending filaments to the fat which ſurrounds the globe of the eye, to the neighbouring membranes, and to the muſculus levator palpebræ. Afterwards it paſſes through the foramen ſuperciliare, and being divided towards each ſide, is ſpent on the neighbouring portions of the muſculus frontalis, orbicularis, and integuments; communicating with a neighbouring ramus of the portio dura of the auditory *nerve*. The *ramus naſalis* runs towards the noſe; firſt of all obliquely over the optic *nerve*, and under the two muſculi levatores; then between the muſculus rectus internus and obliquus major, along the inſide of the orbit, ſending filaments in its paſſage to the ganglion above mentioned, to the muſculi levatores, and through the internal orbitary hole. It afterwards paſſes over the muſculus rectus internus to the great angle of the eye, where it is diſtributed to the

caruncula and ſacculus lacrymalis, to the neareſt portions of the muſculus orbicularis, ſuperciliaris, pyramidalis naſi, and to the integuments. The *ramus lacrymalis* goes chiefly to the glandula lacrymalis, upon which it is diſtributed, and from whence it has its name. Before it reaches the gland, it ſends a ſmall branch to the external lateral part of the orbit.

The *ſecond branch* of the fifth pair, called *nervus maxillaris ſuperior*, goes out of the cranium between the foramen ovale and fiſſure of the os ſphenoidale, paſſing through the foramen rotundum, or maxillare ſuperius of the ſame bone. Immediately after its paſſage, it ſends a filament to the outſide of the orbit, which, having perforated the os malæ, is diſtributed to the parts which cover that bone; communicates with a neighbouring branch of the portio dura of the auditory nerve; and ſends ſmall filaments to the fat in the lower part of the orbit, ſoon afterwards, it is divided into three rami; the firſt of which, called by Winſlow *ſuborbitarius*, is the moſt conſiderable. This runs in the canal of the inferior portion of the orbit, and goes out by the exterior orbitary hole. In its paſſage it ſends ſmall filaments, which, entering the ſinus maxillaris, are diſtributed to the membrana pituitaria in that ſinus, to the ſubſtance of the bone, to the alveoli, to the anterior dentes molares, and to the dentes canini and incifores. It alſo gives a filament to the poſterior molares, and one, which runs along the upper ſide of the arch of the palate, to the union of the oſſa maxillaria. When this ramus has paſſed out of the bony canal, through the foramen ſub-orbitarium anterius, it is diſtributed to the muſculus orbicularis palpebrarum, to the neighbouring muſcles of the noſe and lips, and to the integuments, communicating with a ramus of the portio dura of the auditory *nerve*. The ſecond ramus of the ſuperior maxillary *nerve*, called *palatinus*, runs down before the pterygoide apophyſes of the os ſphenoides, in the canal formed by the os maxillare and os palati; and having paſſed out of that canal, through the foramen palatinum poſterius, it is diſtributed by ſeveral filaments to the glandular coat of the palate, to the ſeptum palati, and muſcles belonging to that part. It alſo ſends filaments to the muſculus pterygoidæus externus, to the peri-ſtaphylini, and to the arch of the pharynx; and others through the ſmall holes in the poſterior part of, or tubercle of the os maxillare, to the ſinus maxillaris, and poſterior dentes molares. The third ramus, called ſphæno-palatinus, paſſes through the bony hole of the ſame name, and is diſtributed to the muſculus pterygoidæus internus, to the poſterior part of the nares, to the neighbouring ſinus ſphenoidalis, and to the tuba Euſtachiana. It alſo ſends a filament through the foramen pterygoides, which joins the inferior maxillary *nerve*. The third branch of the fifth pair, called *nervus maxillaris inferior*, is larger at its origin than the other two: it goes out of the cranium by the foramen ovale of the ſphenoidal bone, and runs between the two muſculi pterygoidæi, below the great ſinus of the lower jaw, where it enters the bony canal of that jaw. As ſoon as it leaves the cranium, it ſends off four principal branches, and before it enters the canal of the lower jaw, it gives off another to the tongue. The firſt branch runs up to the temporal muſcle, on the inſide of which, and between its fibres it is diſtributed. The ſecond branch runs behind the condyle of the lower jaw, where it divides into two filaments, which communicate with the neighbouring ramus of the portio dura of the auditory *nerve*, behind the outſide of the condyle. At the origin of theſe filaments, it ſends off a ſmall ramus, which runs up before the external ear toward the temples, giving filaments to the concha of the ear in its paſſage. The third branch paſſes between the two apophyſes of the lower jaw, perforates the lower part of the temporal muſcle, and gives it ſeveral filaments. Afterwards it bends downward upon the muſculus maſſeter, to which it is chiefly diſtributed, giving filaments to the neighbouring integuments, and communicating with the portio dura of the auditory *nerve*, on the ſide of the os malæ. It terminates by filaments, which go to the muſculus buccinator, to the muſcles of the under lip, and to the integuments of theſe parts. The fourth branch is often no more than a ramus of the third branch, which goes off near its origin. It paſſes over the muſculus pterygoidæus internus, to which it gives filaments, and is diſtributed to the pterygoidæus internus, and to the neareſt portion of the temporalis. It is likewiſe diſtributed to the muſculus buccinator, to the glands of the mouth and muſcles of the lips; and ſometimes ſends off a filament, which runs up upon the concha of the external ear. The branch that goes to the tongue, which may be called nervus lingualis, or hypogloſſus minor, is detached from the maxillaris inferior, as it paſſes between

the

the muſculi-pterygoidæi, and ſometimes a little ſooner. This conſiderable branch leaves the trunk a little above the canal of the lower jaw, runs over the pterygoidæus internus, and gives it ſome filaments. Near its origin, it communicates with the trunk by a ſhort collateral branch, which is ſometimes plexiform: here it ſuſtains a particular filament, which, according to the common opinion, ariſes from it, and goes to the internal ear. This filament has been ſuppoſed to be a recurrent, running up backward through the tympanum, and joining the portio dura of the auditory *nerve*. But Winſlow thinks it comes from the internal ear to that nerve. This lingual ramus paſſes under the lateral part of the tongue, and over the glandula ſublingualis, giving filaments to the neighbouring portions of the muſcles of the tongue, and to thoſe of the os hyoides and pharynx. Having communicated by ſeveral filaments with the extremities of the *nerve* of the ninth pair, it enters the ſubſtance of the tongue, and terminates near its apex. The inferior maxillary *nerve*, before it enters the canal of the lower jaw, ſends filaments to the neighbouring portions of the muſculus pterygoidæus, internus, digaſtricus, &c. It likewiſe detaches a filament or two along the periоſteum, to be diſtributed to the muſculus mylo-hyoidæus, and glandula ſublingualis. After it has entered the canal of the lower jaw, it runs under the alveoli, and diſtributes filaments to each tooth, all the way to the hole near the chin, where it ſends another ramus forward into the diploe, which is diſtributed to the other teeth that lie between that hole and the ſymphyſis of the chin. Winſlow.

NERVES, *ſixth pair of*, the *guſtatorii*, or *motores externi*, are ſmall, but yet a little larger than thoſe of the fourth pair, called the PATHETICI. They ariſe from the union of the medulla oblongata, between the great tranſverſe protuberance and the corpora olivaria; whence they advance to the dura mater, and enter it on the extremity of the production of the os occipitis behind, and a little on one ſide of the ſymphyſis of that bone with the os ſphenoides. Each of theſe *nerves* runs afterwards in the cavernous duplicature of the dura mater, on one ſide of the bottom of the ſella ſphenoidalis, and of the carotid artery, to which it adheres very cloſely, and it there communicates with a branch of the fifth pair, by one or two ſhort filaments. Immediately after, and behind this communication, the motor externus ſends down a filament, which at firſt appears to run from before backward like a recurrent, and preſently enters the large bony canal of the apophyſis petroſa, on one ſide of the internal carotid artery. This nervous filament, which is ſometimes double, is commonly taken for the root or origin of the intercoſtal *nerve*; but Winſlow obſerves, that, as it makes an acute angle, in an oppoſite direction with the *nerve* of the ſixth pair, it ſeems rather to run up with the carotid artery, and to join that *nerve*, than to ariſe from it. The *nerve* of the ſixth pair, which is ſometimes double, or ſplit into two parts, before it enters the dura mater, paſſes afterwards through the ſphenoidal, or ſuperior orbitary fiſſure, to the muſculus rectus externus of the eye. See *Tab. Anat. (Oſſeol.) fig.* 5. *lit.* o o. Winſlow.

NERVES, *the ſeventh pair*, or *auditory*, ariſing from the lateral and poſterior part of the great tranſverſe protuberance of the medulla oblongata, and paſſing out of the ſkull, through a hole of the os petroſum, ſeparate into two branches, or portions, a hard, and a ſoft one.

The hard portion, entering a little ſinus in the upper part of the bone that conſtitutes the barrel of the ear, ſends off a twig, which diſtributes itſelf into the dura mater, except ſome ſmall twigs which go to the membrane that lines the ear, to the internal muſcles that line the ear, and the fine membrane that clothes the inſide of the cavity of the apophyſis mammillaris: after this, the hard branch ſends off two other twigs, one to the eighth pair, the other to the tympanum, whoſe cord it forms; whence, creeping over the malleolus, it goes out of the ear, and ſends a ramification to the tongue. See *Tab. Anat. (Oſſeol.) fig.* 5. *lit.* p p.

The ſame hard branch, coming out of the proceſſus mammillaris, ſends ſome twigs to the maſſeter, and others to the glands about the ear, where it divides into two other ramifications; the interior beſtowed on the glands, the cheek, and the upper lips; the reſt on the lower palpebra, and the external part of the face. The exterior ramification, beſtowing ſome fibrillæ on the glands, out of which it iſſues, divides into two; the upper diſtributed into the quadratus, and outer parts of the under jaw; the lower ſpent on the integuments of the fore and lateral part of the neck, ſome muſcles of the lower jaw, and the maſtoidal muſcle. This portion of the auditory *nerve* is denominated by Winſlow *nervus ſympatheticus minor*.

The ſoft and larger portion of this pair divides into three ramifications; the upper whereof paſſes through a ſmall foramen into the concha, where, expanding, it forms a fine membrane, which lines its inner ſurface: the ſecond and third ramifications are alſo ſpent on the inner parts of the concha, and ſemicircular ducts, which they furniſh with membranes, the immediate organs of hearing. See AUDITORY *nerves*.

NERVES, *eighth pair of*, or the *par vagum*, denominated by Winſlow *nervi ſympathetici medii*, ariſe from the poſterior part of the medulla oblongata, from the great tranſverſe protuberance, and from the anterior part of the corpora olivaria, by ſeveral ſeparate filaments, which are afterwards collected in a faſciculus, that runs towards the anterior part of the foramen lacerum of the baſis cranii, where it perforates the dura mater, immediately before the extremity of the great lateral ſinus. See *Tab. Anat. (Oſſeol.) fig.* 5. *lit.* q q.

This, in its progreſs, is joined by the par acceſſorium, and, a little farther, by a twig of the hard part of the ſeventh pair; and, at the ſecond vertebra of the neck, by the *nerves* that iſſue from the cervical marrow; and detaches ſeveral twigs to the muſcles of the larynx, gula, neck, &c. particularly from a ganglifform plexus, formed by its union with a branch of the intercoſtal. Hence deſcending to the thorax, it makes another plexus under the clavicle, whence ariſes the recurrent *nerve* on the right ſide, as on the left it has its riſe from the trunk of the *nerve* itſelf. The right recurrent is reflected at the axillary artery; the left at the deſcending branch of the aorta; each, running alide the trachea, impart ſome twigs to it, and terminate in the muſcles of the larynx. Their uſe is in the formation and modulation of the voice. Againſt the origin of the aorta it ſends off a branch towards the heart, which dividing into two, the leſſer twiſts about the pulmonary vein; the bigger proceeds to the pericardium, and heart, after having ſent off a twig, which, with others from the intercoſtals, makes the plexus cardiacus ſuperior: proceeding ſtill farther, it ſends out ſeveral ramifications, which, meeting together, make the plexus pneumonicus, whence ariſe fibres that conſtringe the veſſels and veſicles of the lungs. In its paſſage downwards it diſtributes ſeveral branches to the œſophagus, along which it runs.

About the lower vertebræ of the neck the trunk divides into two branches, the external and internal, communicating all along by ſeveral ramifications, and at length reuniting. The reſt of this pair joins with the intercoſtals in the formation of the ſeveral plexuſes in the lower venter, and in them ſeems to terminate.

Along with theſe, and wrapped up in the ſame coat from the dura mater, paſs the

NERVES, *acceſſory*, *par acceſſorium*, which has its origin from the medulla contained in the vertebræ of the neck. Soon after its return out of the ſkull, it leaves the par vagum again, and is diſtributed into the muſcles of the neck and ſhoulders. See *Tab. Anat. (Oſſeol.) fig.* 5. *lit.* r r.

NERVES, *intercoſtal*, called by Winſlow *ſympathetici majores*, or *maximi*, conſiſt of nervous filaments, derived partly from the brain; viz. the branches of the fifth and ſixth pair; and partly from the ſpinal marrow, by thoſe branches they receive from the vertebral *nerves*.

It has been the common opinion, that theſe *nerves* begin by a filament from the ſixth pair belonging to the medulla oblongata, and by two filaments from the fifth pair; and that theſe filaments do at firſt compoſe a very ſmall *nerve*, which runs backward, to go out of the cranium, through the bony canal of the apophyſis petroſa, and increaſes gradually in its courſe downward. But Mr. Winſlow is of opinion, that theſe filaments aſcend from the baſis of the cranium with the internal carotid, and run from behind forward to join the fifth and ſixth pairs; and he has found the angle formed by this union to be turned forward, and ſo very acute, that theſe *nerves* cannot be looked upon as recurrents. The ſituation of theſe *nerves*, in general, is on the lateral parts of the whole twenty-four vertebræ, immediately before the roots of the tranſverſe apophyſes, and likewiſe on the lateral parts of the inſide of the os ſacrum. Through this large extent, they appear like two ropes divided, and in a manner interſected at different diſtances, by many ganglifform tubercles, by means of which they communicate backward with the ganglions of the medulla ſpinalis, by ſhort collateral filaments; and produce forward all their particular ramifications.

In each trunk of theſe *nerves*, before it arrives at the thorax, are two cervical plexuſes, the upper whereof receives a branch from each trunk of the par vagum; the other ſends out ſeveral ramifications to the œſophagus, and aſpera arteria, and particularly a large one to the recurrent *nerve*. From the ſame plexus deſcend two other ramifications to the cardiac plexus, which are joined a little

little lower by a third, from which the intercostal *nerve*, descending to the clavicles divides into two, and embraces and constringes the subclavian artery; thence entering the thorax, it receives three or four twigs from the upper vertebral *nerve*, together with which it constitutes the intercostal plexus; and thence descending along the sides of the vertebræ, and receiving a nervous twig from each of them, to the os sacrum, and entering the abdomen, it forms several considerable plexuses; viz. the lienaris, hepaticus, the two renales, mesentericus magnus, and two little ones in the pelvis. See INTERCOSTAL.

NERVES, *ninth pair of, motrii linguæ, par linguale*, or *nervi hypoglossi externi seu majores*, arise from the middle of the centrum ovale, by three or four small twigs, and go out of the skull near the process of the occiput, and send their branches to the tongue. See *Tab. Anat. (Osteol.) fig.* 5. *lit.* ll.

They may be likewise called *gustatorii*, as they contribute, together with the branches of the fifth and sixth pair, to the sensation of tasting.

NERVES, *tenth pair of*, or *sub-occipital nerves*, arise by two or three branches from the medulla oblongata, just below the corpora pyramidalia and olivaria, or rather at the beginning of the medulla spinalis; whence, reflecting a little backwards, they go out of the skull between the first vertebra of the neck, and the process of the occiput. See *Tab. Anat. (Osteol.) fig.* 3. *lit.* tt.

These are spent on the external muscles of the head and ears.

NERVES *from the spinal marrow*. The *spinal nerves* (i. e. those springing from the medulla after its egress out of the skull, where it lays aside the name *oblongata*, and assumes that of *spinalis*) are thirty pair; of which, seven are reckoned as belonging to the neck, as having their origin thence, and called *cervical nerves*; twelve to the dorsum, or back, and called *dorsal*, or *costal nerves*; five to the loins, called *lumbal nerves*, and five or six that pass out through the os sacrum. See *Tab. Anat. (Osteol.) fig.* 6. *lit.* bb.

NERVES, *cervical*. See CERVICAL.

NERVES, *dorsal*, are in number twelve: these, excepting what the two upper pair contribute to the *brachial nerves*, are generally distributed into the intercostal and abdominal muscles, the pleura, and external parts of the thorax. See *Tab. Anat. (Osteol.) fig.* 6. *lit.* ll.

NERVES, *lumbal*, are five pair: the first of which sends two branches to the lower side of the diaphragm; the second, some twigs to the genital parts, and others, as well as the three following, give the first roots to the *crural nerves*; the rest of the branches of the *lumbal nerves* are distributed into the muscles of the loins, and adjacent parts. See *Tab. Anat. (Osteol.) fig.* 6. *lit.* gg.

NERVES *of the os sacrum* are six pair; the first three or four pair whereof are bestowed wholly on the *crural nerves*, the rest on the muscles of the anus, vesica, and genital parts.

NERVES, *brachial*, are the offspring, partly, of the cervicals, and partly of the dorsals: these, after the several branches whereof they are composed have been variously complicated and united, run but a little way in a trunk before they divide again into several branches, variously distributed into the muscles of the skin and arms. See *Tab. Anat. (Osteol.) fig.* 6. *lit.* ee.

NERVES, *diaphragmatic*, are likewise the offspring of the cervicals: these two, after joining in a trunk, run through the mediastinum undivided, till they arrive near the diaphragm, into which they send off several branches; some into the muscular, others into the tendinous part of it.

NERVES, *crural*, consist of an union of six or seven pair; viz. the three last of the lumbal, and three or four first of the os sacrum: these, after having spent their upper branches on the muscles of the thigh and skin, as far as the knee, proceed in a trunk downwards, which sends its branches to the extremities of the toes, supplying, as it goes, the muscles and skin of the leg and foot: this is the largest and firmest nervous trunk in the body.

NERVE, *sciatic*, is formed of the last two pair of the lumbar, and the first three pair of the nerves of the os sacrum, and runs obliquely backward under the great sinus of the os ilium, and under the musculus pyriformis. As it goes out of the pelvis, it gives a branch to the anus, perinæum, genital parts, &c. Below the trochanter, it is sometimes called *nervus sciatico-cruralis*, and when it has reached the ham, *nervus popliteus*. In the course of its passage along the leg and foot, to the various parts of which it sends several branches, it acquires the appellation of *sciatico-tibialis*, *sciatico-peræus*, *plantaris internus*, and *externus*.

The ancients found, that by cutting, tying, or compressing any *nerve*, or any other way intercepting its communication with the brain, the parts to which it belonged were immediately deprived of all sense and motion. One remarkable instance of this is, the making an animal dumb by tying the *nerves* near the wind-pipe. We read in Galen of a boy who became quite dumb by having both the recurrent *nerves* divided.

The experiment of cutting these *nerves* in brute animals, was repeated and confirmed by Vesalius; and Dr. Martin assures us, he tried it successfully on a pig; nor did the animal recover its voice, as some have suspected it might. As the voice depends on a proper aperture of the glottis, it seems likely that when the recurrent *nerves* are cut, the glottis will always stand open, and be incapacitated from being that at the will of the animal. See Med. Eff. Edinb. vol. ii. art 8.

An anonymous physician offers what he calls an *experimentum crucis*, in proof of the *nerves* being composed of cylindrical canals, containing a fluid: it is the demonstration of the optic *nerve* inflated and dried, which appears canular to the naked eye.

NERVES, *ganglion of the*. See GANGLION.

NERVES, *wounds of the*. Upon the division of a *nerve*, the limb to which that *nerve* was extended becomes instantly rigid, void of sensation, and withers; so that it is no wonder that a man instantly expires, upon the division of those *nerves* which are sent to the heart or diaphragm: a wound also is attended with great danger where the *nerve* is only partially wounded, and not entirely divided; for the wounded fibres contract themselves, and those which remain undivided suffer too great extension, which will bring on most violent pain, spasms, convulsions, inflammations, and gangrenes, and sometimes death itself. Heister's Surg. p. 27.

NERVES *microscopically examined*. Mr. Leeuwenhoeck endeavoured by his microscope to discover the structure of the *nerves* in the spinal marrow of an ox: he saw there with great delight, minute hollow vessels of an inconceivable fineness, invested with their proper membrane, and running out in length parallel to one another, and making up their composition; and though some hundreds of these vessels go to the formation of the least *nerve* that can be examined, he not only discerned the cavities in them, which he computed to be three times less than their diameters, but in some perceived the orifices as plainly as the holes in a pricked paper are to be seen when looked at against the sun. It requires, however, great dexterity and expedition to make this examination with success; for after a thin slice of the spinal marrow is placed before the microscope, in less than a minute's time it becomes dry, and the whole appearance vanishes. Baker's Microscope, p. 145.

NERVES, *capillaments of the*. See CAPILLAMENT.

NERVES, in *Architecture*, denote the mouldings of projecting arches of vaults, or those arising from the branches of ogives, and crossing each other diagonally in Gothic vaults; serving to separate the pendentives.

NERVES, in *Botany*, are long, tough strings, running either across, or lengthwise of the leaves of plants.

NERVINES. See NEUROTICS.

NERVOSA *corpora*, in *Anatomy*. See CAVERNOSA *corpora*.

NERVOSE *leaf*. See LEAF.

NERVOUS *colic*. See COLIC.

NERVOUS *fever*. See FEVER.

NERVOUS *disorders* compose a very numerous class of the diseases incident to mankind. These, whilst under various forms and modes of attack, they exhaust the strength of the body, impair the vigour of the mind, and its power of self-enjoyment. Disorders of this kind proceed from any cause that contributes to relax the body, or depress the spirits; such are excess of study, and want of proper exercise, drinking weak watery liquors, frequent bleeding, purging, vomiting, immoderate venery, great fatigue, want of sleep, anxiety and grief, unwholesome air, &c.

Nervous diseases commonly begin with windy inflations of the stomach and intestines, bad appetite and digestion, vomiting, excruciating pains about the navel, with a rumbling noise in the bowels, costiveness, very unequal discharges of urine, difficulty of breathing, palpitations of the heart, sudden flushings of heat, and at other times sensation of cold, flying pains in the arms and limbs, pains in the back and belly, variable pulse, yawning, sighing, unsound sleep, &c. As the disorder increases, the patient is troubled with head-ache, cramps, and fixed pains in various parts of the body; the eyes are clouded, and often painful; the ears are dull of hearing, and the mind is subject to inquietude, and distressing apprehensions, on the most trivial occasions. But it is observed, that nothing is more characteristic of this disease than a dread of death. As to the regimen which persons labouring under this disorder should use, though they ought never to fast long, they should be careful to avoid all excess

cefs both in eating and drinking; their food should be ſolid and nouriſhing, but of eaſy digeſtion; wine and brandy mixed with water may be drunk with ſafety, and even with advantage, but all weak and warm liquors, as tea, coffee, punch, &c. are hurtful; becauſe they weaken the ſtomach and hurt digeſtion, and thus increaſe the malady. Exerciſe by walking or riding, long ſea-voyages, change of place and company, are of principal importance and uſe in *nervous* complaints; rubbing the body often with a fleſh-brush, or a coarſe linen cloth, is likewiſe beneficial, as it promotes the circulation and perſpiration. Perſons of weak nerves ſhould riſe early, and uſe exerciſe before breakfaſt; they ſhould, as much as poſſible, breathe a cool and dry air, and be kept eaſy and cheerful. They ſhould avoid a coſtive habit, by the occaſional uſe of a little rhubarb, or ſome other mild purgative: an infuſion of ſenna and rhubarb in brandy will ſerve for this purpoſe; and if the digeſtion is bad, and the ſtomach relaxed, the following infuſion will give relief: take of Peruvian bark, an ounce; gentian root, orange-peel, and coriander-ſeed, of each half an ounce; bruiſe theſe ingredients in a mortar, and infuſe them in a bottle of brandy five or ſix days. A table-ſpoonful of the ſtrained liquor may be taken in half a glaſs of water an hour before breakfaſt, dinner, and ſupper. Cold bathing is very ſerviceable in ſtrengthening the *nervous* ſyſtem, unleſs there are particular ſymptoms which forbid the uſe of it. Dr. Buchan ſtrongly recommends to patients afflicted with wind the acid elixir of vitriol; which, he ſays, taken in the quantity of fifteen, twenty, or thirty drops, twice or thrice a day, in a glaſs of water, will expel wind, ſtrengthen the ſtomach, and promote digeſtion. Upon the whole, the ſtricteſt attention ſhould be paid to diet, air, exerciſe, and amuſements, and the medicines ſhould be adapted to the nature and degree of the diſeaſe under which the patient labours. Buchan's Dom. Med. Chap. 43. See HYPOCHONDRIAC and HYSTERIC *affection*.

NERVOUS *ſpirit*, or *juice*, denotes a pure, ſubtile, volatile, humour, better known by the name of *animal ſpirits*; ſecreted from the arterious blood in the cortical part of the brain, collected in the medulla oblongata, and thence driven, by the force of the heart, into the cavities of the nerves; to be conveyed by them throughout the body, for the purpoſes of ſenſation, and animal motion.

Gliſſon, Wharton, and Willis, firſt mentioned the *nervous* juice; but many of our modern phyſicians deny the exiſtence of this juice. See ANIMAL *ſpirits*.

NERVOUS *parts, conſent of the*. See CONSENT.

NEST. See NIDUS.

NESTLINGS, a name given to Canary birds brought up by hand. See CANARY-*bird*.

NESTORIANS, a ſect of ancient Chriſtians, ſtill ſaid to be ſubſiſting in ſome parts of the Levant; whoſe diſtinguiſhing tenet is, that Mary is not the mother of God.

They take their name from Neſtorius, a Syrian, who, of a monk, became a prieſt, and a celebrated preacher; and was at length, after the death of Siſinnius in 428, raiſed by Theodoſius to the ſee of Conſtantinople.

As ſoon he ſhewed a great deal of zeal againſt hereſy, in his ſermons before the emperor; but, at length, taking the liberty to ſay, that he found in ſcripture, that Mary was the mother of Jeſus, but that he no-where found, that Mary was the mother of God; his auditory was ſhocked, and a great part of them retired from his communion.

His writings were ſoon ſpread through Syria, Egypt, and Perſia, where he made many converts, notwithſtanding the vigorous oppoſition of St. Cyril.

But nothing tended ſo much to propagate with rapidity the doctrine of Neſtorius, as its being received in the famous ſchool which had for a long time flouriſhed at Edeſſa. For the doctors of this celebrated academy not only inſtructed the youth in the *Neſtorian* tenets, but tranſlated from the Greek into the Syriac language the books of Neſtorius, of his maſter Theodorus of Moſſueſtia, and the writings alſo of Diodorus of Tarſus, and ſpread them abroad throughout Aſſyria and Perſia.

One of the chief promoters of the *Neſtorian* cauſe was Barſumas, created biſhop of Niſibis A. D. 435. Such was his zeal and ſucceſs, that the *Neſtorians*, who ſtill remain in Chaldæa, Perſia, Aſſyria, and the adjacent countries, conſider him alone as their parent and founder. By him, Pherozes, the Perſian monarch, was perſuaded to expel thoſe Chriſtians who adopted the opinions of the Greeks, and to admit the *Neſtorians* in their place, putting them in poſſeſſion of the principal ſeat of eccleſiaſtical authority in Perſia, the ſee of Seleucia, which the patriarch of the *Neſtorians* has always filled even down to our time. Barſumas alſo erected a ſchool at Niſibis, from which proceeded thoſe *Neſtorian* doctors, who, in the fifth and ſixth centuries, ſpread abroad their tenets through Egypt, Syria, Arabia, India, Tartary, and China.

His capital tenet was, that there are two perſons in Jeſus Chriſt; and that the Virgin was not his mother as God, but only as man.

This doctrine was condemned in the council of Epheſus, ſummoned by Theodoſius the younger, A. D. 431, at which above two hundred biſhops aſſiſted, and Cyril preſided; and Neſtorius was anathematized, without being heard, and depoſed from his ſee.

Neſtorius was not the author of this opinion, but borrowed it at Antioch, where he had ſtudied; and though he was the ſuffering and perſecuted party from the beginning of the controverſy to his death, the flame was firſt kindled by the preſbyter Anaſtaſius. Theodorus Moſſueſtanus, whoſe diſciple he was, had taught the ſame before him.

The abettors of this doctrine refuſe the title *Neſtorians*; alledging, that it had been handed down from the earlieſt times of the Chriſtian church.

In the tenth century the *Neſtorians* in Chaldæa, whence they are ſometimes called Chaldæans, extended their ſpiritual conqueſts beyond mount Imaus, and introduced the Chriſtian religion into Tartary, properly ſo called, and eſpecially into that country called *Kara*, and bordering on the northern part of China. The prince of that country, whom the *Neſtorians* converted to the Chriſtian faith, aſſumed, according to the vulgar tradition, the name of John, after his baptiſm, to which he added the ſurname of Preſbyter, from a principle of modeſty; whence it is ſaid, his ſucceſſors were each of them called Preſter John, until the time of Gengis Kan. But Moſheim obſerves, that the famous Preſter John did not begin to reign in that part of Aſia before the concluſion of the eleventh century. The *Neſtorians* formed ſo conſiderable a body of Chriſtians, that the miſſionaries of Rome were induſtrious in their endeavours to reduce them under the papal yoke. Innocent IV. in 1246, and Nicolas IV. in 1278, uſed their utmoſt efforts for this purpoſe, but without ſucceſs. Till the time of pope Julius III. the *Neſtorians* acknowleged but one patriarch, who reſided firſt at Bagdat, and afterwards at Moſoul; but a diviſion ariſing among them, in 1551, the patriarchate became divided, at leaſt for a time, and a new patriarch was conſecrated by that pope, whoſe ſucceſſors fixed their reſidence in the city of Ormus, in the mountainous part of Perſia, where they ſtill continue, diſtinguiſhed by the name of Simeon; and ſo far down as the laſt century, theſe patriarchs perſevered in their communion with the church of Rome, but ſeem at preſent to have withdrawn themſelves from it. The great *Neſtorian* pontiff, who form the oppoſite party, and look with a hoſtile eye on this little patriarch, have, ſince the year 1559, been diſtinguiſhed by the general denomination of Elias, and reſide conſtantly in the city of Moſoul. Their ſpiritual dominion is very extenſive, takes in a great part of Aſia, and comprehends alſo within its circuit the Arabian *Neſtorians*, and alſo the CHRISTIANS *of St. Thomas*, who dwell along the coaſt of Malabar. It is obſerved, to the laſting honour of the *Neſtorians*, that of all the Chriſtian ſocieties eſtabliſhed in the Eaſt, they have been the moſt careful and ſucceſsful in avoiding a multitude of ſuperſtitious opinions and practices that have infected the Greek and Latin churches. About the middle of the ſeventeenth century the Romiſh miſſionaries gained over to their communion a ſmall number of *Neſtorians*, whom they formed into a congregation or church; the patriarchs or biſhops of which reſide in the city of Amida, or Diarbeker, and all aſſume the denomination of Joſeph. Nevertheleſs, the *Neſtorians*, in general, perſevere, to our own times, in their refuſal to enter into the communion of the Romiſh church, notwithſtanding the earneſt intreaties and alluring offers that have been made by the pope's legate to conquer their inflexible conſtancy. Moſheim.

NET, *in Fiſhing and Fowling*, a contrivance by which to catch fiſh or fowl. See FISHING.

The taking fowls by *nets* is the readieſt and moſt advantageous of all others, where numbers are to be taken.

The making the *net* is very eaſy, and what every true ſportſman ought to be able to do for himſelf. All the tools neceſſary to it are wooden needles, of which there ſhould be ſeveral of different ſizes, ſome round, and others flat; a pair of round-pointed flat ſciſſars, and a wheel to wind off the thread. The packthread is to be of different ſtrength and thickneſs, according to the ſort of birds that are to be taken; and the general ſize of the meſhes, if not for very ſmall birds, is two inches from point to point.

The *net* ſhould be made neither too deep nor too long, for they are then difficult to manage; and they muſt be verged on each ſide with twiſted thread. The natural

colour of the thread is too bright and pale, and is therefore to be altered in many cases, according to the occasion.

The moſt uſual colour is the ruſſet: this is to be obtained by plunging the *net*, after it is made, into a tanner's pit, and letting it lie there till it be ſufficiently tinged; this is of a double ſervice to the *net*, preſerving the thread very greatly, as well as altering the colour. The green colour is given by chopping ſome green wheat, and boiling it in water, then ſoaking the *net* in this green tincture till it have ſufficient colour. The yellow colour is given in the ſame manner, with the decoction of celandine: this gives a pale and faint ſtraw colour, which is the colour of ſtubble in the harveſt time, and is juſt what is wanted. The brown *nets* are intended to be uſed on ploughed fields; the green on graſs grounds, and the yellow on ſtubble lands.

Great care is neceſſary in the preſerving of *nets*; and the principal thing to be conſidered in regard to this is, that all wet rots the threads: whenever they have been uſed in dew or rain, they muſt be hung up to dry in the ſun; and if there is any rent or breach made, it muſt be mended as ſoon as it is diſcovered. In the drying, they muſt be hung as far as may be from the walls, that they may be out of the way of mice and rats, which are very apt to deſtroy them. The utmoſt depth that ſhould be allowed to a *net* for fowl, is two fathom, and the utmoſt length ſix fathom.

The places for uſing fowling *nets* to moſt advantage, are the morning and evening haunts, where the birds come to feed. The ſportſman is to be at the place at leaſt two hours before the time of their coming, and the *net* muſt immediately be ſpread flat and even upon the ground, and the two ends faſtened down with ſtakes. At the lower part there is to be a long cord fixed to the upper edge of the *net*, by means of which it may be immediately raiſed, and pulled over. The ſportſman is to hide himſelf behind ſome natural or artificial ſhelter, at the extremity of this line, and ſome cut graſs muſt be ſtrewed all over the *net*, as it lies on the ground, to hide it from the fowl; and ſome live bird, that has been taken before, ſhould be ſtaked down before the *net*, by way of a ſtall, to draw in the others.

As ſoon as a ſufficient number of birds are within the compaſs of the *net*, it is to be pulled ſwiftly over them, and the fowler having taken thoſe that are under it, may ſtake down two or three more live ones, and ſpread the *net*, covering it with graſs as before. This ſort of ſport may be continued from as ſoon as it is light in the morning till an hour after ſun-riſe; but after that time, the birds have done feeding ravenouſly, and the ſport is over for that day.

NET, *cinque-port*, in *Fiſhery*, a name given to a ſort of ſquare *net*, reſembling a cage, and having five entrances into it, from whence it has the name.

It is a very ſerviceable *net* in any pond or river, and is equally good in ſwift or ſtanding water. In order to make this *net*, there muſt be provided four large and ſtrait poles, anſwerable in length to the depth of the water. The ends of theſe muſt be ſharpened in the manner of ſtakes, and there muſt be notches within a foot of the ſharp part to faſten the *net* to; and at a convenient diſtance, on the poles, there muſt be another ſet of notches, for the faſtening the other ends of the *net*.

The bottom of this *net* is four-ſquare, without any entrance. A boat muſt be taken out with this *net*, to place it properly. The four poles muſt be fixed in the bottom in ſuch a manner, that each may anſwer to the other in a direct line; and they muſt ſtand at ſuch diſtances, that the *net* may be drawn out as ſtiff as poſſible between them. If the *net* is to be fixed in a ſtanding water, this method alone will do very well; but if it be a ſmooth ſtream, ſomething more is neceſſary, otherwiſe the motion of the water will keep the *net* playing about, and this will frighten away the fiſh. To prevent this, four ſtrong ſticks are in this caſe to be faſtened along the tops of the others, ſo as to make a ſort of frame, to ſtreighten and ſtrengthen the others, and keep all tight.

When the *net* is perfectly fixed, it repreſents a cage, and the ſides, top, and bottom are kept ſo firm, that the fiſh do not regard them, but ſeem to take them for weeds; but going in at the entrances, there is no returning, and in rich places great numbers are taken.

NET, *clap*. See CLAP-*net*, and DORING.

NET, *crow*, in *Birding*, a name given to a ſort of *net* contrived for the catching of wild fowl in the winter ſeaſon. This *net* may be uſed in the day-time, and is to be made of double thread, or of fine packthread, and the meſhes are to be two inches wide. The length of the whole ſhould be about ten yards, and the depth about three; it ſhould be verged on the ſides with a ſtrong cord, and ſtretched out in length very ſtiff upon long poles, prepared for that purpoſe. When this *net* is brought to the place where it is to be uſed, it muſt be opened, and ſpread at full length and breadth; then its lower end is to be faſtened all along the whole length to the ground, ſo that it only can be moved up and down; the upper end of the *net* muſt ſtand extended on the long cord, the farther end of it being firſt ſtaked to the earth by a ſtrong cord, about five yards diſtant from the *net*, and ſtanding in an even line with the bottom of the *net*; the other end of the cord muſt reach at leaſt five and twenty yards, to ſome natural or artificial ſhelter, by means of which the ſportſman is to lie concealed from his prey. The *net* muſt be placed in ſuch exact order, that it will play upon the leaſt jerk of the cord, and that muſt always be given ſuddenly, leſt the prey eſcape. This *net* is principally uſed for crows and pigeons, on new-ſown cornfields, and it may alſo be uſed in ſtubble-fields, where the ſtubble will hide the *net* from the fowl. If the meſhes are made ſmaller, it may be uſed at barn-doors and the like for ſmall birds; and a bait of chaff will bring them together under it. But the great uſe of the *crow-net*, is to ſpread it in mornings and evenings where the haunts of wild fowl are, which in hard weather fly in great flocks to and from land, with and againſt the wind, and then fly cloſe to the ground, in open countries and low lands, where there are few hedges. When a whole covey of theſe are within the reach of the *net*, it is to be let go over them, and they will be taken in great numbers at one caſt.

NET, *fold*. See FOLD.

NET, *iramel*. See TRAMEL.

NET, *tunnel*. See TUNNEL.

NET, *water-fowl*. See *Water*-FOWL.

NET, *wolf*. See WOLF.

NET, NEAT, in *Commerce*, ſomething pure, and unadulterated with any foreign mixture.

Thus, wine is ſaid to be *net*, when not falſified or ſophiſticated; and coffee, rice, pepper, &c. are *net*, when the filth and impurities are ſeparated from them.

A diamond is ſaid to be *net*, when it has no ſtains or flaws; a cryſtal, when tranſparent throughout.

NET is alſo uſed for what remains after the tare has been taken out of the weight of any merchandize; i. e. when it is weighed clear of all package.

Thus we ſay, a barrel of cochineal weighs 450 pounds; the tare is 50 pounds, and there remains *net* 400 pounds.

NET-*meaſure*, in *Building*, is when no allowance is made for finiſhing; and in artificer's work, when no allowance is made for waſte of materials.

NET-*produce*, a term uſed to expreſs what any commodity has yielded, all tare and charges deducted.

The merchants ſometimes uſe the Italian words *netto proceduto*, for *net produce*.

NET-*maſonry*. See MASONRY.

NETE, in the *Ancient Muſic*, was a general name for one of the extreme chords of a tetrachord. Some ſay it was the higheſt, and others the loweſt ſound. But perhaps the truth of the matter is, that it was the higheſt or loweſt ſound, according as the aſcending or deſcending ſcales were conſidered. Vide Phil. Tranſ. N° 481. p. 269. See HYPATE.

When the *nete* is ſaid to be one of the extremes of a tetrachord, it is to be underſtood of a tetrachord conſidered by itſelf; for, when tetrachords were combined, the *nete* ſometimes took another name, as appears from the Greek ſcale inſerted under DIAGRAM.

NETE *hyperbolæon*, in the *Ancient Muſic*, the name of the higheſt and moſt acute of the chords of the lyre, or the ancient ſcale, or diagramma.

The word is compoſed of νετη, and ὑπερβολαιων, q. d. *the laſt of the higheſt*; where is underſtood the word *chords*. It anſwered to the A, mi, la, of the third octave of the organ, or the modern ſyſtem.

NETE *diezeugmenon*, in the *Ancient Muſic*, was one of the chords of the lyre, or ſyſtem of the ancients.

The word comes from νετη, and διεζευγμενων, *laſt of the ſeparate*; where is underſtood the word *chords*.

It anſwers to the E, fa, mi, of the third octave of the organ, or modern ſyſtem.

NETE *ſynnemenon*, in the *Ancient Muſic*, the name of the higheſt chord of a tetrachord of the Greek ſyſtem; added to make the b mollis fall between the meſe and parameſe, i. e. between the la and fa.

The word comes from νετη, and συνημμενων, *the laſt of the added*; where is underſtood the word *chords*.

The chord had the ſame ſound with the *paranete diezeugmenon*, or our la by b mollis.

NETHER *vert*. See VERT.

NETHINIMS, among the *Jews*, the poſterity of the Gibeonites, who were condemned by Joſhua to be hewers of wood and drawers of water for the houſe of God.

NETOPION, Νητοπιον, a name given by the ancients to a

very

very fragrant and coſtly ointment, conſiſting of a great number of the fineſt ſpicy ingredients. Hippocrates, in his Treatiſe of the Diſeaſes of Women, frequently preſcribes the *nitrum* in diſeaſes of the uterus; and in other places he ſpeaks of its being poured into the ear as a remedy for deafneſs; theſe compoſitions, by their attenuating qualities, dividing the viſcous and thick humours. The word *nitrum* is alſo ſometimes uſed to expreſs the *unguentum Ægyptiacum*, and ſometimes ſimply for oil of almonds.

NETTINGS, in a *Ship*, are a ſort of grates made with ſmall ropes, and ſeized together with rope-yarn, and are laid in the waiſt of a ſhip, ſometimes, to ſerve inſtead of GRATINGS.

NETTING-*cloth*, in a *Ship*. See SAIL.

NETTLE, *urtica*, in *Botany*, a genus of the *monœcia tetrandria* claſs. Its characters are theſe: it has male and female flowers at remote diſtances, ſometimes on the ſame, and at other times on different plants; the male flowers have empalements compoſed of four roundiſh concave leaves, and have a pitcher-ſhaped nectarium in the center of the flower, and four awl-ſhaped ſpreading ſtamina, terminated by ſummits, with two cells; the female flowers have an oval permanent empalement with two valves, without either petals or ſtamina, but have an oval germen without any ſtyle, crowned by a hairy ſtigma; the germen afterward turns to an oval compreſſed ſeed, which ripens in the empalement. Miller enumerates nine, and Linnæus nineteen ſpecies.

The roots of the common *nettle* are much recommended in medicine: they are powerful diuretics, and are ſaid to have great virtues againſt the ſtone and gravel, and looſen the belly; they cleanſe the blood, and are ſaid to be of great ſervice in hæmorrhages of all kinds, particularly in ſpittings of blood, and overflowings of the menſes. Authors add to this, that they are ſpecifics, by way of antidote, againſt the poiſon of henbane and hemlock; but this we are not ſo well aſſured of. The young ſhoots of the plant are eaten in the ſpring, as good againſt ſcorbutic complaints.

The ancients ſeem to have deſpiſed this plant, from its being common; and, though poſſeſſed of great virtues in medicine, neither the Greeks nor Latins have ſaid much about it; nor have the Arabians, who abound in the imaginary virtues of plants, thought the real ones of this herb worth their conſideration.

It has, however, been more honoured lately, and notwithſtanding its being now the moſt vile and abject plant among us, as well as the leaſt regarded by the ancients, Johannes Frances, an author of conſiderable fame, has publiſhed a treatiſe ſolely upon it; in this he has treated at large on its hiſtory and virtues. He deſcribes its ſtings in a very judicious manner, according to the preſent doctrine of the microſcope, and gives the hiſtory of certain worms of ſingular kinds which feed upon it; and adds its uſe in our own foods as a wholeſome and agreeable pot-herb: in our drink as a ſubſtitute for hops, being as well capable of preſerving it as theſe, and its great ſervice to the farmer in fattening hens.

John Melchiore Dreſchler, in the year 1717, ſuſtained alſo a theſis on the virtues and uſes of this plant, which has been ſince printed, ornamented with ſeveral cuts. In theſe two authors we find the whole account of the ſeveral uſes this common plant has been put to, and may be put to in our manufactures, our domeſtic and medicinal uſes; and, if what they ſay be true, we muſt wonder to ſee ſo much value overlooked in a herb, only becauſe it is common.

An ingenious manufacturer at Leipſic has lately contrived to make ropes and cloth of *nettle*. The ſpecies he uſes for this purpoſe is the *urtica urens maxima*, or great ſtinging *nettle*; and the proceſs of preparing it as follows: having gathered a quantity of the ſtalks ſtill green, though half withered, he dried them over his ſtove; and when the moiſture was entirely exhauſted, bruiſed them ſo as to be able to ſeparate the wood from the bark; by this operation he procured a kind of green hards, which was rubbed and prepared like flax. This new matter being ſpun, he obtained a greeniſh brown thread, very uniform and clear, ſomewhat reſembling worſted. The manufacturer afterwards boiled this thread, when it yielded a greeniſh juice, and became more white, uniform, and ſtrong; ſo that by continuing the preparation, there is reaſon to hope that an excellent thread may be made, and conſequently a ſtrong and laſting cloth; and that it may be employed with advantage, not only by rope-makers, but even by weavers, in making fine ſtuffs.

NETTLE, *dead, lamium*, in *Botany*. See ARCHANGEL.

NETTLE, *ſea*. See MEDUSA, ACTINIA, *Animal Flowers*, and UTICA *marina*.

NETTLE, *ſtinking*. See *Stinking Dead* NETTLE.

NETTLE, *ſtrawberry, fragaria, potentilla*, in *Botany*, a genus of the *didynamia gymnoſpermia* claſs. Its characters are theſe: the flower hath a bell-ſhaped empalement of one leaf, divided into two lips; the upper lip ends in three acute points; the lower lip is cut into two parts; the flower is of the lip-kind; it hath one petal; the upper lip is oval, erect, and indented at the end; the lower lip is reflexed, and ends in three points, the middle one being broadeſt; it has four awl-ſhaped ſtamina under the upper lip, two of which are ſhorter than the other, having oblong ſummits on their ſides, and a four-pointed germen, ſuſtaining a ſlender ſtyle, the length of the ſtamina, crowned by a bifid ſtigma; the germen afterward becomes four berries, each containing a ſingle roundiſh ſeed. There are two ſpecies.

A plant or two of each of theſe ſpecies may be allowed to have a place where there are collections of the different ſorts of evergreen ſhrubs, for the ſake of variety, eſpecially where the different ſorts of ciſtus, phlomis, tree-wormwood, and medicago, are admitted, becauſe they are equally hardy. Miller.

NETTLE, *ſtinking dead, galeopſis*, in *Botany*, a genus of the *didynamia gymnoſpermia* claſs. Its characters are theſe: the flower is of the lip-kind, the chaps broad, and from the baſe to the under lip it is on both ſides ſharply indented; the upper lip is concave, and fawed at the top; the under lip trifid, the middle ſegment being the largeſt, which is crenated; it has four ſtamina, two being ſhorter than the other; in the center is ſituated a quadrifid germen, which becomes four naked ſeeds, ſitting in the rigid empalement. Miller reckons ſix ſpecies, all of them common weeds. Linnæus deſcribes only three ſpecies.

NETTLE-*tree, celtis*, in *Botany*, a genus of the *polygamia monœcia* claſs. Its characters are theſe: it has male and hermaphrodite flowers on the ſame tree; the hermaphrodite flowers, whoſe empalement is divided into five parts, are ſingle, and ſituated above the male, which have no petals, but five ſhort ſtamina; in the center is ſituated an oval germen, which becomes a round berry with one cell, including a roundiſh nut; the male flowers have their empalements divided into ſix parts, and have no germen or ſtyle, but in other parts are like the hermaphrodite. Miller reckons four, and Linnæus three, ſpecies.

The *celtis*, with black fruit, grows in France and Italy; the fruit, which is uſed in medicine, is aſtringent, and binds the belly, but has leaſt of theſe qualities when ripe; the decoction thereof is good for a dyſentery, and for women labouring under an immoderate flux of the menſes.

NEVILLI *oſſa*. See TESTA.

NEURADE, in *Botany*, a name given by Linnæus to a genus of plants of the *decandria decagynia* claſs, called by Juſſieu *ſenebalfrum*. The characters are theſe: the perianthium is very ſmall, and ſtands upon the germen of the piſtil; it is compoſed of one leaf, divided into five ſegments; the flower conſiſts of five equal petals, larger than the leaves of the cup; the ſtamina are ten filaments, of the length of the cup; the antheræ are ſimple; the germen of the piſtil ſtands under the cup, and is of a gibbous figure; the ſtyles are ten in number, and are of the length of the ſtigmata; the ſtigmata are ſimple; the fruit is an orbicular capſule, of a depreſſed figure on the ſurface, and convex underneath, and is every way ſurrounded with prickles; the inner part is divided into ten cells, in every one of which is lodged a ſingle ſeed. There is only one ſpecies.

NEURIS, in the *Writings of the Ancients*, the name given to a ſpecies of marble, otherwiſe called *alaboniſcum*, and *proconneſium*. It was much uſed by the Roman ſtatuaries, and was dug in a ſmall iſland that lay between Paros and Cyzicus. It was of a duſky or bluiſh white, and was variegated with fine and ſlender veins of black, often beautifully diſpoſed, and in the bodies of the naked ſtatues reſembling the courſe of the veins.

NEURITICS, or NERVINES, formed from νευρον, *nervus*, in *Medicine*, remedies proper for diſeaſes of the nerves, and nervous parts; as the membranes, ligaments, &c. Such are betony, lavender, roſemary, ſage, laurel, marjoram, and others among the CEPHALICS.

NEUROBATES, in *Antiquity*, a rope-dancer. See DANCER.

NEUROGRAPHIA, in *Anatomy*, a deſcription of the nerves.

Raim. Vieuſſens, a phyſician of Montpelier, has an excellent treatiſe in Latin, under the title *Neurographia Univerſalis*; where he ſhews, that there are more ramifications of the nerves in the ſkin than in the muſcles and all the other parts.

Duncan, another phyſician of the ſame place, has alſo a treatiſe, called *Neurographia Rationalis*.

NEUROLOGY, Νευρολογια, a diſcourſe of the nerves.

Neurology ſeems to be of leſs extent than *neurography*, inaſmuch as the latter may be underſtood not only of diſcourſes on the nerves, but alſo of figures and engravings, repre-

representing them; whereas the former is restrained to discerning alone. Willis has given a fine *neurology*, in his Anatome Cerebri.

NEUROPHYLLON, in *Natural History*, a name given by Mr. Hayd to a species of *fossile* PLANT, remarkable for the ribbes on the leaf.

NEUROPTERA, in *Zoology*, the name by which Linnæus and Dr. Hill call a class of four-winged insects, from their wings being membranaceous with nerves, and being disposed in a reticulated form. In the Linnæan system there are seven genera comprehended under this class.

NEUTER, a person indifferent, who has espoused neither party, and is neither friend, nor foe.

NEUTER, in *Grammar*, denotes a sort of GENDER in nouns which are neither masculine, nor feminine.

NEUTER, *verb*. See VERB.

NEUTHA, a name given by authors to a pellicle covering the eyes or the ears of a child in the birth, and sometimes the whole face.

NEUTRAL *salts*, among *Chemists*, are a sort of intermediate salts between acids and alkalis; partaking of the nature of both.

Formerly those only were called *neutral* salts, which were composed of acids and alkalis united together to the point of saturation, so that they had no acid or alkaline property, and thence they were called *neutral*. But now this name is commonly extended to combinations of acids with all substances, with which they can so unite, that they lose entirely or mostly their acid qualities; as, for instance, when they are united with earthy or metallic substances.

Mr. Boyle also gives the appellation *neutral* to a sort of spirits, differing, in divers qualities, both from vitious, acid, and urinous spirits. These he also calls *anonymous* and *acidiphorous* spirits.

NEUTRALITY, the state of a person or thing that is *neutral*.

NEW *moon*, *menmenia*, that state of the moon a little before, and a little after, her conjunction with the sun.

NEWEL, in *Architecture*, the upright post which stairs turn about; being that part of the staircase which sustains the steps.

The *newel* is, properly, a cylinder of stone, which bears on the ground, and is formed by the ends of the steps of the winding-stairs.

There are also *newels* of wood, which are pieces of timber placed perpendicularly, receiving the tenons of the steps of wooden stairs into their mortices, and wherein are fixed the shafts and rests of the staircase, and the shafts of each story.

NEWS, *false*. See FALSE *news*.

NEWT, in *Zoology*. See EFT, and LACERTA *aquatica*.

NEWTONIAN *philosophy*, the doctrine of the universe, and, particularly, of the heavenly bodies; their laws, affections, &c. as delivered by Sir Isaac Newton.

The term *Newtonian philosophy* is applied very differently; whence have sprung divers confused notions relating to it.

Some authors, under this *philosophy*, include all the corpuscular philosophy, considered as it now stands corrected and reformed by the discoveries and improvements made in several parts thereof, by Sir Isaac Newton. In which sense it is that s'Gravesande calls his Elements of Physics, Introductio ad Philosophiam Newtonianam. And in this sense the *Newtonian* is the same with the new philosophy; and stands contradistinguished to the Cartesian, the Peripatetic, and the ancient corpuscular.

Others, by *Newtonian philosophy*, mean the method or order which Sir Isaac Newton observes in philosophizing, viz. the reasoning, and drawing of conclusions directly from phenomena, exclusive of all previous hypotheses; the beginning from simple principles; deducing the first powers and laws of nature from a few select phenomena, and then applying those laws, &c. to account for other things. See *Law of* NATURE. And, in this sense, the *Newtonian philosophy* is the same with the experimental philosophy; and stands opposed to the ancient corpuscular.

Others, by *Newtonian philosophy*, mean, that wherein physical bodies are considered mathematically; and where geometry and mechanics are applied to the solution of phenomena. In which sense, the *Newtonian* is the same with the mechanical and mathematical philosophy.

Others, again, by *Newtonian philosophy*, understand, that part of physical knowledge which Sir Isaac Newton has handled, improved, and demonstrated, in his Principia.

Others, lastly, by *Newtonian philosophy*, mean, the new principles which Sir Isaac Newton has brought into philosophy; the new system founded thereon; and the new solutions of phenomena thence deduced; or that which characterises, and distinguishes his philosophy from all others; which is the sense wherein we shall chiefly consider it.

As to the history of this philosophy, we have but little to say: it was first made public in the year 1686, by the author, then a fellow of Trinity college, Cambridge; and in the year 1713, republished, with considerable improvements. Several other authors have since attempted to make it plainer; by setting aside many of the more sublime mathematical researches, and substituting other more obvious reasonings, or experiments, in lieu thereof; particularly Whiston, in his Prælect. Phys. Mathemat. s'Gravesande in Element. & Inslit. and Dr. Pemberton in his View, and Maclaurin, in his excellent work, intitled, an Account of Sir Isaac Newton's Philosophical Discoveries.

Notwithstanding the great merit of this philosophy, and the universal reception it has met with at home, it gained ground, at its first publication, but slowly abroad; *Newtonianism* had scarce two or three adherents in a nation; but Cartesianism, Huygenianism, and Leibnitianism, maintained their ground, till the force of truth prevailed. And it is now held in the utmost veneration both at home and abroad.

The philosophy itself is laid down principally in the third book of the Principia. The two preceding books are taken up in preparing the way for it, and laying down such principles of mathematics as have the nearest relation to philosophy; such are the laws and conditions of powers. And these, to render them less dry and geometrical, the author illustrates by schelia in philosophy, relating chiefly to the density and resistance of bodies, the motion of light and sounds, a vacuum, &c.

In the third book he proceeds to the *philosophy* itself; and from the same principles deduces the structure of the universe, and the powers of gravity, whereby bodies tend towards the sun and planets; and from these powers, the motions of the planets and comets, the theory of the moon, and the tides.

This book, which he calls De Mundi Systemate, he tells us, was first written in the popular way; but considering, that such as are unacquainted with the said principles, would not conceive the force of the consequences, nor be induced to lay aside their ancient prejudices; for this reason, and to prevent the thing from being in continual dispute, he afterwards digested the sum of that book into propositions, in the mathematical manner; so as it might only come to be read by such as had first considered the principles; not that it is necessary a man should master them all; many of them, even the brightest mathematicians, would find a difficulty in getting over. It is enough to have read the definitions, laws of motion, and the three first sections of the first book; after which, the author himself directs us to pass on to the book De Systemate Mundi.

The several articles of this *philosophy* are delivered under their respective heads; as SUN, MOON, PLANET, COMET, ETHER, AIR, CENTRIPETAL *force*, RESISTANCE, MEDIUM, MATTER, SPACE, ELASTICITY, GRAVITY, &c. A general idea, or abstract of the whole, we shall here lay before the reader, to shew in what relation the several parts stand to each other.

The great principle on which the whole philosophy is founded, is the power of gravity. This principle is not new: Kepler, long ago, hinted it in his Introduct. ad Mot. Martis. He even discovered some of the properties thereof, and their effects in the primary planets; but the glory of bringing it to a physical demonstration was reserved to the English philosopher. See GRAVITY.

His proof of the principle from phenomena, together with the application of the same principle to the various other appearances of nature, or the deducing those appearances from that principle, constitute the *Newtonian* system; which, drawn in miniature, will stand thus:

I. The phenomena are, 1. That the satellites of Jupiter do, by radii drawn to the center of the planet, describe areas proportional to their times; and that their periodical times are in a sesquiplicate ratio of their distances from its centre. 2. That the observations of all astronomers agree. 2. The same phenomenon holds of the satellites of Saturn, with regard to Saturn; and of the moon with regard to the earth. 3. The periodical times of the primary planets about the sun are in a sesquiplicate ratio of their mean distances from the sun. But, 4. The primary planets do not describe areas any way proportional to their periodical times, about the earth; as being sometimes seen stationary, and sometimes retrograde with regard to it.

II. 1. The powers whereby the satellites of Jupiter are constantly drawn out of their rectilinear course, and retained in their orbits, do respect the center of Jupiter, and are reciprocally as the squares of their distances from the same center. 2. The same holds of the satellites of Saturn

Saturn with regard to Saturn; of the moon with regard to the earth; and of the primary planets with regard to the ſun.

III. The moon gravitates towards the earth, and by the power of that gravity is retained in her orbit; and the ſame holds of the other ſatellites with reſpect to their primary planets; and of the primaries with reſpect to the ſun. See GRAVITY, and MOON.

As to the other ſecondary planets, their phenomena, with reſpect to their primary ones, being of the ſame kind with thoſe of the moon about the earth, it is argued by analogy, that they depend on the ſame cauſes; it being a rule or axiom which all philoſophers agree to, that effects of the ſame kind have the ſame cauſes. Again, attraction is always mutual, i. e. the reaction is equal to the action: conſequently, the primitive planets gravitate towards their ſecondary ones; the earth towards the moon, and the ſun towards them all. And this gravity, with regard to each ſeveral planet, is reciprocally as the ſquare of its diſtance from its center of gravity.

IV. All bodies gravitate towards all the planets; and their weights towards any one planet, at equal diſtances from the center of the planet, are proportional to the quantity of matter in each.

For the law of the deſcent of heavy bodies towards the earth, ſetting aſide their unequal retardation from the reſiſtance of the air, is this, that all bodies fall equally in equal times; but the nature of gravity or weight, no doubt, is the ſame on the other planets, as on the earth. Suppoſe, e. gr. ſuch bodies raiſed to the ſurface of the moon, and together with the moon deprived at once of all progreſſive motion, and dropped towards the earth; it is ſhewn, that in equal times they would deſcribe equal ſpaces with the moon; and, therefore, that their quantity of matter is to that of the moon, as their weights to its weight. Add, that ſince Jupiter's ſatellites revolve in times that are in a ſeſquiplicate ratio of their diſtances from the center of Jupiter, and conſequently at equal diſtances from Jupiter, their accelerating gravities are equal; therefore, falling equal altitudes in equal times, they will deſcribe equal ſpaces, juſt as heavy bodies do on our earth. And the ſame argument will hold of the primary planets with regard to the ſun. And the powers whereby unequal bodies are equally accelerated, are as the bodies; i. e. the weights are as the quantities of matter in the planets. And the weights of the primary and ſecondary planets towards the ſun are as the quantities of matter in the planets and ſatellites. And hence are ſeveral corollaries drawn reſulting to the weights of bodies on the ſurface of the earth, magnetiſm, and the exiſtence of a vacuum; which ſee under VACUUM, WEIGHT, and MAGNETISM.

V. Gravity extends itſelf towards all bodies, and is in proportion to the quantity of matter in each.

That all the planets gravitate towards each other, has been already ſhewn; likewiſe, that the gravity towards any one, conſidered apart, is reciprocally as the ſquare of its diſtance from the center of the planet: conſequently, gravity is proportional to the matter therein. Farther, as all the parts of any planet, A, gravitate towards another planet, B; and the gravity of any part is to the gravity of the whole, as the matter of the part to the matter of the whole; and reaction equal to action; the planet B will gravitate towards all the parts of the planet A; and its gravity towards any part will be to its gravity towards the whole, as the matter of the part to the matter of the whole.

Hence we derive methods of finding and comparing the gravities of bodies towards different planets; of finding the quantities of matter in the ſeveral planets, and their denſities; ſince the weights of equal bodies revolving about planets are as the diameters of their orbits, directly; and as the ſquares of the periodical times, inverſly; and the weights at any diſtance from the center of the planet are greater or leſs in a duplicate ratio of their diſtances, inverſly; and ſince the quantities of matter in the planets are as their powers at equal diſtances from their centers: and, laſtly, ſince the weights of equal and homogeneous bodies towards homogeneous ſpheres are, at the ſurface of the ſpheres, as the diameters of thoſe ſpheres; and conſequently, the denſities of heterogeneous bodies are as the weights at the diſtances of the diameters of the ſpheres.

VI. The common center of gravity of the ſun, and all the planets, is at reſt; and the ſun, though always in motion, yet never recedes far from the common center of all the planets.

For the matter in the ſun being to that in Jupiter as 1033 to 1; and Jupiter's diſtance from the ſun to the ſemidiameter of the ſun in a ratio ſomewhat bigger; the common center of gravity of Jupiter, and the ſun, will be found a point a little without the ſun's ſurface. And, by the ſame means, the common center of Saturn and the ſun will be found a point a little within the ſun's ſurface; and the common center of the earth, and all the planets, will be ſcarce one diameter of the ſun diſtant from the center thereof. But the center is always at reſt: therefore, though the ſun will have a motion this and that way, according to the various ſituations of the planets, yet it can never recede far from the center. So that the common center of gravity of the earth, ſun, and planets, may be eſteemed the center of the whole world.

VII. The planets move in ellipſes that have their foci in the center of the ſun, and deſcribe areas proportional to their times.

This we have already laid down *à poſteriori*, as a phenomenon; and now, that the principle of the heavenly motions is ſhewn, we deduce it therefrom *à priori*. Thus, ſince the weights of the planets towards the ſun are reciprocally as the ſquares of the diſtances from the center of the ſun; if the ſun were at reſt, and the other planets did not act on each other, their orbits would be elliptical, having the ſun in their common umbilicus, and they would deſcribe areas proportional to the times; but the mutual actions of the planets are very ſmall, and may be well thrown aſide. Therefore, &c.

Indeed, the action of Jupiter on Saturn is of ſome conſequence; and hence, according to the different ſituations and diſtances of thoſe two planets, their orbits will be a little diſturbed.

The ſun's orbit too is ſenſibly diſturbed by the action of the moon; and the common center of the two deſcribes an ellipſis round the ſun placed in the umbilicus; and with a radius drawn to the center of the ſun, deſcribes areas proportional to the times.

VIII. The aphelia and nodes of the planets are at reſt; excepting for ſome inconſiderable irregularities ariſing from the actions of the revolving planets and comets. Conſequently, as the fixed ſtars retain their poſition to the aphelia and nodes, they, too, are at reſt.

IX. The axis, or polar diameter, of the planets is leſs than the equatorial diameter.

The planets, had they no diurnal rotation, would be ſpheres, as having an equal gravity on every ſide; but, by this rotation, the parts receding from the axis endeavour to riſe towards the equator, which, if the matter they conſiſt of be fluid, will be affected very ſenſibly. Accordingly Jupiter, whoſe denſity is found not ſo much to exceed that of water on our globe, is obſerved by the aſtronomers to be conſiderably leſs between the poles, than from eaſt to weſt. And on the ſame principle, unleſs our earth were higher at the equator than towards the poles, the ſea would riſe under the equator, and overflow all near it.

But this figure of the earth Sir Iſaac Newton proves likewiſe *à poſteriori*; from the oſcillations of pendulums being ſlower, and ſmaller, in the equatorial, than the polar parts of the globe.

X. All the moon's motions, and all the inequalities in thoſe motions, follow from theſe principles: e. gr. her unequal velocity, and that of her nodes, and apogee in the ſyzygies and quadratures; the differences in her eccentricity, and her variation, &c. See MOON, QUADRATURE, SYZYGY, &c.

XI. From the inequalities in the lunar motions, we can deduce the ſeveral inequalities in the motions of the ſatellites.

XII. From theſe principles, particularly the action of the ſun and moon upon the earth, it follows, that we muſt have TIDES; or that the ſea muſt ſwell and ſubſide twice every day.

XIII. Hence likewiſe follows the whole theory of COMETS; as, that they are above the region of the moon, and in the planetary ſpaces; that they ſhine by the ſun's light reflected from them; that they move in conic ſections, whoſe umbilici are in the center of the ſun; and by radii drawn to the ſun, deſcribe areas proportional to the times; that their orbits, or trajectories, are very near parabolas; that their bodies are ſolid, compact, &c. like thoſe of the planets, and muſt therefore acquire an immenſe heat in their perihelia; that their tails are exhalations ariſing from them, and encompaſſing them like atmoſpheres.

The objections raiſed againſt this philoſophy are chiefly aimed at the principle, gravity; which ſome condemn as an *occult quality*; and others as a *miraculous* and preternatural cauſe; neither of which have any longer room in ſound philoſophy. Others, again, ſet it aſide, as deſtroying the notion of vortices; and others, as ſuppoſing a vacuum. But theſe are all abundantly obviated under GRAVITY, ATTRACTION, VORTEX, VACUUM, and QUALITY.

NEXI, among the Romans, perſons free-born, who, for debt, were delivered bound to their creditor, and obliged to ſerve him, till they could pay the debt.

NEXT *taker*, among *Miners*, is he that hath the next meer in poſſeſſion.

NEXUS *of matter*. See COHESION.

NHAMBUGUACU, in *Botany*, a name of the great American *vicinus*, or *palma Chriſti*.

NHAMDIA, in *Ichthyology*, the name of a fiſh caught in the rivers of many parts of America, and of a fine taſte. It is of the anguilliform kind, and has a long and fat body, becoming ſmaller toward the tail; its belly is ſoft; its head flat; and its mouth of a parabolic figure, and armed with ſmall teeth; it is uſually of about eight or ten inches long; its tail is forked, and its head is covered with a ſtrong ſhelly coat; this is of a duſky brown; its back and ſides are of a bluiſh grey; the larger back-fin is of the ſame colour; all the reſt are black; and on each ſide there is a red line reaching lengthways from the gills to the tail.

NHANDIROBA, in *Botany*, a name given by Plumier to a genus of plants, the ſame with the PEVILLEA of Linnæus.

NHANDUAPOA, the name of a Braſilian bird, called alſo *jabirunacu*, but more frequently known by its Dutch name SCURVOGEL.

NHANDUGUACU, in *Ornithology*, the name of a Braſilian bird of the emeu, or caſſowary kind, a ſpecies of the *ſtruthia*, or OSTRICH, in the Linnæan ſyſtem, but ſmaller than the common or African caſſowary. Its body is conſiderably large; its neck long and ſtrong; its legs very long and thick; its wings extremely ſhort, and unfit for flying, but aſſiſting it in running; its feathers are grey, and, on the back, are conſiderably long; it commonly carries its neck bent like a ſwan; its head is ſhaped like that of a gooſe; its back feathers cover the rump, and make a ſort of tail; it runs as ſwift as a greyhound, and feeds on fleſh and fruits.

NHAQUUNDA, in *Ichthyology*, the name of a ſmall fiſh caught in the American rivers. Its body is oblong, and every where nearly of the ſame thickneſs; its head and mouth are like thoſe of the pike; and its uſual length is about four inches; it can extend its upper lip, and round the opening of its mouth; it has no regular teeth, but its jaws are rough like a file; its tail is covered with a hard ſhelly cruſt; its body is covered with moderately large ſcales, and its back and ſides are of a ſilvery grey; its belly white; it has on each ſide a ſingle row of round black ſpots, of the bigneſs of a pea, and among theſe a number of ſmall blue ones.

NIAGARA, in *Geography*, a prodigious cataract in Canada, in North America, between the lakes Erie and Ontario, where the water falls from high rocks a hundred and thirty-ſeven feet high, and half a league broad; the water runs to it with ſuch violence, that all the beaſts that attempt to croſs it a quarter of a league above, are ſwallowed up; and it tumbles off the precipice with ſuch fury, that it makes an arch under which ſhrce men may paſs abreaſt without danger or damage, except a few drops of water falling upon them. The miſt which this fall occaſions may be ſeen at fifteen miles diſtance, ariſing as high as the clouds, and forming a beautiful rainbow. See CATARACT.

NICENE *creed*. See CREED.

NICETERIA *Athenæ*, NIKETERIA *Athenæ*, in *Antiquity*, an Athenian ſolemnity in memory of Minerva's victory over Neptune, when they contended which of them ſhould have the honour of giving a name to the city afterwards called Athens.

NICHE, in *Architecture*, a cavity, or hollow place, in the thickneſs of a wall, to place a figure or ſtatue in.

The word comes from the Italian *nicchio*, *ſhell*; becauſe the ſtatue is here incloſed in a ſhell; or, perhaps, by reaſon of the ſhell wherewith the tops of ſome of them are adorned. See *Tab. Architecture, fig. 40. lit. Z.*

Niches are made to partake of all the ſegments under a ſemicircle. They are ſometimes at an equal diſtance from the front, and are parallel or ſquare on the back with the front-line; in which caſe they are called ſquare receſſes, or ſquare *niches*.

The larger *niches* ſerve for groups of figures; the ſmall ones for ſingle ſtatues, and ſometimes only for buſts.

Great care muſt be taken to proportion the *niches* to the figures; and that the pedeſtal of the figures be proportioned to the *niches*.

Niches are ſometimes made with ruſtic-work.

NICHE, *round*, is that whoſe plan and circumference are circular.

NICHE, *ſquare*, that where they are ſquare.

NICHE, *angular*, that formed in the corner of the building.

NICHE, *ground*, that which, inſtead of bearing on a maſſive, has its riſe from the ground; as the *niches* of the portico of the Pantheon at Rome. Their ordinary proportion is to be two diameters in height, and one in width.

NICHE, *capital of a*. See CAPITAL.

NICHE, *cul de four of a*. See CUL.

NICHED *column*. See COLUMN.

NICHILIANISTÆ, in *Church Hiſtory*, heretics who maintained that Chriſt had no being.

NICHILS. See NIHILS.

NICHILS, *clerk of the*. See CLERK.

NICKAR-*tree*, in *Botany*. See GUILANDINA.

NICKEL, in *Natural Hiſtory*, is a ſemi-metal, firſt deſcribed by Mr. Cronſtedt, in the Swediſh Memoirs for the years 1751 and 1754. The properties there attributed to it are, 1. That it is of a white colour, inclining to red. 2. Its texture is ſolid, and ſhining in its fractures. 3. Its ſpecific gravity is to that of water as 8000 to 1000. 4. It is conſiderably fixed in the fire. 5. It is calcinable, and its calx is green. 6. This calx is not very fuſible, but it nevertheleſs tinges glaſs of a tranſparent reddiſh brown, or jacinth colour. 7. It diſſolves in aqua fortis, aqua regia, and marine acid, but with difficulty in vitriolic acid: all theſe ſolutions have a deep green colour; the vitriol formed of it is alſo of the ſame colour; and the colcothar of this vitriol, and alſo the precipitates from the ſolutions, are rendered by calcination of a light green colour. 8. Theſe precipitates are ſoluble by ſpirit of ſal ammoniac, and the ſolution has a blue colour; but no copper can be produced by a reduction of the precipitates. 9. It ſtrongly attracts ſulphur. 10. It unites with all metallic ſubſtances, excepting ſilver, quickſilver, and zinc. 11. Its attraction to regulus of cobalt is the ſtrongeſt, next to which is that to iron, and then to arſenic. 12. It retains its phlogiſton a long time in the fire, and its calx is reducible by a very ſmall quantity of inflammable matter. It requires, however, a ſtrong red heat before it can be fuſed, and melts a little ſooner, or as ſoon as gold or copper. *Nickel* is contained in the mineral, called *Kupfer*, or KUPFER-*nickel*.

NICOL, in *Natural Hiſtory*, a word uſed by the miners in Germany to expreſs a greeniſh cruſt, covering ſeveral of the ſpecies of marcaſites and cobalt: it emits fumes that ſmell of garlic in the calcination, and is very injurious to the workmen, cauſing contractions of their limbs, and other diſorders. It is ſometimes found in maſſes alone, but that more rarely.

NICOLAI *Catholicon*. See CATHOLICON.

NICOLAS, *Saint, Argonauts of*. See ARGONAUTS.

NICOLAITANS, or NICOLAITES, one of the moſt ancient ſects in the Chriſtian church; thus denominated from Nicolas, a perſon ordained a deacon of the church of Jeruſalem, together with St. Stephen.

The diſtinguiſhing tenet of the *Nicolaitans*, as repreſented by eccleſiaſtical hiſtorians, is, that all married women ſhould be common; to take away all occaſion of jealouſy.

Other authors tax Nicolas with other impurities; but Clemens Alexandrinus imputes them all to his diſciples, who, he ſays, abuſed their maſter's words.

In the charge urged againſt the *Nicolaitans* (Rev. ii. 6, 14, 15,) they are not reproached with erroneous opinions concerning the Deity, but with the licentiouſneſs of their practice, and the contempt of that ſolemn law, which the apoſtles had enacted, (Acts xv. 29.) againſt fornication, and the uſe of meats offered to idols. It is, however, certain, that the writers of the ſecond and the following centuries, Irenæus, Tertullian, Clemens, and others, affirm, that the *Nicolaitans* adopted the ſentiments of the GNOSTICS, concerning the two principles of all things, the æons, and the origin of this terreſtrial globe.

The authority of theſe writers, ſays Moſheim, would be entirely ſatisfactory in this matter, were there not ſome reaſon to imagine, that they confounded, in their narrations, two ſects very different from each other, viz. that of the *Nicolaitans*, mentioned in the Revelations; and another, founded by a perſon named Nicolaus, in the ſecond century, upon the principles of the Gnoſtics Cerdon, Holleman, Vitringa, and Mauis, take the name *Nicolaitan* to be coined, to ſignify a man addicted to pleaſure and debauchery; adding, that it has nothing to do with Nicolas one of the ſeven deacons.

NICOMIA, in *Natural Hiſtory*. See CHERT.

NICOTIANA, or *herba Nicotiana*, a name given to TOBACCO; from Nicot, the French ambaſſador, at the court of Portugal, who ſent it into France, in 1560, and gave it his own name, as he himſelf tells us in his dictionary.

NICTITATING *membrane*, in *Anatomy*, a thin membrane, which covers the eyes of ſeveral creatures, and ſhelters them from duſt, or too much light; yet is ſo thin, that they can ſee indifferently well through it.

This *nictitating membrane* is chiefly found in the bird and fiſh kind.

This membrane, in the eagle's eye, is remarkably cloſe and firm, inſomuch as to be accounted as a ſecond eye-lid;

lid: and hence that remarkable firmneſs of the eagle's ſight in viewing the ſun.

NIDDUI, in the *Jewiſh Cuſtoms*, is uſed to ſignify ſeparated or excommunicated. This, according to ſome, was to be underſtood of the leſſer ſort of excommunication in uſe among the Hebrews. He that had incurred it was to withdraw himſelf from his relations, at leaſt to the diſtance of four cubits: it commonly continued a month. If it was not taken off in that time, it might be prolonged for ſixty, or even ninety days: but if, within this term, the excommunicated perſon did not give ſatisfaction, he fell into the *cherem*, which was a ſecond ſort of excommunication; and thence into the third ſort called *ſhammatha*, or *ſhemata*, the moſt terrible of all. But Selden has proved that there were only two kinds of excommunication, viz. the greater and leſs; and that theſe three terms were uſed indifferently.

NIDUS, *neſt*, a repoſitory, wherein certain animals, particularly fowls, inſects, and reptiles, lodge their eggs, for incubation; and wherein, when hatched, they nurſe their young, till they become able to ſhift for themſelves. The word is Latin, and is ſuppoſed to be derived from *nidor*, *a rank or ill ſmell*; in regard the neſts of animals uſually ſtink.

Mr. Derham ſays, he has often wondered how waſps, hornets, and other inſects, that gather dry materials (as the duſt of wood ſcraped for that purpoſe), ſhould find a proper glutinous matter to cement and glue their combs, and line their cells: but he adds, that, in all probability, it is in their own bodies; as in the tinea veſtivora, the cad-worm, &c.

Goedart obſerves of his eruca, that fed on leaves, that they made their cells of leaves glued together with their own ſpittle.

NIDUS *avis*, in the Linnæan ſyſtem of *Botany*, the name of a ſpecies of OSBECK.

NIECE, a term relative to uncle and aunt, ſignifying a brother's or ſiſter's daughter; which, in the civil law, is the third degree of conſanguinity; and, in the common law, the ſecond.

NIEKE *corunde*, in the language of the Ceyloneſe, the name of a ſpecies of cinnamon. The tree which produces it reſembles the *nieke*, another tree very common there. This is a very bad kind of cinnamon, and has very little taſte or ſmell. It is very ſeldom ſold as cinnamon, but is much in eſteem among the natives for its medicinal virtues. They obtain a water, and an oil from it, by roaſting, which they anoint themſelves with, to preſerve them from noxious fumes, and infections of any kind; and uſe the expreſſed juice of the leaves to cool the head, and ſtrengthen the brain, rubbing it on externally. Phil. Tranſ. N° 409.

NIENT *compoſe*, in *Law*, an exception taken to a petition, as unjuſt; becauſe the thing deſired is not in that act or deed whereon the petition is grounded.

Thus a perſon deſiring of the court to be put in poſſeſſion of a houſe formerly adjudged to him among other lands; the adverſe party pleads, that this petition is not to be granted; by reaſon though the petitioner had a judgement for certain lands and houſes, yet this houſe is *nient compriſe*, not comprized therein.

NIGELLA, in *Botany*. See FENNEL *flower*.

NIGHT, that part of the natural day, during which the ſun is underneath the horizon: or, *night* is that ſpace of time wherein the ſun is out of our hemiſphere.

Under the equator, the *nights* are always equal to the days. Under the poles, the *night* continues half a year.

The ancient Gauls and Germans divided their time not by days, but *nights*; as appears from Tacitus and Cæſar; and the people of Iceland, and the Arabs, do the ſame at this day. See DAY, HOUR, &c.

The ſame is alſo obſerved of our Saxon anceſtors.

Thus, in the council of Cloveſhoe, anno 824, we read, *Ibi ſtatuta & proſcripta contentione coram epiſcopo poſt* 30 *noctes, illum juramentum ad Weſtminſter deducturum eſt.*— Whence our cuſtom of ſaying, *ſevennight*, *fortnight*, &c.

NIGHT, *ſignals by*. See SIGNALS.

NIGHT-*crow-lyng*, *third*. See THIRD.

NIGHT-*mare*. See INCUBUS.

NIGHTSHADE, *ſolanum*, in *Botany*, a genus of the *pentandria monogynia* claſs. Its characters are theſe: the empalement of the flower is permanent of one leaf, cut half through into five acute ſegments; the flower has one wheel-ſhaped petal, having a very ſhort tube; the brim is large, ſpreading, and five-pointed; it has five awl-ſhaped ſtamina, terminated by oblong ſummits, which ſtand together; and a roundiſh germen, ſupporting a ſlender ſtyle, longer than the ſtamina, and crowned by an obtuſe ſtigma; the germen afterwards turns to a roundiſh berry, with two cells, having a convex fleſhy receptacle, filled with roundiſh compreſſed ſeeds. There are thirty-ſix ſpecies. Miller. See MAD-*apple*.

The garden *nightſhade* of the ſhops, with black berries, is annual, grows ſpontaneouſly in cultivated grounds, and flowers in Auguſt. The leaves are uſed in external applications, and are ſaid to act as refrigerants, reſolvents, and diſcutients; taken internally, in the quantity of not many grains, they are highly deleterious; in very ſmall doſes, as an infuſion in boiling water of half a grain or a grain of the dried leaves, they occaſion a warmth over the whole body, which is often followed by a ſweat, or an increaſe of the urinary diſcharge, or ſome looſe ſtools, or a ſickneſs and vomiting, and often by a head-ach, giddineſs, dimneſs of the ſight, and other paralytic ſymptoms. In ſome cancerous, ulcerous, and hydropic caſes, theſe infuſions have been repeated at bed-time, every two or three nights, or oftener, and the quantity of the leaves in each doſe increaſed gradually to five or ſix grains or more, with apparent benefit; but their operation is ſo irregular, and their effects on the nervous ſyſtem ſo alarming, that the uſe of them is juſtly laid aſide. It is obſerved, that their beneficial effects depend on the evacuations they produce; and that, when they do not act as evacuants, they generally aggravate the complaints. The roots and berries are much of the ſame nature with the leaves; though Geſner reports, that the expreſſed juice of the latter, boiled with ſugar, to the conſiſtence of a ſyrup, proves, in doſes of a teaſpoonful, an effectual and ſafe anodyne; but he cautions againſt exceeding this doſe. Lewis.

NIGHTSHADE, *American*, *phytolacca*, in *Botany*, a genus of the *decandria pentagynia* claſs. Its characters are theſe: the flower hath no empalement, according to ſome, and no petals, though the cover of the parts of generation, being coloured, is by ſome termed petals, there are five of theſe, which are concave, open, and permanent; it has for the moſt part ten ſtamina, which are of the ſame length as the petals, terminated by roundiſh ſummits, and ten compreſſed, orbicular germina, joined together on their inſide, but divided on their outſide; upon which ſit ten very ſhort ſtyles, which are reflexed; the germina afterward turn to an orbicular depreſſed berry, with ten longitudinal deep furrows, having ten cells, each containing a ſingle ſmooth ſeed. Miller reckons three, and Linnæus four ſpecies.

Parkinſon ſays, that the inhabitants of North America make uſe of the juice of the root of American *nightſhade*, with large fruit, commonly called Virginian poke, as a familiar purge; two ſpoonfuls of the juice will work ſtrongly. Of late there have been ſome quacks, who pretend to cure cancers with this herb; but no inſtance is known of its having been ſerviceable in that diſorder. The inhabitants of North America boil the young ſhoots of this plant, and eat it like ſpinach. The juice of the berries ſtains paper and linen of a beautiful purple colour, but it will not laſt long: if there could be a method of fixing the die it might be very uſeful. Miller.

NIGHTSHADE, *baſtard*. See RIVINA.

NIGHTSHADE, *climbing*, or *Malabar*. See BASELLA.

NIGHTSHADE, *deadly*, *atropa*, in *Botany*, a genus of the *pentandria monogynia* claſs. Its characters are theſe: the flower is bell-ſhaped, hath a permanent empalement of one leaf, cut into five parts, and is divided into five equal parts; it hath five ſtamina riſing from the baſe of the petal; in the center is ſituated an oval germen, which becomes a globular berry, having two cells ſitting on the empalement, and filled with kidney-ſhaped ſeeds. Miller reckons two and Linnæus five ſpecies.

This plant ſhould not be ſuffered to grow in any places where children reſort, for it is a ſtrong poiſon; ſeveral inſtances having happened where children have been killed by eating the berries.

There is a remarkable inſtance of the direful effects of this plant, recorded in Buchanan's Hiſtory of Scotland; wherein he gives an account of the deſtruction of the army of Sweno, when he invaded Scotland, by mixing a quantity of the juice of theſe berries with the drink, which the Scots, by their truce, were to ſupply them with: this ſo intoxicated the Danes, that the Scots fell upon them, in their ſleep, and killed the greateſt part of them; ſo that there were ſcarcely men enough left to carry off their king. See, on this article, Phil. Tranſ. vol. lx. part i. p. 62.

NIGHTSHADE, *enchanter's*, *circæa*, in *Botany*, a genus of the *octandria monogynia* claſs. Its characters are theſe: the flower hath a double-leaved empalement and two heart-ſhaped petals, and has two erect hairy ſtamina; the germen is ſituated under the flower, and the empalement becomes an oval capſule, with two cells opening lengthways, each containing a ſingle oblong ſeed. There are two ſpecies.

NIGHTSHADE, *three-leaved*. See *Herb* PARIS *of Canada*.

NIGHTSHADE, *Virginian*. See *American* NIGHTSHADE.

NIGHTSHADE, *woody*, called *bitter-ſweet*, *dulcamara*, and

amara

amara dulcis, is a species of *solanum*, which grows by the side of hedges, and in moist ditches, climbing upon the bushes with winding, woody, but brittle stalks. It is perennial, and flowers in June and July. The roots and stalks of this species, which, on first chewing them, yield a considerable bitterness, that is soon followed by an almost honey-like sweetness, have been commended in different disorders, as high resolvents and deobstruents. Their sensible operation is by sweat, urine, and stool: the dose from four to six ounces of a tincture made by digesting four ounces of the twigs, in a quart of white wine.

Experience, says Dr. Lewis, has shewn, that they are by no means equally deleterious with deadly *nightshades*; that they act more regularly and uniformly; and that, without producing nervous complaints, they produce more considerable evacuations, especially by stool: but, he adds, that their virtues, in particular cases, have not yet been sufficiently ascertained. Mat. Med.

NIGHTINGALE, *luscinia* or *philomela*, in *Ornithology*, the brownith grey *motacilla*, with the annules of the knees grey.

The *nightingale* derives its name from *night* and the Saxon word *galan*, *to sing*. It is in size equal to the red-start; but longer bodied and more elegantly made. The head and back are a pale tawny, dashed with olive; the tail is of a deep tawny red; the throat, breast, and upper part of the belly of a light glossy ash-colour; the lower belly almost white; the exterior webs of the quill-feathers are of a dull reddish-brown; the interior of brownish ash-colour; the insides are hazel; the eyes remarkably large and piercing; and the legs and feet of a deep ash-colour.

Mr. Hunter found, by dissection, that the muscles of the larynx are stronger in the *nightingale*, than in any other bird of the same size.

This bird, the most famed of the feathered tribe, for the variety, length, and sweetness of its notes, visits England in the beginning of April, and leaves us in August; and during its continuance with us, its range is confined to a part of this island: it is not found in Scotland, Ireland, or North-Wales, nor in any of the northern counties, except Yorkshire: and it does not migrate so far to the West as Devonshire and Cornwall. *Nightingales* form their nests of oak leaves, a few bents, and reeds. The eggs are of a deep brown. They begin their song in the evening and continue it the whole night. Pennant.

NIGHTINGALE, *Virginian*, in *Ornithology*, the common, but improper name of a bird of the gross-beaked kind, called by authors *fringilla cucullo nuchâ cristâ Indica cristata*.

It is a little smaller than our blackbird; it has a black ring, surrounding the eyes and nostrils; the beak is very large and thick, but not altogether so large as in the common gross-beak; and its head is ornamented with a very high and beautiful creft, which it moves about very frequently; it is all over of a very fine, and lively red, but paler on the head and tail than elsewhere; it is brought to us from Virginia, and is much valued in England, for its beauty, and delicate manner of singing; it is very fond of almonds and the like fruits.

NIGHTINGALE, *wood*. See BLACK-CAP.

NIGHTWALKERS, in a legal sense, are such persons as sleep by day and walk by night, being oftentimes pilferers or disturbers of the peace.

5 Ed. III. cap. 14. Constables are authorized by the common law, to arrest *nightwalkers*, and suspicious persons, &c. Watchmen may also arrest *nightwalkers*, and hold them until morning: and, it is said, that a private person may arrest any suspicious *nightwalker*, and detain him till he give a good account of himself. 2 Hawk. P. C. 61. 80. One may be bound to the good behaviour for being a *nightwalker*; and common *nightwalkers* and haunters of bawdy-houses are to be indicted before justices of peace, &c. But it is held not lawful for constable, &c. to take up any woman, as a *nightwalker*, on bare suspicion only of being of ill fame, unless she be guilty of a breach of the peace, or some other unlawful act.

NIGHTWALKERS, in a physical sense. See NOCTAMBULATIO.

NIGRINA, in *Botany*, a genus of the *pentandria monogynia* class. Its characters are that the flower is funnel-shaped, the empalement is inflated, the stigma is obtuse, and the fruit is a double celled capsule. There is only one species.

NIGRITIES *ferri*, among the ancients. See CARIES.

NIHIL, *nihilum*, *nothing*, among the school philosophers, is what has no real effe, and which is only conceived negatively, and denominated by a negative.

NIHIL *capiat per billam*, or *per breve*, in *Law*, is a form used when judgment is given against the plaintiff, to bar his action, or overthrow his writ or bill.

NIHIL or NIL *debet*, is the usual plea in an action of debt; but it is no plea in an action of covenant, or breach assigned for non-payment of rent, &c.

NIHIL *dicit* is a failing of a defendant to put in an answer to the plaintiff's plea by the day assigned; on which omission judgment is given against him of course, *quod nihil dicit*, because he alledges nothing to the contrary.

NIHIL or NIHILI *album*. See POMPHOLYX.

NIHILS, or NICHILS, issues which the sheriff, that is appointed in the exchequer, says are nothing worth, and ileviable; from the insufficiency of the parties that should pay them.

NIHILS, *clerk of the*, *nihilorum clericus*. See CLERK and EXCHEQUER.

NIL, in *Botany*, a name given by the Arabians to two very different seeds, which are often, by this means, mistaken in their writings, one for another. Avicenna tells us first that *nil* is the seed of a creeping plant, of the bind-weed kind, and that this plant had blue flowers, like the campanulæ, or bell flowers: but, in another place, he tells us, that *nil* is the name of a plant used in dying, which seems to be the same with our *isatis*, or woad.

It is probable, that the convolvulus, or bind-weed, called *nil*, obtained this name only from its flowers being of the same colour with the fine blue pigment obtained from the other *nil*, or woad.

NIL *habuit in tenementis*, in *Law*, a plea to be brought in an action of debt only, brought by a lessor against a lessee, for years, or at will, without deed.

NILACUNDI, in *Natural History*, a name given to a stone of the gem kind, which is half a SAPPHIRE and half a RUBY.

The word *nilla* is the Indian name for the sapphire, derived from the word *nil*, the name of indigo, and given to this gem because of its fine blue colour, which approaches to the tinge of that pigment. The latter part of the word is not easily accounted for, without making a little variation in the spelling, but with that, is very clear and easy. *Jaun*, or *jaunti*, and, as some speak it, *jacunti*, is the name given by the Indians to the ruby, and it is only supposing the word to be properly *nillacunti*, and it expresses, in their own language, exactly what we understand by it, a stone, part sapphire and part ruby.

NILAHUMATU, in *Botany*, a name given by several authors to the smooth-fruited HYRAMONIUM of Malabar.

NILIACUM *mel*, a name by which the ancients expressed the very finest honey.

NILICANARAM, in *Botany*, the name by which some authors call the tree whose fruit is the myrobalan used in medicine.

NILOMETER, or NILOSCOPE, an instrument used among the ancients, to measure the height of the water of the river Nile, in its overflowings.

The word comes from Νειλος, *Nile* (and that from νεα, *nea*, *new mud*, or, as some others will have it, from νειν, *I flow*, and ιλυς, *mud*), and μετρον, *measure*. The Greeks more ordinarily call it Νειλοσκοπιον.

The *nilometer* is said, by several Arabian writers, to have been first set up, for this purpose, by Joseph, during his regency in Egypt: the measure of it was fifteen cubits, this being the height of the increase of the Nile, which was necessary to the fruitfulness of Egypt.

From the measure of this column, Dr. Cumberland deduces an argument, in order to prove that the Jewish and Egyptian cubit were of the same length. Scripture Weights and Measures, p. 18.

In the French king's library is an Arabic treatise on *Nilometers*, intitled, Neil fi alnal al Nil; wherein are described all the overflowings of the Nile, from the first year of the Hegira to the 875th.

Herodotus mentions a column erected in a point of the island Delta, to serve as a *Nilometer*; and there is still one of the same kind in a mosque of the same place.

As all the riches of Egypt arise from the inundations of the Nile, the Egyptians used to supplicate them at the hands of their Serapis; and committed the most execrable crimes, sacrifices, forfeits, of religion, to obtain the favour. This occasioned Constantine expressly to prohibit these sacrifices, &c. and to order the *Nilometer* to be removed into the church; whereas, till that time, it had been in the temple of Serapis. Julian the Apostate had it replaced in the temple, where it continued till the time of the great Theodosius. See, on the subject of *Nilometers*, the *Acta Eruditorum* Lipsiæ anno 1688, p. 147.

NILUFAR, in *Botany*, a name given by the ancient writers to the common *water-lily*. They distinguished this plant by that name from the Indian *nymphæa*, whose root was of a cold and soporific virtue, like that of the mandrake. This they call always *nenufar*.

NIMBUS, among the Romans, a scarf embroidered with gold, which women wore on their foreheads.

NIMBUS was likewise used for the money thrown among the people, on any public occasion.

NIMBUS, in *Antiquity*, a circle observed on certain medals, around the heads of some emperors; answering to the areolæ, or circles of light, drawn around the images of saints.

The *nimbus* is seen on the medals of Maurice, Phocas, and others even of the upper empire.

NIMETULAHITES, a kind of religious among the Turks; so called from *Nimetulahi*, their institutor.

When a Turk would be admitted into the order, he is to shut himself up close in a chamber forty days, restricted to four ounces of food per day. The term expired, the *Nimetulahites* take him by the hand, and lead him a Moorish dance, accompanied with an infinity of ridiculous gesticulations, till the violence of the exercise, with his former regimen, throw him down on the ground. This fall is construed an extacy, during which he is supposed to have a vision.

The *Nimetulahites* meet every Monday in the night-time, and sing hymns to God, &c.

NIN-O, in *Chronology*, is the name of the æra most commonly used among the Japanese. It commences with the reign of Sin-mu, the founder of their monarchy, 660 years before the Christian æra.

NINSI, in *Botany*. See GIN-SENG.

NINTH, in *Music*, one of the dissonant intervals in music. It is properly the second doubled; but it is differently used. When an upper part syncopates, the second is accented, and treated as a *ninth*; i.e. it is resolved by an eighth, and accompanied by a third and fifth, and often a syncopated seventh: but when the lower part syncopates, the second is not thus used, but is accompanied by the fourth and sixth. In thorough bass, as the *ninth* has always, or at least commonly, an eight placed after it thus, 9 8, to shew that that is resolved by descending to the octave.

NINTH *pair of nerves*. See NERVES.

NINTIPOLONG, in *Zoology*, the Ceylonese name of a species of serpent called also *serpens tupuoticus*. It is a very poisonous species, and its bite brings a sleep upon the person, which terminates in death. It is of a deep, blackish brown, variegated with small specks of white.

NINZIN, in the *Materia Medica*, a name used by some authors for the famous Chinese root, commonly called GINSENG.

NIPPERS, in the *Manege*, are four teeth in the forepart of a horse's mouth, two in the upper, and two in the lower jaw. A horse puts them forth between the second and third year.

NIPPERS is also an instrument in use among smiths, and farriers, being a kind of pincers, wherewith, in shoeing a horse, they cut the nails before they rivet them. It is also used in taking off a shoe.

NIPPERS, in a ship, are pieces of flat braided cordage, used to fasten the cable to the voyal, in a ship of war, when the former is drawn into the ship, by mechanical powers applied to the latter. These *nippers* are usually six or eight feet in length, according to the size of the cable: and five or six of them are commonly fastened about the cable and voyal at once, in order to be heaved in by the capstern. Those which are farthest aft are always taken off, as the cable approaches the main hatchway; and others are at the same time fastened on, in the fore part of the ship, to supply their place. The persons employed to bind the *nippers* about the cable and voyal, are called *nipper*-men: they are assisted, at this office, by the boys of the ship, who always supply them with *nippers*, and receive the ends of those which are fastened, to walk aft with them, and take them off at the proper place, in order to return them to the *nipper*-men. Falconer.

NIPPLE, *papilla*, in *Anatomy*, a prominence arising from the middle of the breast or mamma. See BREAST.

The colour of the *nipple* is various; in different states, and stages of life it is reddish, bluish, and blackish; it is encompassed with a pale brownish or reddish circle, called *areola*.

The lacteal tubes, coming from the several parts of the breasts, terminate in the papillæ, with several nervous, or spongious emissaries which communicate with each other by anastomosis, through which, in sucking, the milk is drawn.

The *nipples* of women, in their first lying in, are frequently so small, and sunk into their breasts, that the infant cannot get at them to suck its nourishment. The readiest method, in this case, is to apply an infant somewhat older, and which can draw stronger; or, if this does not succeed, to let a woman, who has been practised in the art, attempt to suck.

When these do not succeed, it is common to have recourse to a glass pipe, and the poorer people in some places usually make a tobacco-pipe serve the turn. Others apply a small cucurbite, made of ivory, in the form of a hat, which they suck strongly in their mouth. The common sucking-glass is also, when properly applied, of very signal service. To do this, the small hole at the side is to be stopped with wax, and the glass heated with warm water; or, by holding it before the fire, so as to rarefy, and in part, expel the air: it is then to be applied to the *nipple*, which, in this case, will not only be pulled out, but will discharge a large quantity of milk, so as to take down the inflammation and tumor in the breast. When the sucking power of the glass is grown weak, the hole at the side is to be opened, and the milk poured out; the glass is then to be heated again, and the hole being stopped again, it is to be a second time applied, and so on, till the intention is fully answered. Heister's Surgery, part ii. p. 11.

NIPPLE-*wort*, *lapsana*, in *Botany*, a genus of the *syngenesia polygamia æqualis* class. Its characters are these: the flower is composed of several hermaphrodite florets, included in one common imbricated empalement; the flowers have one tubulous petal, stretched out at the top, in shape of a tongue; these have each five short hairy stamina; the germen is situated at the bottom of the flower, which afterward becomes an oblong three-cornered seed, situated in the scale of the empalement. There are four species. Miller.

The common *nipple-wort*, which is a weed, growing by the side of foot-paths and hedges, is esteemed excellent for curing ulcerated nipples, whence it obtained its name. It is said to be drying, detergent, and digestive. The leaves and stalks may be boiled and eaten. James.

NIQUI, in *Ichthyology*, the name of a fish of the cucullus kind, approaching to the figure of that species commonly called *ocrace*, and *araneus marinus*, and in English the *weever*. It is common about the American shores, and is eatable when the liver and gall are taken out, otherwise it is said to be poisonous. See *Trans.* III. *of Essays*, N° 29.

NIR, in the *Materia Medica*, a name given by the Arabian physicians to the pigment, or colour, made from the *glastum*, or woad.

NISAN, a month of the Hebrews, answering to our March, and which sometimes takes from February, or April, according to the course of the moon. It was made the first month of the sacred year, at the coming out of Egypt. *This month shall be unto you the beginning of months, it shall be the first month of the year to you.* Exod. xii. 2. It was the seventh month of the civil year. Moses calls it *Abib*. The name *Nisan* is only since the time of Ezra, and the return from the captivity of Babylon.

NISI PRIUS, in *Law*, a judicial writ, which lieth in cases where the jury being impanelled and returned before the justices of the bench, one of the parties requests to have such writ, for the ease of the county, whereby to will the sheriff to cause the inquest to come before the justices in the same county, at their coming thither.

It is called a writ of *nisi prius*: and its effect is, that the sheriff is hereby commanded to bring to Westminster the men impannelled, at a certain day, before the justices, *nisi prius justiciarii domini regis ad assisas capiendas venerint*; that is, unless the justices go before that day, into such county to take assises. This they are sure to do, in the variations preceding each Easter and Michaelmas terms, and there dispose of the cause; which saves much expence and trouble to the parties, the jury, and the witnesses.

NISI PRIUS and *assise, courts of*, are composed of two or more commissioners, who are twice in every year sent by the king's special commission, all round the kingdom (except only London and Middlesex, where courts of *nisi prius* are holden in and after every term, before the chief or other judge of the several superior courts), to try, by a jury of the respective counties, the truth of such matters of fact as are then under dispute in the courts of Westminster-hall.

NISI PRIUS, *justices of*. See JUSTICES.

NISSOLIA, in *Botany*, a genus of the *diadelphia decandria* class. Its characters are, that the calyx is divided into five segments, and that the fruit is a monospermous capsule. There are two species.

NISUS, in *Ornithology*, a name by which many authors call the *accipiter fringillarius*, or *sparrow*-HAWK.

NISUS is also a name used by some old naturalists for the HALIAETUS, or *aquila marina*, called in English the *sea*-EAGLE, or *osprey*.

NISUS is likewise a name given by the barbarous writers of the middle ages to *dialophus*.

NITEDULA, in *Zoology*, the field-mouse. See MUS.

NITIDUM *folium*, among *Botanists*. See LEAF.

NITRARIA, in *Botany*, a genus of the *dodecandria monogynia* class. Its characters are, that the flower has five petals; the empalement is divided into five segments; the stamina are fifteen; and the fruit is a monospermous drupe. There is only one species.

NITRE, *nitrum*, in *Natural History*, a bitter sort of salt, thus called by the ancients; by the moderns, more usually, *saltpetre*.

Naturaliſts differ as to the point, whether our ſaltpetre be the *nitre* of the ancients; but it certainly is not.—G. C. Schelhammer has a particular treatiſe on this ſubject, De *Nitro*, tum veterum, tum noſtro, Commentarius. See NATRON.

NITRE, or SALTPETRE, is a neutral ſalt, compoſed of nitrous acid, ſaturated with fixed vegetable alkali. It is found immerſed in imperceptible particles, in earthy ſubſtances, as the particles of metals in their ores, and is diſcoverable in theſe bodies by an acrid and pungent taſte, and a ſenſation of coldneſs with which it affects the tongue: ſometimes alſo it is found native and pure, in form of an efflorefcence, or ſhapeleſs ſalt, either in its ore, or on old walls, and yields after ſolution hexaedral priſmatic cryſtals.

Nitre is found naturally cryſtallized in India, and as it is ſwept from earths or ſtones with brooms, it is called the ſweepings of *nitre*, or of ſaltpetre. A *nitre* may alſo be obtained from ſeveral plants: and theſe are the two kinds of natural *nitre*. All other *nitre* is begun by nature but art is required to extract and purify it.

Many have been of opinion, that *nitre* was, in part at leaſt, an animal ſalt, and that where it was found on old walls, it was owing to the effluvia of animal bodies once inhabiting the place; but we find it now in vaſt quantities in ſeveral of the marly earths of the Eaſt Indies, and ſome other places, which, however, though they abound with it, when they are in the naked cliffs, expoſed to the air, in a proper ſituation, yet when dug up from any depths in the earth, the ſame ſubſtances are not found to contain any of this ſalt.

This marly earth is frequent in China, Perſia, and many parts of the Eaſt, and is choſen for working from places where it ſtands in barren cliffs, on hills facing the northern or eaſtern winds. The manner of their ſeparating *nitre* from this earth, is as follows: they dig large pits, which they coat over on the inſide with a ſtiff and firm clay; this they fill half full of water, and into it throw the earth. When the water has ſtood ſome days to imbibe the ſalt, they draw it off into other pits, defended by ſlight walls on all but the north-eaſt ſide. Here the ſun exhaling the water, the ſalt which it had imbibed aſſixes itſelf to the ſides of the pit in ſmall, brownith, white, hexaedral, but very imperfect cryſtals, which are what we receive from the Eaſt Indies, under the name of rough *nitre*.

This is the way the greateſt quantity of this ſalt is made, but it is alſo procured from divers other materials, and by many other methods.

The method of manufacturing ſaltpetre in Podolia, related by Dr. Wolf, is as follows: the earth or mould, which they make uſe of for this purpoſe, is of a deep black; and they make choice of a place for their operation not far from a ſpot rich enough in *nitre* to keep them conſtantly at work, at leaſt during a whole ſummer, and ſuch as can ſupply them with water and wood at an eaſy expence. The utenſils, uſed in this manufacture, are a large copper boiler, containing about 60 amphors of 6 gallons, or about 54 lb of water each, which is fixed in the ground, with its brim level with the ſurface; 100 wooden tubs, with a hole bored near the bottom, each of which holds a car of earth, or about 4 or 5 amphors; 2 very large caſks of about 100 amphors each; about 32 wide troughs or coolers, holding about an amphor each; and a ſufficient number of amphors for fetching water.

In the manufacture, the firſt operation is to beat the nitrous earth to a coarſe powder with iron ſpades, and to clear it of all hard ſubſtances. If it be very rich in *nitre* (indicated either by its fatneſs or its downy efflorefcence), they mix with it ſome of a poorer ſort, in equal quantity, but very black and old: and, laſtly, they add aſhes, commonly thoſe of the aſh, which moſt abounds, to the amount of about a fifth part of the whole, and mix them well together. If they have a quantity of urine at hand, they throw it in, but never any quick lime: they then put one car of the prepared nitrous earth into one of the tubs, fill up the veſſel with cold water, and ſtir the whole well with a wooden ſtaff; and after it has ſtood twenty-four hours, with occaſional ſtirring, they ſuffer the ley to run out at the hole near the bottom, and put it into two large caſks. In this decoction of the *nitre*, what they call the *mother of nitre* is abſolutely neceſſary. This is the inſpiſſated lixivium remaining after the cryſtallization of *nitre*, which cannot itſelf be made to cryſtallize, and they keep it from one year to another. Of this mother of *nitre*, they pour one or two tubs into the boiler, to which they add the new ley, collected in the great caſks, till the boiler is full, and keep the contents boiling near twenty-four hours. As ſoon as they perceive any marks of cryſtallization on the ſurface, they remove the ley, thus decocted and inſpiſſated, into the thirty-two wooden coolers, and let it remain there twenty-four hours; in which time the cryſtallization being completed, they drain off the mother of *nitre*, and return it into the boiler. The cryſtals are taken out and dried; but as they never prove clean, they are again diſſolved in clean water, filtered through a flannel bag, and boiled up again, in a leſs boiler, to a requiſite thickneſs, and then cryſtallized again, which brings them to be fit for ſale. In this manner, the proceſs is repeated through the ſummer, till the winter's froſt puts a ſtop to it.

A ſingle pound of ſalt petre is ſold, in time of war, on the ſpot where it is made, for four rubles, or ſeventeen ſhillings; but, in time of peace, it is much cheaper.

The earth thus cleared of its *nitre*, is caſt out in heaps about four feet high, and thus left for four years, and the ſame quantity of *nitre* is got out of this earth as before. Upon a third working, after ſeven years more, it will yield ſome *nitre*, but ſcarce enough to defray the charges. This method of making ſaltpetre, ſays Dr. Wolf, came hither from the Eaſt; and there, Dr. Wolf apprehends, it is performed by a ſimilar proceſs.

In many of the eaſtern nations, the ruins of old buildings expoſed to the north-eaſt winds, and ſheltered from rain, have their walls covered with the efflorefcences of a nitrous ſalt, which is uſually thrown with the earth into the *nitre* pit. Earths moiſtened with the excrements of animals, as the earths of pigeon-houſes, and the like, all afford more or leſs *nitre*, and, in France, vaſt quantities are annually made from lime rubbiſh, and the ruins of old buildings.

In Virginia, they prepare the floors of their tobacco-houſes, for attracting *nitre*; the method of making it, in this way, by Mr. Jeremiah Brown, has been publiſhed, in Virginia, by order of the truſtees for the improvement of arts and manufactures, and, in England, by order of the ſociety for the encouragement of arts, manufactures, and commerce. See an account of this method in the Annual Regiſter, for 1763, vol. vi. p. 121.

At Paris, where they have ſeventeen ſaltpetre works, there is a company of perſons employed in making ſaltpetre, in number about twenty. They were incorporated ſo long ago as the reign of Charles IX. and are regulated by ſeveral ſtatutes. The quantity made annually is from 6 to 700,000 lb. They are obliged to deliver it in rough to the royal arſenal, where they receive for it ſeven ſous, or about 3½ *d.* per lb. It is there purified, undergoing three lixiviations, and is then ſold at ten, fifteen, and eighteen ſols per lb.

The method uſed in a conſiderable manufacture is as follows: M. Bouret, who makes every year from 35 to 36,000 lb. employs 6 men night and day, 2 rooms, 20 large caſks, and 3 horſes. The caſks are half filled with old plaſter, which is changed every time of pouring on water, and the lower half with wood aſhes, which are changed but once in five lixiviations. The water poured on ſoaks through both the plaſter and aſhes, and is five times paſſed through freſh plaſter. It is then boiled down in a copper pan, ſo placed, that the flame paſſes quite round its ſides. The fire is made of wood. The lixivium, when properly evaporated, is ſet to cryſtallize, and the cryſtals to drain. The ſcum taken off in the boiling is thrown upon the plaſter, which the longer it lies in heaps (wetted from time to time) becomes the ſtronger; and likewiſe in proportion to the putrid matter thrown upon it. The plaſter uſed in the buildings, at Paris, is made of that gypſeous earth, called plaſter of Paris, and found in the neighbourhood of that city. In general, no lime is mixed with it; and if this be the caſe, the *nitre* is neither ſo good, nor produced in ſo great a quantity. It is known, when the old plaſter is worth being collected and employed, by the ſaltiſh taſte of it. *Nitre* is alſo made in other great towns in France.

The moſt favourable places (ſays the author of the Chemical Dictionary) for the production of *nitre* are the habitations of men and animals, and particularly ſuch as are low and moiſt, as cellars, kitchens, ſtables, houſes of office, and others of that kind, which are apt to be impregnated with vegetable and animal matters, and alſo to have an habitual moiſture, which is favourable to putrefaction; and, laſtly, which are ſheltered from rain, which might otherwiſe diſſolve and carry off the *nitre*, as ſoon as it is formed.

Theſe buildings are true *nitre*-beds. When they are old, their rubbiſh and plaſter are full of *nitre*; but this *nitre* is only a *nitre* with an earthy baſis, which is not ſuſceptible of cryſtallization or detonation, which are the two eſſential qualities in *nitre* for the principal uſes to which it is applicable, and which it cannot poſſeſs but by being joined to a baſis of fixed alkali. Beſides, the *nitre* of rubbiſh is mixed with much common ſalt, which comes alſo from the vegetable and animal matters, and from ſome heterogeneous ſubſtances, which alter its purity. The chief intention, therefore, of the operation upon rubbiſh,

rubbiſh, to obtain a perfect *nitre*, is to furniſh this ſalt with a baſis of fixed alkali, and to diſengage it from the heterogeneous matters which alter its purity. Theſe views are accompliſhed in the following manner.

The rubbiſh containing *nitre* is to be broken to ſmall pieces, and mixed with nearly an equal quantity of wood-aſhes. This mixture is to be put into caſks ranged along each other, placed vertically on one of their ends, and ſupported at the height of two feet above the ground. At the bottom of each caſk is a hole, filled with ſtraw. Water is to be poured into the firſt caſk; and this water, when impregnated with all the ſaline matter in the mixture, flows into a bucket placed under the caſk for its reception. This ſame water is poured ſucceſſively into the other caſks, and thus becomes impregnated with more and more ſaline matter. The makers of ſaltpetre obſerve always to paſs the ſtrongeſt lixiviums through caſks filled with new matter; and before they throw away the matter of a caſk when almoſt exhauſted, they paſs through it the firſt water yet unimpregnated. By theſe operations, which are well contrived, they obtain a lixivium as much impregnated as it can be, and they at length entirely exhauſt the rubbiſh of all the *nitre* it contained.

The lixivium of *nitre*, thus prepared, is carried to great copper cauldrons, in which it is boiled and evaporated, till it is ſufficiently ſtrong for the cryſtallization of the ſalts. As the two cryſtallizable ſalts contained in this lixivium are *nitre* and common ſalt, and as the latter of theſe ſalts is cryſtallizable by evaporation only, and the ſecond by cold only; the common ſalt cryſtallizes firſt during the evaporation, and forms ſmall cubical cryſtals which ſubſide to the bottom of the cauldrons. The ſalt-petre makers call it the *grain*. They take it out with large ladles, and put it in a baſket hung over the cauldrons to drain. This evaporation is continued, and the grain is to be taken away as faſt as it is formed, till the liquor be ſo much evaporated, that, when it is cold, much *nitre* will be cryſtallized in it; and in order to diſcover when it is ſufficiently evaporated for that purpoſe, a ſmall quantity of it is to be taken out from time to time. When they perceive, upon cooling the liquor, that a ſufficient quantity of *nitre* is formed in it, they remove the liquor from the cauldron into large copper baſons, which they carry to a place deſigned for the cryſtallization.

As this liquor contains much *nitre*, and as it is quickly cooled, the greateſt part of the ſalt is coagulated at the bottom of the baſons in unſhapely maſſes, compoſed of many ſmall needle-like cryſtals of *nitre*, and ſometimes of large regular cryſtals upon their ſurfaces. Theſe are called *ſticks of nitre*.

In the baſons remains a large quantity of liquor, the *nitre* contained in which cannot be cryſtallized but by a ſecond evaporation, which is therefore performed in the ſame manner as at firſt, and more *nitre* is obtained. This operation is repeated till no more *nitre* can be formed by cooling the evaporated liquor, which then becomes very red and acrid, and is called the *mother-water of nitre*.

This mother-water is compoſed almoſt entirely of *nitre* and common ſalt with earthy baſes, which certainly proceed from too ſmall a quantity of aſhes having been mixed with the lixivium of the nitrous rubbiſh. This mother-water may therefore be avoided, by mixing a ſufficient quantity of aſhes with the nitrous rubbiſh, to decompoſe all the ſalts with earthy baſes which it contains; and thus, after the ſeveral evaporations and cryſtallizations, nothing would remain but a ſmall quantity of red liquor impregnated with unctuous matter.

When only the uſual quantity of aſhes is employed, the baſis of the earthy ſalts contained in the mother of *nitre* may be precipitated by adding an alkaline lixivium. This precipitate is white, and is called the *magneſia of nitre*; and, at the ſame time, the *nitre* with earthy baſis in the mother-water, being changed into a *nitre* with baſis of fixed alkali, is eaſily obtainable by cryſtallization: but the ſaltpetre-makers do not employ any of theſe methods with their mother-water, which they throw upon the nitrous rubbiſh after it has been exhauſted of its ſalt by lixiviation. Some time afterwards, they lixiviate this rubbiſh in the ſame manner as they did at firſt, that is, with the addition of aſhes, and obtain from it more *nitre*.—We may eaſily perceive that this operation is preciſely upon the ſame principles as one of thoſe we have propoſed.

The *nitre* obtained by theſe cryſtallizations is red, and ſoiled by the liquor in which it was diſſolved, which has alſo that colour. Farther, although common ſalt does not cryſtallize by cold alone, yet a certain quantity of it always cryſtallizes along with the *nitre*; both becauſe the evaporation continues while the liquor cools, and becauſe the *nitre*, during its cryſtallization, always takes with it a portion of common ſalt.

This *nitre*, which the manufacturers call *nitre of the firſt boiling*, is therefore impure, and mixed with common ſalt, and with ſalts with earthy baſes, by which it is rendered unfit for many of the uſes to which *nitre* is applied; as we ſhall afterwards ſee. It is purified by diſſolving it in pure water, and by proceeding to a ſecond cryſtallization by cold; and as in this ſecond cryſtallization, the proportion of *nitre* to common ſalt, and to ſalts with earthy baſes, is infinitely greater than at firſt; ſo that when the liquor is at the point of the cryſtallization of the *nitre*, it is very far from being ſo much evaporated that the common ſalt can cryſtallize at that time; and therefore the *nitre* obtained in this ſecond operation is infinitely purer than that of the former. It is alſo white; and is called by the manufacturers *nitre of the ſecond boiling*. This is the *nitre* employed by diſtillers of aquafortis for the ordinary aquafortis.

But this *nitre* is not yet ſufficiently pure for the preparation of good gun-powder; and it muſt therefore be purified by a third boiling or cryſtallization. This is the pureſt *nitre* that is ſold, or that is kept in ſhops. It is very beautiful and white; but it is not yet ſufficiently pure for certain delicate operations in chemiſtry, and muſt therefore undergo a fourth purification.

By which ever of theſe methods *nitre* is procured, it is ever in all reſpects the ſame ſalt. Its cryſtals are of a hexaedral priſmatic form, terminated by hexaedral pyramids. It diſſolves in a moderate heat, even much leſs than what is neceſſary to make it red, and does not flame, unleſs a coal, or ſome other ſulphureous body fall in. If *nitre* thus melted be left to cool and fix, it coagulates into a ſolid, ſonorous, ſemitranſparent maſs, and is then called mineral cryſtal. It is ſoluble in eight times its weight of very cold water; in leſs than thrice its weight of water temperately warm, and, as it is ſaid, in one third its weight of boiling water. The origin of *nitre*, or of that acid which forms its characteriſtic part, has been the ſubject of controverſy among chemiſts and naturaliſts. Some have imagined, that, as *nitre* is commonly obtained from ſubſtances long expoſed to the air, the nitrous acid exiſted ready formed, like the other two mineral acids, and that it is ſucceſſively depoſited in matters proper for its reception. But this opinion is now generally rejected; becauſe it is not found in fact, that *nitre* is ever obtained by a long expoſure of the moſt proper ſubſtances for the reception and retention of the nitrous acid, as fixed alkali, to the air; and that *nitre* is never found except in ſubſtances capable of being impregnated with vegetable or animal juices.

Mr. Lemery the younger, having obtained perfect *nitre*, by analyſing many vegetable and animal ſubſtances, concludes from thence, that this ſalt exiſts naturally ready formed in the individuals of theſe two kingdoms, which, according to him, are the only ſource of it. To this opinion it is objected, that the peculiar ſubſtances of which vegetables and animals are compoſed, conſiſt of principles extracted from the air and the earth, whence, it may be alleged, that the *nitre* found in them originally proceeds.

Another more probable opinion, concerning the origin of *nitre*, is that of Stahl. This chemiſt apprehends, that the nitrous acid is only the vitriolic acid metamorphoſed by the union it contracts with phlogiſton; and that putrefaction is the means employed by nature to combine this acid with the inflammable matter of putrefying ſubſtances, in the proportion and manner proper for giving it the ſpecific character of nitrous acid. See Dictionary of Chemiſtry, art. NITRE.

This ſalt gives the greateſt of all proofs of the effects of ſynthetical, or recompoſing chemiſtry. It is firſt ſeparated, or analyſed, in the following manner: take two pounds of refined ſaltpetre in fine powder; pour upon it one third of its weight of oil of vitriol, diſtil it in a glaſs retort, in a ſtrong ſand heat, and there will be produced a ſtrong acid ſpirit of *nitre*, which cannot, by any experiment, be found to participate at all of the nature of the oil of vitriol uſed in its preparation. Then take a pound of freſh *nitre*, melt it in a crucible, and throw into it, at times, pieces of charcoal, till it will no longer keep in fuſion with the ſame degree of fire; then increaſe the fire, and melt it, and then pour it into a proper veſſel; leave it to cool of itſelf: this is fixed *nitre*, and is an alkali. Now diſſolve this fixed *nitre* in water, and exactly ſaturate that water with the acid ſpirit of *nitre* before diſtilled; this compound liquor will, by ſtanding, ſhoot into true and perfect cryſtals of *nitre*. And the experiment ſucceeds as well, if a ſolution of pot-aſhes, or any other fixed alkali, be uſed inſtead of that of fixed *nitre*. Shaw's Lectures, p. 170.

Of all the ſalts which afford us thoſe ſtrong liquors commonly known by the name of the mineral diſſolvents, ſaltpetre, or *nitre*, is the only one which yields red va-

pours

pours, or whose ſpirit riſes in form of red vapours, as ſoon as it is ſeparated by means of fire; but the reaſon of this fact has never been accounted for, till Mr. Hellot explained it to the Academy at Paris, in one of his memoirs.

Of the chemiſts who have before treated of it, ſome imagined that the redneſs of the vapours was owing to ſome part of the ſulphureous ſubſtances which the ſalt had imbibed from the urine and dung of animals, where it was formed; others, that this colour was owing to particles of fire carried up with the vapours in their aſcent. But theſe are weak conjectures; ſince, if the firſt were the caſe, the mixtures of ſal ammoniac with common ſalt of vitriol, ought to yield red vapours in diſtillation, which never is the caſe; and if the latter be ſuppoſed, it is not eaſy to ſay, why oil of vitriol does not ariſe in the ſame coloured vapours; ſince it requires a more violent, and longer continued fire to raiſe it.

Vitriol is added to *nitre* in the diſtillations which yield theſe red vapours, and it is the firſt point to be determined in inveſtigating this phenomenon, whether the vapours owe their colour truly to the *nitre*, or whether they borrow it from the additional vitriol. Baldwin, Stahl, and many others, are of opinion, indeed, that the red vapours are owing to the vitriol, and eſſential to it, and call them the *anima nitri*; and they prove the aſſertion by the known obſervation that *nitre*, melted with a tender white glaſs, turns it to purple, or ſome ſhade of red; whereas neither alum, common ſalt, nor the fixed alkalis give this colour: and it is probably ſome portion of an ammoniacal urinous ſalt, mixed in the *nitre*, which gives the colour, ſince ſal ammoniac will give the ſame colour when fuſed with glaſs. What is it, however, in the ſal ammeniac which has this effect? not its volatile alkali, for that is diſſipated in the mixture by the firſt efforts of the fire; neither can it be the acid ſpirit of ſea ſalt, ſince experiment proves that it can have no ſuch effect, when employed alone.

A little crocus martis, or any calx of iron, does the ſame thing to glaſs, and ſometimes even the ſmoak of the furnace will do it, when woods of too reſinous a kind are employed as fuel; many a large quantity of what was meant for pure cryſtalline glaſs having been tinged red, or purple, in this manner, and wholly ſpoiled; and all that we can judge on the whole, as to *nitre*, or ſal ammoniac tinging them, is, that it is a fatty, or unctuous matter in thoſe ſalts which produces the colour: and, in all probability, *nitre* contains, beſides a quantity of urinous or ammoniacal ſalt, a ſmall quantity of a ferrugineous matter, in extremely minute and imperceptible particles.

Mr. Lemery has proved that all the ſaltpetre made in Europe has been originally an ammoniacal ſalt; and, indeed, if *nitre* be rubbed for a conſiderable time in a glaſs mortar made warm, with a quantity of a fixed alkali ſalt, it will afford an urinous ſmell. It is not eaſy to prove that all ſal ammoniac contains ferrugineous matter; but when we conſider that iron is always found in the aſhes of vegetables, and that it, therefore, evidently aſcends in extremely minute particles, with the juices of plants; and that ſal ammoniac is prepared from a ſoot made of the excrements of thoſe animals which feed on plants, we ſhall find it no impoſſibility that iron ſhould be there; and we well know that iron, in any ſtate, cannot but give that colour to glaſs, which *nitre*, in a ſmaller quantity, and ſal ammoniac, in a larger, are able alſo to give. Memoirs Acad. Scienc. Paris, 1736.

All obſervations and experiments would ſeem to prove that the red colour given to glaſs by *nitre*, can only be owing to ferrugineous, or ammoniacal matter contained in it; and it is no very raſh conjecture, to ſuppoſe that the ammoniacal matter contained in the ſaltpetre, rarifying, and extremely dividing the ferrugineous matter, during the time of the diſtillation, may diſtribute it, in its diſjunct molecules, to all that matter, or thoſe particles, which form thoſe vapours, and tinge them red by its diſtribution of them.

It is to be obſerved, however, that the vapour of ſpirit of *nitre*, or of aqua fortis, are not always red, but only are ſo when the fire is great enough to raiſe with the vapours the matter which colours them; for if ſpirit of *nitre* be made with the addition of alum calcined, with dry ſaltpetre, and with filings of zinc, mixed together, there will be obtained, with a ſmall degree of fire, a ſpirit of *nitre*, which does not come over in red fumes.

If the fire be raiſed to a greater degree of violence, there will afterwards be obtained a ſecond ſpirit of *nitre*, which will come over in red fumes; but the firſt of theſe will ſhew the great experiment of taking fire on mixture with oil of turpentine, or the European oils of vegetables, better and more readily than the other.

It is therefore no eſſential character of ſpirit of *nitre* to riſe in red vapours, ſince the firſt riſes without; and this is truly the pure ſpirit of *nitre*; while the ſecond, which riſes in red fumes, is impure, being coloured by ferrugineous, or other foreign matter, raiſed in vapour with the reſt, by the great violence of the heat.

It is obſervable, that if vitriol, calcined to a redneſs, be uſed with the *nitre*, for drawing the ſpirit, the vapours riſe of a perfect blood-red. In the common way of diſtilling what is called ſimply ſpirit of *nitre*, the cuſtom is to put into the retort, with the ſaltpetre, a very large quantity of a vitriolic earth; and in the making that ſpirit called aqua fortis, green vitriol or Engliſh copperas is mixed with the *nitre*. This is abundantly known to contain a great deal of iron. Here, therefore, is in each caſe a quantity of ferrugineous matter added; and we well know that this can give a red colour to the vapours, with which it is compelled by violence of fire to riſe.—Repeated trials of ſpirit of *nitre*, with mercurial preparations alſo, prove, beyond contradiction, that there is ferrugineous matter in that ſpirit. Many of the common mercurial precipitates, when made with aqua fortis, or with plain ſpirit of *nitre*, may have evidently iron ſeparated from them; and the chemiſts know well that this is not to be ſuppoſed to have been lodged in the mercury, ſince it is very difficult to conceive how that metal ſhould become amalgamated with it; but there can be no difficulty of ſuppoſing it ſeparated from the menſtruum, ſince it is evident, that there is iron contained in the matters uſed in the diſtillation of it, and even in the ſalt itſelf, from which it is originally drawn.

It would be very natural to ſuppoſe, that the ferrugineous matter was raiſed only from the additions of pure vitriol, or a vitriolic earth; but it is evident, from the experiment of *nitre* alone turning glaſs red, that there is certainly alſo ferrugineous matter in that ſalt itſelf; nor is it at all difficult to conceive how iron comes to enter the body of that ſalt; ſince, if we conſider it as made in Europe, from the rubbiſh of old buildings, and the cleanſings of ſtables, &c. it is eaſy to conceive that pieces of iron of ſeveral kinds may have been ruſted away, and conſumed there, and ſo mixed among the matter from which the ſalt was afterwards made. The addition of wood aſhes, always uſed in the making of it, may have alſo lodged ferrugineous matter among it, ſince it has been often proved that the aſhes of all vegetables contain true iron. Memoirs Acad. Scienc. Par. 1736.

It may ſeem a difficult thing to conceive, however, in what manner ſo ſmall a quantity of iron, as there can be ſuppoſed to be in *nitre*, is able to colour ſo large a body of vapours as are ſeen to riſe in the diſtillation. But if we conſider the extreme diviſibility of the particles of metals into colouring matter, and the vaſt quantity of water that a ſingle grain of copper is capable of tinging blue, when diſſolved in an alkali, we ſhall be the leſs ſurpriſed at it; eſpecially if it be conſidered alſo that it has been proved already, that there is true ſal ammoniac in all *nitre*; and it is well known, that this ſalt is capable of rareſying, and extremely dividing the particles of that or any other metal; and if as much ſal ammoniac as can be diſſolved in aqua fortis be added to that ſpirit, it is well known alſo that it will make it ſend up vapours much redder than before, which can only be owing to the ſal ammoniac raiſing a larger quantity than ordinary of the ferrugineous matter contained in the aqua fortis than would naturally have been raiſed from it.

The moſt ready way of reducing *nitre* to powder is to diſſolve a quantity of it in as little water as may be, and evaporate the water over a gentle fire, continually ſtirring it till dry, by which means the *nitre* will be found in form of a very dry white powder. This is the method uſed by the gunpowder-makers.

The curious in the hiſtory of *nitre*, and its preparation from vegetables, &c. and the purifying it for gunpowder, and other uſes, may conſult the works of Glauber, Stahl, and Clark, on the ſubject of this ſalt, and compare them with the diſcourſe of the younger Lemery, on the origin of *nitre*.

The uſe of *nitre* is very extenſive in medicine, in the arts, and in chemiſtry.

Dr. Shaw, on this occaſion, obſerves, that if the medicinal virtues of *nitre* were to be enumerated, as they ſtand confirmed by ſufficient experience, perhaps they would prove more numerous than thoſe of any one known medicine beſides. It is ſerviceable in the ſtone and ſtoppages of urine, in deſirums, malignant fevers, diarrhœas, the ſmall pox of the confluent kind, &c. ſo as to prove almoſt a general remedy. And all theſe excellent qualities are in this ſalt joined to that deſireable property of being innocent, or ſcarce any way prejudicial to the body. The uſual doſe of *nitre*, among us, is from two or three grains to a ſcruple; though in many caſes it may be given with ſafety, and to better advantage, in larger quantities. From ſome experiments on the effects of

nitre taken internally, related in Mr. Alexander's Experimental Essay, it appears, that *nitre* has a power of almost instantly retarding the velocity of the circulation of the blood, and of surprisingly diminishing the number of arterial pulsations; and that its effects are much more powerful when newly dissolved in water than when it has remained dissolved during some hours. As this difference must have proceeded from the cold which is produced by *nitre* during its solution, probably a much greater effect would be produced by procuring that solution in the stomach. For the various medicinal preparations of *nitre*, see the following articles and references.

In chemistry, besides the nitrous acid obtained from *nitre*, which is one of its most powerful agents, *nitre* itself is also used in many chemical operations. And in the arts, its properties of detonating with bodies containing phlogiston, of accelerating their calcinations, and especially the calcination of the imperfect metals, render it useful for the purification of gold and silver, when they are alloyed with other metals. As *nitre* is quickly and easily alkalised, it enters into the composition of reducing fluxes, or of simple fluxes, to assist fusion and vitrification. It may also be employed by its detonation to discover the presence of the inflammable principle in substances. But the most considerable use of *nitre* is for the preparation of GUN-*powder*. See also AQUA *fortis*, AQUA *regia*, ÆTHER, CRYSTAL *mineral*, SAL-*polychrest*, &c.

NITRE, *alkalised*, is the fixed alkali remaining after the nitrous acid has been destroyed by its detonation with any inflammable matter. This alkali is generally called FIXED NITRE.

NITRE, *ammoniacal*, is a neutral salt resulting from the combination of the nitrous acid, to the point of saturation, with volatile alkali. The acid, in the most concentrated state in which it is commonly met with, saturates about five-sixths its weight of vegetable fixed alkali.

NITRE, *antimoniated*. See *Diaphoretic Nitre of* ANTIMONY.

NITRE, *calcareous*, is a neutral salt, compounded of the nitrous acid combined to saturation with a calcareous earth; and generally called *nitre with an earthy base*. This salt is very deliquescent, but incapable of a true crystallization. It has a poignant, acrid, and bitter taste. See NITRUM *Calcarium*.

NITRE, *cleyssus of*. See CLEYSSUS.

NITRE, *cubic, or quadrangular*, is a neutral salt, formed by the nitrous acid when saturated with mineral alkali. This crystallizes not into a prismatic but a cubical figure, and sometimes into parallelopipedons, with rhomboidal faces. It is inferior to ordinary *nitre*, and never used.

NITRE, *decoction of*, is prepared by boiling half an ounce of *nitre*, and two ounces of fine sugar, with a scruple of cochineal as a colouring material, in 2½ pints of water, till half a pint is wasted, and after standing to settle, the clear purplish red liquor is poured off for use.

NITRE, *detonation of*. See DETONATION; under which article, the reader will find Mr. Macquer's hypothesis, that has been thought to be the most satisfactory; with a hint of another solution of the phenomenon by Dr. Priestley. In a work since published, he has applied the doctrine of dephlogisticated air more particularly to the explication of this process. It appears, he says, that the nitrous acid cannot be heated to a certain degree, in contact with any earthy matter, without producing dephlogisticated air; by the help of which all combustible substances burn with the greatest violence, much more than they can be made to burn with in common air. Here then he supposes that the moment the acid of *nitre*, contained in the *nitre*, and the earth of the coal, for example, thrown into it become red hot, in contact with each other, dephlogisticated air is produced; and in this air the remainder of the charcoal, being likewise red hot, burns with the violence that is observable in the experiment; while, at the same time, other portions of the nitrous acid are forming, with other parts of the same decomposed charcoal, the union that constitutes more dephlogisticated air; and thus the detonation continues, till all the charcoal, or all the *nitre*, is consumed; the acid not being *fixed*, as some chemists express it, but entering into the composition either of the dephlogisticated air, or of some other kind of air, that may be generated in the process.

NITRE, *diaphoretic, of antimony*. See ANTIMONY.

NITRE, *fixed by arsenic*, is the alkali of *nitre*, the acid of which has been expelled in an open fire by means of arsenic, of which some portion is retained by the alkali. This may be employed as a flux, as it greatly assists vitrification.

NITRE, *fixed by coals*. See FIXED *Nitre*.

NITRE, *fixed by metals*, is the alkali of *nitre* separated from its acid, and mixed with the earth of the calcined metals.

NITRE, *fixed by tartar*, is the alkali of *nitre* and that of tartar mixed together by means of detonation. This is called the *white flux*.

NITRE, *Glauber's spirit of*. See SPIRIT.

NITRES, *metallic*, a general denomination that comprehends all neutral salts composed of the nitrous acid united with a metallic substance; the several kinds of which may be thus distinguished, viz. *nitre* of SILVER, called *lunar* CRYSTALS, *nitre* of LEAD, *nitre* of MERCURY, &c. The acid acts in general powerfully upon all metallic substances, but with remarkable differences, depending on the peculiar natures of the metals. It dissolves zinc, iron, copper, bismuth, lead, mercury, and silver, the most readily of all the acids; tin it dissolves imperfectly; regulus of antimony it only corrodes: gold and platina cannot be dissolved by nitrous acid alone, without the concurrence of marine acid.

NITRE, *nitred*. See NITRUM *nitratum*.

NITRE, *purified*. See NITRUM *purificatum*.

NITRE, *spirit of*. See SPIRIT.

NITRE, *troches of*, are made by grinding one part of the purified salt with three parts of fine sugar, and making up the mixture with mucilage of gum tragacanth.

NITRE, *vegetating*. See NITRUM *Vegetans*.

NITRE, *vitriolated*. See NITRUM *Vitriolatum*.

NITRO-AERIAL *spirit*, a term invented by Mayow, and since used by many others, to express a very active principle in the air, causing great changes in the bodies absorbing it, and exposed to it.

The acid spirit of nitre is produced, according to Mr. Boyle, partly by the air, and partly by a terrestrial matter making up the rest of the body of that salt. And he further supposes, that igneous particles of the air reside in nitre, and constitute its most active part, and that by these the flame of kindled nitre is produced.

Hence it is inferred, that the aerial particles of nitre are truly no other than the igneo-aerial matter of it, and that this aerial matter is evidently lodged in the acid spirit of it, not in the fixed salt. This acid spirit is, according to Mayow, composed of a terrene matter, which is flexile and humid, and of ethereal particles, which are rigid and dry, active and igneous, and proceeding from the air. These igneous particles are common to nitre and to air, and are therefore called *nitro-aerial*; and the spirit of nitre derives, according to this system, from these particles its active and corrosive quality, which makes it a sort of potential fire; and on this the form of nitre chiefly, if not only, depends.

Now as this *nitro-aerial* or igneous spirit resides in the acid spirit of nitre, it is thence inferred, that the *nitro-aerial* spirit is of a nitro-saline nature, obtaining rather the nature of an acid than a fixed salt; considering also, that the effects of fire in general answer to those of a very subtile and corrosive salt. Fire in general, on these principles, is easily proved to depend principally upon the said *nitro-aerial* principle put into motion.

This *nitro-aerial* spirit makes the most active, and, indeed, the principal part of the salt which we call *nitre*. Its terrestrial and acid parts make up the rest of the mass; and these are rather of use to form the whole into a body, and give it form and consistence, than to add to any of its fat.

NITROUS *acid*. See ACID and NITRE, *spirit*.

NITRUM, is used by the poet Martial to express that sort of foulness in crystal, which Pliny, and other of the ancient Roman authors, distinguish by the name of SAL.

NITRUM *calcarium*, in *Natural History*, a name given by Dr. Lister to a peculiar species of neutral salt, which he first publicly described in his book on the medicinal waters of England. He very improperly calls it *nitre*; because it has none of the properties or qualities of *nitre*, but only a sort of general resemblance in its external form. He observes that this salt, though very little known, was abundantly the most copious of all the sorts afforded by the mineral waters in general; and says its crystals were long and slender, and consisted of four sides, and were terminated by a point composed of two triangular planes. He adds, that this salt doubtless had its origin from a mixture of the acid of sulphur, and a calcareous earth of an alkaline nature.

This salt is found in almost all the mineral waters of Germany, and is very justly observed by Hoffman to be of the nature of Glauber's salt: that it is not *nitre* is evident from this, that it is not inflammable, nor will yield aqua fortis by distillation. It seems, indeed, true Glauber's salt, composed of the acid of vitriol, or sulphur, for this is in both the same, and of that alkaline earth which is the basis of sea salt: this is its origin, in the vessels of the chemist, as well as in the bowels of the earth, and probably the figure of the crystals of that observed by Dr. Lister, was the same in the point, as well as in the body, both being quadrilateral columns terminated by pyramids composed of a number of triangular planes. Hoffman Opera, tom. v. p. 139.

The medicinal waters in the neighbourhood of Paris contain it also in a very considerable quantity, though less than this. It is the opinion of Hoffman, that when any

water before impregnated with a vitriolic acid, in its current under ground, paſſes over this calcareous earth, it as readily joins a part of it with it, as the vitriolic acid does with the ſea ſalt, or its baſis, in making the common Glauber's ſalt, and thence produces a bitter purging ſalt, of the ſame nature with that; and, indeed, if the acid of ſulphur be mixed with any alkaline ſubſtance, a bitter neutral ſalt is produced, ſomewhat analogous to this, and to the Glauber's ſalt.

NITRUM *nitratum*, in *Chemiſtry*, the name of a preparation of *nitre*, made by adding a ſufficient quantity of ſpirit of *nitre* to a lixivium of pure *nitre*, and afterwards evaporating it to a pellicle, and ſetting it by to ſhoot. The cryſtals formed by this liquor are perfectly nitrous in their figure, but they will be of an acid taſte.

We ſee, by this, that it is poſſible to alter a ſalt, and to reduce it into the appearance of a different body, by means of ſubſtances before ſeparated from itſelf; and, in this caſe, the alteration is made, in almoſt any degree, at pleaſure; the ſalt produced being more or leſs acid, as more or leſs of the acid ſpirit is uſed: but it is to be obſerved, that the more acid there is uſed, the more difficultly the ſalt dries, and the more difficultly it is kept dry, it being always ſubject to run in the air. This preparation of *nitre* is a good medicine in burning fevers.

NITRUM *purificatum*, *purified nitre*, is thus prepared: take *nitre*, or common ſaltpetre, one pound; pure water three quarts and a pint; ſet them on the fire together, and diſſolve the ſalt perfectly by boiling: then ſtrain the hot lixivium through a double flannel, and ſet it over the fire again in an earthen veſſel. Evaporate it gently, till on taking out a little of the liquor in a ſpoon as it cools, there are ſeen threads as it were ſhooting in it; in this ſtate the ſalt is ready to concrete. Set it in a cool place, putting clean ſticks across the veſſel, and the ſalt will form itſelf into extremely pure and beautiful cryſtals on the ſide of the veſſel, but principally on the ſticks. Theſe dried in a colander are fit for uſe. See NITRE, *ſupra*.

This is the beſt of all the preparations of *nitre*, for medicinal uſe, in its native form. It diſſolves immediately on entering the body, where it wonderfully cools, and thins the blood, giving it a fine florid colour. In all inflammatory diſeaſes attended with condenſations of the blood, this ſalt proves excellently cooling and attenuating. It is given from four or five grains to ten, twelve, or fifteen at a doſe. Some give more at a time, but it is more adviſeable to have the doſes ſmaller, and oftner repeated. It is alſo good in the ſmall-pox, and ſuppreſſions of urine. It is alſo ſaid to be given by many in hæmorrhages with ſucceſs. If there be any caſe in which caution is required, it is in a conſumption where the lungs are ulcerated. Of this purified *nitre*, a ſafe and powerful alterant is readily and eaſily prepared in the following manner: take an ounce of the *nitre*, and two ſcruples of cochineal, in fine powder; boil theſe in five or ſix ounces of water; filter the liquor, and afterwards evaporate it to a dryneſs, ſtirring it continually, as it thickens, and a fine purple powder will be then produced, fit to be given in the form of bolus, pills, powder, &c.

NITRUM *vegetans*, a name given by the chemiſts to a preparation of *nitre*, which very readily ſhoots out into beautiful cryſtallizations. If, in making Glauber's ſpirit of *nitre*, there are uſed four parts of *nitre*, and one of oil of vitriol, and the ſpirit be entirely driven off, the white ſalt remaining dry in the retort, on being expoſed to the open air, will ſoon be covered with a thick and long down, as if it grew; but if this ſalt be diſſolved in water, and then ſtrained, and evaporated to a dryneſs, in a cylindrical glaſs, and kept expoſed to the open air, its upper ſurface will often appear covered with beautiful branching little plants, all which will diſſolve away upon the application of heat, and leave the ſurface even; but upon expoſing the veſſel again to the open air, in a quiet place, they will grow again as before, thus ſeveral times exhibiting the reſuſcitation of plants, as it were, from their own aſhes.

Some chemiſts have formed ſeveral fables upon ſome ſuch baſis as this; and very probably, the whole ſecret of their operations was no more than a concealed fraud of this kind, this having nothing to do with vegetation.

NITRUM *vitriolatum*, a preparation of *nitre* made as follows; diſſolve the maſs left in the retort after diſtillation of a ſpirit of *nitre*, in about eight times its weight of water; filtrate the ſolution, and, when perfectly clear, evaporate the liquor to ſuch a ſtandard, that the ſalt will no longer be ſuſtained in it; then ſet it in a cool place, and collect the ſalt as it ſhoots, laying it in an earthen colander to dry. This is of much the ſame virtues with TARTAR *vitriolated*, and is frequently ſold under its name.

NITTLES, in *Sea-Language*. See KNITTLE.

NIVALIS *avis*, or *emberiza nivalis* of Linnæus. See SNOW-*bird*.

NIURI, in *Botony*, the name of a genus of plants, called by Linnæus PHYLLANTHUS.

NOAH's *ark ſhell*, in *Natural Hiſtory*, the name of a kind of ſea ſhell, which authors were always puzzled about referring to any genus, till a late French author has referred it to a new genus he has made under the title *cardiformis*, taking in the bucardia, and triangular heart-ſhells. The cabinets of the curious afford us three ſpecies of this ſhell; the common kind, a yellow and white kind, with broad irregular lines, and a variegated kind.

We have another ſhell of this genus, which no one ever doubted to belong to it, which yet is of an oblong figure, and ſo much reſembles the *Noah's ark*, as to plainly ſhew they ought both to be reckoned ſpecies of the ſame genus. This is the oblong bucardium, or ox-heart ſhell, commonly called the *baſtard Noah's ark*.

NOACHI *columba*, in *Aſtronomy*. See COLUMBA.

NOBILIARY, a collection, or hiſtorical account, of the noble families of a province, or nation.

Chorier has publiſhed a *nobiliary* of Dauphiné; and Caumarin, another of Provence. The Germans are particularly careful of their *nobiliaries*, to keep up the purity of their families.

NOBILISSIMUS, in *Antiquity*, a title, or quality, given to the princes of the imperial family.

F. Doucine advances, that the title *nobiliſſimus* was firſt given under the emperor Juſtin; others find the title *nobilis Cæſar*, or *N. C.* that is, *Nobiliſſimus Cæſar*, on medals long before that time, even as early as Trajan. Spanheim and Joubert, indeed, ſee this title on medals no higher than the time of Philip the Younger; though it appears earlier in ſome inſcriptions; to that even M. Tillemont is miſtaken, where he ſays, the quality of *nobiliſſimus* is not to be found in hiſtory before the time of Conſtantine the Great, who firſt gave it to his two brothers; after which it was attributed to ſuch of the emperors children as were not Cæſars. See CÆSAR.

Triſtan adds, that the Cæſars bore the title of *nobiliſſimi* in all ages; but that *the nobiliſſimate* firſt became a diſtinct independent dignity in the time of Conſtantine the Great.

NOBILITY, a quality that dignifies, or renders a thing noble; particularly, that raiſes a perſon poſſeſſed thereof above the rank of a peaſant or commoner.

In England, indeed, the term *nobility* is reſtrained to degrees of dignity above knighthood. Every where elſe, *nobility* and gentility, or gentry, are the ſame. See GENTLEMAN.

Some refer the origin of *nobility* in Europe to the Goths; who, after they had ſeized a part of Europe, rewarded their captains with titles of honour, and called them *nobles*, *nobiles*, to diſtinguiſh them from the common people.

Nobility, in England, is only conferred by the king, and that by writ or patent, in virtue whereof it becomes hereditary. In other countries there are other ways of acquiring it.

Thus, in France, v. gr. there are ſeveral offices which convey perſonal *nobility*, and ſuch as deſcends to poſterity. Such are all offices of the crown, thoſe of counſellor of ſtate, &c. others they have which only communicate an acceſſory, or perſonal *nobility*, which dies with the perſon. Thus, a counſellor in parliament enjoys all the rights and exemptions of *nobility*; yet his ſon is never reputed noble: unleſs there have been a ſucceſſion of them, and both father and grandfather have been noble; which they call *pere & aieul nobles*.

They have a third kind of *nobility*, called *nobility of the bell*, *de la cloche*; which is what the mayors and ſheriffs of certain cities, as Lyons, Bourges, Rochelle, Poitiers, &c. acquire in virtue of their magiſtracy.

The *nobility* of England is called the *peerage of England*. Its degrees are only five; viz. that of a duke, a marquis, earl or count, viſcount, and baron. See under DUKE, MARQUIS, &c.

The privileges of the Engliſh *nobility* are very conſiderable: they are all eſteemed as the king's hereditary counſellors, and are priviledged from all arreſts, unleſs for treaſon, felony, breach of peace, condemnation in PARLIAMENT, and contempt of the king. No ſupplicavit can be granted againſt them; no capias, or exigent, ſued againſt them for action of debt, or treſpaſs; and no eſſoign lies againſt them: in criminal caſes, they are only to be tried by a jury of peers, who are not put to their oath; but their verdict upon their honour ſuffices. They alſo anſwer to bills in chancery upon their honour, and not upon their oath; but when they are examined as witneſſes either in civil or criminal caſes, they muſt be ſworn. In their abſence from parliament, they are allowed a proxy to vote for them; and in all places of truſt they are allowed to conſtitute deputies, by reaſon of the neceſſity the law ſuppoſes them under of attending the king's perſon. See PEERS and PARLIAMENT.

Guillim

Guillim obſerves, that if an APPEAL of murder, or felony, be ſued by a commoner againſt a peer, he ſhall be tried by commoners, not peers.

No peer may go out of the kingdom without the king's leave: if any have leave, he is to return upon the king's writ, or to forfeit goods and chattels.

Anton. Matthæus obſerves, that *nobility*, among the Romans, was a quite different thing from what it is among us. The nobles, among the Romans, were either thoſe raiſed to the magiſtrature, or deſcended from magiſtrates: there was no ſuch thing as *nobility* by patent.

Bartoli ſays, that doctors after they have held a profeſſor's chair in an univerſity for twenty years, become *noble*; and are intitled to all the rights of counts.

But this claim is not admitted at court, &c. though Bartoli's ſentiments be backed with thoſe of ſeveral other authors, particularly Chaſſanæus in his Conſuetudin. Burgundiæ; Boyer ſur la Coutume de Berry; Faber C. de Dig. Def. 9. &c. which laſt, however, reſtrains Bartoli's rule to doctors in law, and princes phyſicians.

By an edict of the French king, in 1669, it is declared, that trade ſhall not derogate from *nobility*, provided the perſon do not ſell by retail.

In Bretagne, by ancient cuſtom, a nobleman loſes nothing by trading even in retail: but he reaſſumes all his rights as ſoon as he ceaſes traffic, his *nobility* having ſlept all the time.

In Germany, a woman, not *noble* by birth, doth not become, v. gr. a counteſs, or baroneſs, by marrying a count, or baron: a lady of the higher degree, indeed, becomes a princeſs by marrying a prince; but this doth not hold of a lady of the lower *nobility*.

On the coaſt of Malabar, children are only capable of being *noble* by the mother's ſide; it being allowed them to take as many huſbands as they pleaſe, and to quit them whenever they think good.

NOBLE, NOBILIS, a perſon who has a privilege which raiſes him above a commoner, or peaſant, either by birth, by office, or by patent from his prince.

The word comes from the Latin *nobilis*; formed from the ancient *noſcibilis*, *diſtinguiſhable*, *remarkable*.

In England, the word *noble* is of a narrower import than in other countries; being confined to perſons above the degree of knights; whereas, abroad, it comprehends not only knights, but what we ſimply call *gentlemen*.

The *nobles* of England are alſo called *pares regni*, as being *nobilitatis pares*, though *gradu impares*.

The Venetian *nobleſſe* is famous: it is in this that the ſovereignty of the ſtate reſides. It is divided into three claſſes. The firſt only comprehends twenty-four families.

The ſecond includes the deſcendants of all thoſe who were entered in the golden book, in 1289, and deſtined to govern the ſtate, which then began to be ariſtocratic.

The third conſiſts of ſuch as have bought the dignity of *noble* Venetians.

This laſt claſs is only admitted to the inferior employs; the two former, to all indifferently.

The title of *noble* Venetians is ſometimes alſo given to foreign kings, princes, &c.

NOBLE alſo denotes a money of account, containing ſix ſhillings and eight pence.

The *noble* was anciently a real coin, under the denomination of ROSE-*noble*.

Authors obſerve, that there has not been any piece of gold or ſilver of this name, coined with us ſince 9 Hen. V. They were firſt coined by Edw. III. in 1334. See GOLD *coin*.

The *noble* contained 80*d.* the ſame with the preſent money of account. Its half was called *ob'lus*, containing 40*d.* its fourth part the quadrans, or farthing in thoſe days, 10*d.*

NOCERIANA *terra*, *earth of Nocera*, in the *Materia Medica*, a white earth, being a ſpecies of bole, uſed in medicine in Germany, Italy, and ſome other parts of the world, but not known in the Engliſh ſhops. It is found at *Nocera*, in Umbria, whence its name. It is now dug principally about Macerata, a city in the marquiſate of Ancona, in the pope's territories, and is in great eſteem in malignant fevers, and againſt the bites of venomous animals.

It is a denſe earth, of a greyiſh white, very hard, and of an inſipid taſte, and does not effervеſce with acid menſtruums.

NOCTAMBULATIO, compounded of *nox*, *night*, and *ambulo*, *I walk*, *walking in the ſleep*. This is a very remarkable diſtemperature of the imagination, and, in different perſons, differs greatly in degree. Thoſe who are but moderately affected with it, only repeat their actions of the day, and getting out of the bed, go quietly to the places they frequent at other times; but thoſe who are afflicted with it in the moſt violent degree, go up to dangerous places, and do things that would terrify them to think of, when awake: theſe are by ſome called lunatic *night-walkers*, becauſe, as ſome have imagined, fits are obſerved to return with moſt frequency, and violence, at the changes of the moon.

Cauſes of it. The only material cauſe that can be aſſigned in this caſe is a plethora, or over-fulneſs of blood; but this is influenced by an immaterial one, that is, by the fancy, which is buſily employed in dreams about particular objects.

Method of cure. The primæ viæ are firſt to be cleared of all their foulneſſes by a ſtrong purge; after this it is proper to bleed in the foot, taking away eight or ten ounces; then powders compoſed of nitre, cinnabar, and crab's eyes, ſhould be taken three or four times a day, and particular regard, it is ſaid, ſhould be had to the changes of the moon. It will be proper to ſet a veſſel of water by the bed-ſide, in ſuch a manner that the perſon will naturally ſtep into it on getting out, and be awaked by that means; and if theſe things fail, a perſon ſhould be ſet up to watch him, and beat him every time it happens. Junker's Conſp. Med p. 698.

NOCTANTER, in *Law*, is the name of a writ iſſuing out of the Chancery, and returnable in the King's Bench; given by the ſtatute Weſtm. 2. 13 Edw. I. cap. 46. by virtue of which ſtatute, where any one having right to approve waſte ground, &c. makes and erects a ditch or a hedge, and it is thrown down in the night time, and it cannot be known by a verdict of aſſize or a jury, by whom; if the neighbouring vills will not indict ſuch as are guilty, they ſhall be diſtrained to make again the hedge or ditch at their own coſts, and to anſwer damages. The word *noctanter* is ſo neceſſary in an indictment of BURGLARY, that it hath been adjudged inſufficient without it.

NOCTIBO, in *Ornithology*, the name given by the Portugueſe to a ſmall Braſilian bird, a ſpecies of the *goat-ſucker*, or *churn-owl*, more known among naturaliſts by its Braſilian name IBIJAU.

NOCTILUCA, among *Naturaliſts*, a ſpecies of phoſphorus, ſo called, becauſe it ſhines in the night, without any light being thrown on it: ſuch is the phoſphorus made of urine.

By which it ſtands diſtinguiſhed from ſome other ſpecies of phoſphorus, which before they ſhine, muſt be expoſed to the ſun-beams; ſuch is the BONONIAN-*ſtone*, &c.

Mr. Boyle, in a particular treatiſe on the ſubject, gives an account of three *noctilucæ*. The firſt, invented by Kraſft, he calls the *conſiſtent*, or *gummous noctilucæ*, as being of a texture not unlike that of a cherry-gum. This, on account of its uninterrupted action, was, by the Germans, called the *conſtant noctilucæ*; among us it is now known under the denomination of the *ſolid phoſphorus*. The ſecond is liquid, invented by the ſaid Kraft: this is only a diſſolution of the former in a convenient liquor. The third kind was prepared by Mr. Boyle himſelf; and was of a different nature from both the other; for it would not ſhine of itſelf, like either of them, but required the contact of the air (though not any external rays or heat) to make it produce light, which would be very durable, in a well ſtopped veſſel. Add, that it was not the body that ſhone, but an exhalation, or effluvium, mixed with the air; on which account the inventor gives it the denomination of the *aerial noctilucæ*.

The ſame Mr. Boyle, afterwards, prepared another ſort; which, from the little peſſucid fragments or cruſtals therein, he denominated the *icy noctilucæ*. See PHOSPHORUS.

NOCTUA *aurita*, in *Ornithology*, a name by which ſome have called the ſmaller ſpecies of the *horned-owl*, more uſually diſtinguiſhed by the name OTUS.

NOCTUA *canora*, in *Ornithology*, a name given by Nieremberg to a bird of the Spaniſh Weſt Indies, called by the natives CHICUATLI, and ſometimes kept by the Spaniards in cages.

NOCTUA *minor*, in *Ornithology*, the name given by Mr. Ray to the *kraunith*, or, as others call it, the SCHAPELIT, a very beautiful little bird of the owl kind, and not exceeding the ſize of the common thruſh.

NOCTUINI *oculi*, a name given by ſome to grey eyes, from their reſembling thoſe of the *noctua*, or *owl*.

NOCTUOLENT, among *Botaniſts*, a name given to ſuch plants as ſmell ſtrongeſt in the night-time. See DOG-*roſe*.

NOCTURNAL, ſomething that relates to night, *nox*; in contradiſtinction to diurnal. In this ſenſe we ſay, *nocturnal* aſſemblies; *nocturnal* walks; *nocturnal* pollutions, &c.

NOCTURNAL *pains* are a frequent concomitant of venereal diſorders, which can only be palliated with narcotics: nothing but a mercurial courſe, or a long-continued uſe of diet-drinks, can entirely remove them.

NOCTURNAL *arch*, in *Aſtronomy*, the arch of a circle deſcribed by the ſun, or a ſtar, in the night.

*Semi-*NOCTURNAL *arch of the ſun* is that portion of a circle he paſſes over between the lower part of our meridian, and the point of the horizon wherein he ſets; or between the point of the horizon wherein he ſets, and the lower part of our meridian.

NOCTURNAL, or NOCTURLABIUM, is more particularly uſed for an inſtrument, chiefly uſed at ſea, to take the altitude or depreſſion of ſome of the ſtars about the pole, in order to find the latitude, and the hour of the night.

There are *nocturnals* of various contrivances, ſome of them projections of the ſphere; ſuch as the hemiſpheres, or planiſpheres, on the plane of the equinoctial: thoſe ordinarily uſed by the ſeamen are two; the one adapted to the polar ſtar, and the firſt of the guards of the Little Bear; the other to the pole-ſtar, and the pointers of the Great Bear.

NOCTURNAL, *conſtruction of the*. The inſtrument conſiſts of two circular plates (*Tab. Navigation. fig.* 15.) applied on each other. The greater, which has a handle to hold the inſtrument, is about 2½ inches diameter, and is divided into twelve parts, agreeing to the twelve months; and each month ſubdivided into every fifth day: and ſo, as that the middle of the handle correſponds to that day of the year, wherein the ſtar here regarded has the ſame right aſcenſion with the ſun.

If the inſtrument be fitted for two ſtars, the handle is made moveable. The upper left circle is divided into twenty-four equal parts, for the twenty-four hours of the day, and each hour ſubdivided into quarters, as in the figure. Theſe twenty-four hours are noted by twenty-four teeth; to be told in the night. Thoſe at the hours twelve are diſtinguiſhed by their length. In the centre of the two circular plates, is adjuſted a long index, A, moveable upon the upper plate. And the three pieces, viz. the two circles and index, are joined by a rivet which is pierced through the centre, with a hole two inches in diameter for the ſtar to be obſerved through.

NOCTURNAL, *uſe of the*. Turn the upper plate till the longeſt tooth, marked 12, be againſt the day of the month on the under plate; then, bringing the inſtrument near the eye, ſuſpend it by the handle, with the plane nearly parallel to the equinoctial; and viewing the pole-ſtar through the hole of the centre, turn the index about, till, by the edge coming from the centre, you ſee the bright ſtar or guard of the Little Bear (if the inſtrument be fitted to that ſtar): then that tooth of the upper circle, under the edge of the index, is at the hour of the night, on the edge of the hour-circle: which may be known without a light, by accounting the teeth from the longeſt, which is for the hour 12.

NOCTURNAL *pollution*. See POLLUTION.

NOCUMENTI *aſſiſa*. See ASSISA.

NODATED *hyperbola*, a kind of hyperbola, which, in turning round, decuſſates or croſſes itſelf.

NODE, NODUS, in *Surgery*, denotes a tumor ariſing on the bones; and uſually proceeding from ſome venereal cauſe.

Node amounts to the ſame with what is otherwiſe called *exoſtoſis*.

It ſeems generated of a thick, cold, viſcid humour, which is often found very difficult to reſolve. They frequently apply to it a leaden plate, covered with mercury.

The cure is frequently alſo attempted by *emplaſt. de vanis cum mercurio*; which failing, ſome mercurial unguent is now and then rubbed on them; and afterwards mercurial plaſters made of cinnabar, &c. are applied.

Some give the denomination *nodes* to all tumors formed by a coagulation of viſcous matter in the external parts of the body.

NODE is more particularly applied to the tumors or protuberances ariſing on the joints of old gouty people; called alſo *tophi*.

They are ſuppoſed to be formed of a thick, crude, heavy, viſcid, indigeſted matter, mixed with a hot, ſharp, bilious juice, the groſſer and more terreſtrial part whereof, being detained, grows into a ſtony ſort of concretion.

NODES, in *Aſtronomy*, the two points wherein the orbit of a planet interſects the ecliptic.

Such are the two points C and D (*Tab. Aſtron. fig.* 33.) whereof the *node* C, where the planet aſcends northwards above the plane of the ecliptic, is called the *aſcending node*, the *northward node*, ☊, and the *head of the dragon*; and is thus marked, ☊.

The other *node* D, where the planet deſcends to the ſouth, is called the *deſcending node*, the *ſouthward node*, or the *dragon's tail*; thus marked, ☋. See DRAGON'S *head* and *tail*.

The right line DC, wherein the two circles interſect, is called *the line of the nodes*.

It appears from obſervation, that the line of the *nodes* of all the planets conſtantly changes its place, and ſhifts its ſituation *in antecedentia*; i. e. from eaſt to weſt, contrary to the order of the ſigns.

Thus, by a retrograde motion, the line of the moon's *nodes* finiſhes its circuit in eighteen years two hundred and twenty-five days; in which time, after having receded from any point of the ecliptic, it returns to the ſame.

Sir Iſaac Newton has not only ſhewn, that this motion ariſes from the action of the ſun, but has calculated, with great ſkill, all the elements and varieties in this motion, from its cauſe.

In order to underſtand the action of the ſun in this caſe, we muſt conceive the plane of the moon's motion to paſs always through the centre of the earth and the centre of the moon, and to be a plane in which the right line forming their centres, and the right line that is the direction of the moon's motion, or the tangent of her orbit, are always found. It is certain, that if the earth and moon were always acted on equally by the ſun, they would deſcend equally towards the ſun; the plane determined always by theſe two lines, would deſcend with them, keeping always parallel to itſelf, ſo that the moon would appear to us to revolve in the ſame plane conſtantly, with reſpect to the earth. But the inequalities in the action of the ſun (ſee MOON) will bring the moon out of this plane to that ſide of the plane on which the ſun is, in the half of her orbit that is neareſt the ſun, and towards the other ſide, in the half of her orbit that is fartheſt from the ſun. Whence we ſhall have this general rule for judging of the effect of the ſun on the *nodes*: that while the moon is in the half of her orbit that is neareſt the ſun, the *node* towards which ſhe is moving, is made to move towards the conjunction with the ſun; and while the moon is in the half of her orbit which is fartheſt from the ſun, the *node* towards which ſhe is moving is made to move towards the oppoſition; but when the *nodes* are in conjunction with the ſun, its action has no effect upon them. In the firſt caſe, the moon is brought into a direction which is on the ſame ſide as the ſun is, of that direction which ſhe would follow of herſelf; and the interſection of a plane paſſing through this direction and through the centre of the earth, will cut the ecliptic, on that ſide towards which the moon moves, in a point nearer the conjunction than if there was no action of the ſun to diſturb her motion. In the other caſe, the action of the ſun has a contrary direction, and for the ſame reaſon makes the enſuing *node* move towards the oppoſition. When the line of the *nodes* produced paſſes through the ſun, then the ſun, being in the plane of the moon's motion, has no effect to bring her to either ſide; and therefore, in that caſe, the *nodes* have no motion at all. By applying this reaſoning, it appears, that in every revolution of the moon, the retrograde motion of the *nodes* exceeds the direct motion, excepting only when the line of the *nodes* paſſes through the ſun, when there is no motion of the *nodes* at all. Sir Iſaac Newton finds, from the theory of gravity, that the *nodes* ought to move backward about 19° 18′ 1″ in the ſpace of a year, and the aſtronomical tables make this motion 19° 21′ 21″, whoſe difference is not $\frac{1}{1000}$ of the whole motion of the *nodes* in a year. By a more correct computation of this motion from its cauſe, the theory and obſervation agree within a few ſeconds. The inclination of the moon's orbit to the ecliptic is alſo ſubject to many variations. When the *nodes* are in the quarters, while the moon moves from one quarter to the conjunction, the action of the ſun diminiſhes the inclination of the plane of her orbit; the inclination of this plane is leaſt of all when the moon is in the conjunction; it increaſes again as ſhe moves from the conjunction to the next quarter, and is there reſtored nearly to its firſt quantity. When the line of the *nodes* paſſes through the ſun, the inclination of the moon's orbit is not affected by the action of the ſun; becauſe, in that caſe, the plane of her orbit produced, paſſes through the ſun, and, therefore, the action of the ſun can have no effect to bring the moon out of this plane to either ſide. In this laſt caſe the inclination of the moon's orbit is greateſt; it decreaſes as the *nodes* move towards the quarters; and it is leaſt of all when the *nodes* are in the quarters, and the moon either in the conjunction or oppoſition. Newton has calculated theſe irregularities from their cauſes, and finds his concluſions agree very well with the obſervations of aſtronomers.

When the moon is in the *node*, ſhe is alſo in the ecliptic, viz. twice in each period; when ſhe is at her greateſt diſtance from the *nodes*, viz. in the points E, F, ſhe is ſaid to be in her greateſt north or ſouth latitude, according as ſhe is then on the north or ſouth ſide of the ecliptic.

The moon muſt be in or near one of the *nodes* when there is an eclipſe, either of the ſun or moon.

NODULE, NODULUS, in *Pharmacy*, a bag of medicinal ingredients put into beer, or wine, to give its tincture thereto.

Nodules are ſometimes alſo parcels of odoriferous ſimples, tied up in a piece of ſilk, for the patient to be frequently ſmelling to.

NODUS, See KNOT.

NODUS, in *Poetry*, &c. See INTRIGUE and PLOT.

NODUS, or NODE, in *Dialling*, denotes a point or hole in the gnomon of a dial, by the ſhadow or light whereof, either the hour of the day in dials without furniture, or the parallels of the ſun's declination, and his place in the ecliptic, &c. in dials with furniture, are ſhewn.

NODUS is also used for a hole in the ceiling of a room, or in the window, for the making of a dial on the floor, wall, or the like.

NOERA, a word used by some chemists for the head of an alembick, or the cover of a cucurbit, or any other vessel used in distillation.

NOETIANS, disciples of Noetus, an Ephesian, the author of Sabellianism.

They only allowed of one person in the godhead; viz. the Father; and some highly taught, that it was God the Father that suffered on the cross. An error, says Epiphanius, who wrote a hundred years after Noetus, never heard of before; though it is certain there had been other PATRIPASSIANS in the church before him.

Being reprehended by his superiors, Noetus made them this answer: What harm have I done? I adore only one God. I own none but him. He was born, suffered, and is dead.

NOFESCH, in *Natural History*, a word of Hebrew origin, used as the name of a precious stone. There has been much dispute among the commentators on the Old Testament, what stone it was. It seems derived from the word *fuch*, which signifies the ruby or carbuncle, and as the positive of that word, it must be supposed to express a red stone, but one of any other colour. As the ruby is signified by *fuch*, this cannot mean the same stone, and therefore must by means the garnet, they having no other name that we know of, for that stone, and it being very like the ruby.

NOCHETZLINOPALLI, or NOCHEZNOPATLI, in *Botany*, a name by which some authors have called the OPUNTIA, on which the cochineal insect loves to feed.

NOISETIER, in *Botany*, the name by which the French call the several species of HAZEL and filberd-trees.

NOLA, in *Botany*, a name used by some authors for the GOSSYPIUM.

NOLANA, in *Botany*, a genus of the *pentandria monogynia* class. Its characters are, that the flower is campanulated; the style is between the germina; and it has five seeds like berries, which are bilocular. There is only one species.

NOLI *me tangere*, *q. d. touch me not*, a malignant eruption in the face, occasioned by an extremely sharp corrosive humour: thus called, either because it infects those who touch it, or because the more it is touched, the worse it grows, and the further it spreads.

The *noli me tangere* is a species of HERPES *exedens*; by some referred to the CANCER, by others to the LEPROSY.

NOLI *me tangere* is chiefly used among us for an external ulcer in the ala of the nose, proceeding often from a venereal cause, though sometimes the effect of a scrophulous constitution.

It does not always confine itself to the ala, but will spread and corrode the very substance of the nose. The cure is difficult, especially when it arises from a bad constitution. M. Daniel, late acallist to the French king, observes, that abscess of the eyelids, nose, and adjacent parts, have all their rise in the periosteum and pericranium, and that we cannot hope for a thorough cure, without taking them entirely off. In this way he has succeeded in several instances, which are related in the Phil. Trans. vol. xlix. p. 18, &c.

NOLI *me tangere*, among *Botanists*, is a name of a plant so denominated from a singular property it has, of darting out its seed when ripe, upon the first approach of the hand to touch its pods. See BALSAMINE.

NOLI *me tangere*, is also a name given to the SOLANDRICA.

NOLLE *prosequi*, is used in Law, where a plaintiff in any action will proceed no further, and may be before or after a verdict, though it is usually before; and it is then a nonsuit against the plaintiff than a nonsuit, which is only a default in appearance; but this is a voluntary acknowledgment that he has no cause of action.

NOMADES, Νομάδες, from νέμω, *I feed*, a name given in *Antiquity* to several nations of people, whose whole occupation was to feed and tend their flocks; and who had no fixed place of abode, but were constantly shifting, according to the convenience of pasturage.

The most celebrated among the *Nomades* were those of Africa, who inhabited between Africa, properly so called, to the east, and Mauritania to the west. They are also called *Numidæ*, or *Nasamones*. Sallust says, they were a colony of Persians sent into Africa with Hercules.

The *Nomades* are included in the tents of the Cappadocians.

The *Nomades* of Scythia were the inhabitants of Little Tartary, who still retain the ancient manner of living.

NOMENTUM, in *Architecture*, is a space between the aliper-part and bilicy and the fore part of a triple-boat, which was laid boat is plowed upon the beams, as in a deeper-called vessel. These beams are laid from the forecastle nearly to the quarter-deck, where their ends are usually fastened by a frame called the gallows, which consists of two strong posts, about six feet high, with a cross piece, reaching from one to the other, athwart ships, and serving to support the ends of those booms, masts, and yards, which he is reserve to supply the place of others carried away, &c. The piece called *no man's land* is used to contain any blocks, ropes, &c. which may be necessary on the forecastle. It probably derives the name from its situation, as being neither on the starboard nor larboard side of the ship, nor on the waiste or gangwaies; but being situated in the middle, partakes equally of all those places. Falconer.

NOMANCY, compounded of *nomen*, *name*, and *mantia*, *divination*, a name given to the art of divining the fates of persons by means of the letters that form their names. *Nomancy*, or, as it should rather be called, *onomancy*, or *onomatomancy*, seems to be nothing else but the cabbalistic geomatria.

NOMARCHA, in *Antiquity*, the governor or commander of a nome, or nomos.

Egypt was anciently divided into several regions, or quarters, called *nomes*, from the Greek νέμω, taken in the sense of a division; and the officer who had the administration of each *nome*, or *nomos*, from the king, was called *nomarcha*, from ἀρχὴ and ἄρχω, *command*.

NOMBRIL *point*, in *Heraldry*, is the next below the *fesse* point; or the very centre of the escutcheon.

Supposing the escutcheon divided into two equal parts below the fesse, the first of these divisions is the *nombril*, and the lower the base.

NOME, or NAME, in *Algebra*, denotes any quantity with a sign prefixed, or which is to it, whereby it is connected with some other quantity; upon which the whole becomes a binomial, trinomial, or the like.

Thus $a+b$ is a BINOMIAL, whose *nomes*, or names, are a and b: and $a-b+c$ TRINOMIAL, whose *nomes* are a, b, and c, &c.

NOME, Νωμὴ, in *Medical Writers*, is used for an eating, or corroding ulcer, and is much the same with what NONNUS it occurs in Galen. Some later writers, as Forestus, call it *ulcus phagedænicum*, and *exedens ulcus*.

NOME, among the ancient Egyptians, a division or province, into which the whole kingdom was divided. The origin of the *nomes*, according to Diodorus Siculus, was this: the inhabitants being refractory, and much inclined to insurrections, in order to prevent these, the kings divided the whole country into different provinces or *nomes*, and established the worship of some particular animal in each of them, prohibiting, at the same time, such animal to be eaten within the bounds where it was worshipped. Hence, as every province was introduced with its own particular form, and object of worship, it entertained the highest contempt for that of its neighbours, and took a pleasure in profane those animals which among them had divine honours paid it. This religious opposition had the desired effect; for, all ancient writers are agreed, thereby cut off, there were no more insurrections against the government. Mem. Acad. Inscrip. vol. xiii. p. 32.

Plutarch also used for a kind of song, or hymn, in honour of the gods, said to have been invented by Terpander.

NOMEN. See PRÆNOMEN, NAME, and ADNOMEN.

NOMENCLATOR, or NOMENCLATOR, among the Romans, was usually a slave, who attended persons that stood candidates for offices, and prompted or suggested to them the names of all the citizens they met, that they might court them, and call them by their names; which among that people was the highest piece of civility.

NOMENCLATOR *of the Roman Court*, was an officer, whose business it was to call the persons whom the pope invited to dinner.

He also listened to those who were admitted to audience, in the same manner as those now retained by the cardinals, called *auditors*.

NOMENCLATORES, among the *Botanical Authors*, are those who have employed their labours about settling and adjusting the right names, synonyms, and etymologies of names, in regard to the whole vegetable world.

NOMENCLATURE, NOMENCLATURA, a catalogue of several of the more usual words in any language, with their significations, compiled in order to facilitate the use and retaining of such words to those who are to learn the tongue.

We have Latin, Greek, French, &c. *nomenclatures*.

NOMINA *villarum*, an account of the names of all the villages, and the portions thereof, in each county, drawn up by several sheriffs, at the instance of king Edward II. and returned by them into the exchequer, where it is still preserved.

NOMINAL *computers*. See CHARACTER.

NOMINALS, or NOMINALISTS, a sect of school-philosophers, the disciples and followers of Occam, or Ockam, an English Cordelier, in the fourteenth century.

The *Nominalists* were great dealers in words, whence they were vulgarly denominated *sophisters*.

They had the denomination *Nominalists*, because, in opposition to the REALISTS, they maintained, that words, not things, were the object of dialectics.

This sect had its first rise towards the end of the eleventh century, and pretended to follow Porphyry and Aristotle; but it was not till Ockam's time that they bore the name. The chief of this sect in the eleventh century, was a person called John, who, on account of his logical subtilty, was called the Sophist, and his principal disciples were Robert of Paris, Roscelin of Compiegne, and Arnoul of Laon. At the beginning, the *Nominals* had the upper hand: but the Realists, though greatly divided among themselves, were supported by men of great abilities; such as Albertus Magnus, T. Aquinas, and Duns Scotus. The *Nominal* sect became hereby into disrepute; till William Ockam, in the fourteenth century again revived it, and filled France and Germany with the flame of disputation. Having joined the party of the Franciscan monks, who strenuously opposed John XXII. that pope himself, and his successors after him, left no means untried to extirpate the philosophy of the *Nominalists*, which was deemed highly prejudicial to the interests of the church: and hence it was, that, in the year 1339, the university of Paris, by a public edict, solemnly condemned and prohibited the philosophy of Ockam, which was that of the *Nominalists*. The consequence was, that the *Nominalists* flourished more than ever. In the fifteenth century, the controversy was continued with more vigour and animosity than ever; and the disputants were not content with using merely the force of eloquence, but had frequently recourse to more hostile and dangerous weapons; and battles were the consequence of a philosophical question, which neither side understood. In most places, however, the Realists maintained a manifest superiority over the *Nominalists*. While the famous Gerson, and the most eminent of his disciples were living, the *Nominalists* were in high esteem and credit in the university of Paris. But upon the death of these patrons, the face of things was much changed to their disadvantage. In the year 1473, Lewis XI. by the instigation of his confessor, the bishop of Avranches, issued out a severe edict against the doctrines of the *nominalists*, and ordered all their writings to be seized and secured, that they might not be read by the people: but the same monarch mitigated this edict the year following, and permitted some of the books of that sect to be delivered from their confinement. In the year 1481, he not only granted a full liberty to the *Nominalists* and their writings, but also restored that philosophical sect to its former authority and lustre in the university. Mosheim, vol. iii. p. 222. 8vo. Eng. ed.

The *Nominalists* were the founders of the university of Leipsic: there are many yet abroad, who pique themselves on being *Nominals*.

The *Nominals*, with the Stoics, admit the formal conceptions or ideas of things, as the subject and foundation of universality; but to this they add names, which represent and signify, after the same univocal manner, and without any distinction, a great variety of single things alike in genus and species.

Whence it is that they are called *Nominals*; as pretending, that to become learned, it is not enough to have just ideas of things, but it is likewise required to know the proper names of the genera and species of things, and to be able to express them clearly and precisely, without confusion or ambiguity.

NOMINATION, the act of naming and appointing a person for some function, employ, or benefice.

The word is chiefly used for the right of presenting to a benefice, &c.

In common law, however, there is a difference between *nomination*, and PRESENTATION; the former being properly a power which a man has, by virtue of a manor, or otherwise, to appoint or name a clerk to a patron of a benefice, to be by him presented to the ordinary.

NOMINATIVE, in *Grammar*, the first case of nouns which are declinable.

The simple position, or laying down of a noun, or name, is called the *nominative case*: yet is it not so properly a case, as the matter or ground whence the other cases are to be formed, by the several changes and inflexions given to this first termination. See CASE.

Its chief use is to be placed in discourse before all verbs, as the subject of the proposition, or affirmation, as, *Dominus regit me*, the *Lord governs me*; *Deus exaudit me*, *God hears me*.

NOMINATOR, he who names or presents a person to an office, or benefice.

Hence *nominee*, the person named or presented.

Extard observes, that there are some customs where the *nominator* is responsible for the solvibility of the nominee.

NOMINE *pœnæ*, in *Law*, is a penalty incurred for not paying rent, &c. at the day appointed by the lease or agreement, for the payment thereof.

NOMINIS *identitate*. See IDENTITATE.

NOMOCANON, compounded of νομος, *law*; and κανων, *canon*, or *rule*, a collection of canons, and of imperial laws relative or conformable thereto. See CANON.

The first *nomocanon* was made by Johannes Scholasticus, in 554. Photius, patriarch of Constantinople, in 883, compiled another *nomocanon*, or collation of the civil laws with the canons: this is the most celebrated. Balsamon wrote a commentary on it, in 1180.

NOMOCANON also denotes a collection of the ancient canons of the apostles, councils, and fathers; without any regard to imperial constitutions.

Such is the *nomocanon* published by M. Cotelier.

NOMOCANON is sometimes also used for a PENITENTIAL book of the Greeks.

NOMOPHYLACES, Νομοφυλακες, among the Athenians, magistrates who were to see the laws executed, being not unlike to our sheriffs. They had the execution of criminals committed to their care, as also the charge of such as were confined prisoners. They had also power to seize thieves, kidnappers, and highwaymen, upon suspicion; and, if they confessed the fact, to put them to death: if not, they were obliged to prosecute them in a judicial way.

NOMOPHYLACES were likewise officers belonging to the Olympic games, whose business it was to instruct those who were to contend, in all the laws of the games. See HELLENODICÆ.

NOMOTHETÆ, Νομοθεται, among the Athenians, were a thousand in number, and chosen by lot out of such as had been judges in the court *Heliæa*. Their office was not (as their name seems to imply) to enact new laws by their own authority, for that could not be done without the approbation of the senate, and the people's confirmation; but to inspect the old, and, if they found any of them useless, or prejudicial, as the state of affairs then stood, or contradictory to others, they caused them to be abrogated by an act of the people. Beside this, they were to take care that no man should plough or dig deep ditches within the Pelasgian wall; to apprehend the offenders, and send them to the archon.

NO *more*, in *Sea-Language*, is the command given by the pilot or quarter-master, to the helmsman, to steer the ship *no nearer* to the direction of the wind than the sails will operate to advance the ship in her course.

NON-ABILITY, in *Law*, an exception taken against the plaintiff in a cause, on some just ground why he cannot commence a suit in law: as pronunire, outlawry, being professed in religion, excommunicate, or a stranger born. This last holds only in actions real, and mixed; and not in personal, except he be both a stranger, and an enemy. The civilians say, that such a man hath not *personam standi in judicio*. See DISABILITY.

NON *admittas*. See NE-*Admittas*.

NON-APPEARANCE, a default in not appearing in a court of judicature. See APPEARANCE.

NON *assumpsit*, in *Law*, a plea in personal actions, whereby a man denies any promise made, &c. or that he made any such promise within six years, which is an effectual bar to the complaint.

NON-CLAIM, in *Law*, the omission or neglect of him who challenges not his right within the time limited by law: as, within a year and a day, where continual claim ought to be made.

By such neglect he is either barred of his rights as upon *non-claim* within five years after a right accrued to him; or of his entry by descent, for want of a *claim* within five years after the disseisin.

NON *compos mentis*, a phrase denoting a person not to be of sound memory, or understanding.

Of this, in common law, there are said to be four kinds. First, an IDIOT born; secondly, he that by accident loseth his memory, and understanding; thirdly, a LUNATIC, that has *lucida intervalla*, sometimes understanding, and sometimes not; fourthly, he that by his own act, for a time, depriveth himself of his right sense, as a drunkard. But this last kind shall give no privilege to him, or his heirs.

A descent takes away the entry of an idiot, though the want of understanding were perpetual.

NON-CONFORMISTS is a general denomination comprehending all those who do not *conform* to the established worship of the church. These are of two sorts, viz. 1. Such as absent themselves from it through total irreligion, and attend the service of no other persuasion; who by 1 Eliz. cap. 2. 23 Eliz. cap. 1. and 3 Jac. I. c. 4. forfeit one shilling to the poor, every Lord's day they so absent themselves, and 20*l.* to the king if they continue such default for a month together: and if they keep any inmate thus irreligiously disposed, in their houses, they forfeit 10*l.* per month. And 2. Such as absent themselves from the worship of the established church, under the plea of conscience; and these are *Protestant* DISSENTERS, to whom the term is commonly applied, and PAPISTS. See also TOLERATION.

The word is said to have had its rise from a declaration of King Charles I. who appointed that all the churches of England and Scotland should have the same ceremonies and discipline; the acquiescence whereto, or dissenting from which, determined *conformity* and *non-conformity*. But this distinction primarily related to the rites of worship and ecclesiastical laws, enacted by Edw. VI. Those who complied with them were *Conformists*, and those who object *Nonconformists*. See PURITANS.

NON *damnificatus*, in *Law*, is a plea to an action of debt upon a bond, with condition to save the plaintiff harmless. Abr. 224. If the condition of a bond be to save harmless only, *non damnificatus* generally is a good plea; but if it be to discharge the plaintiff, &c. then the manner of the discharge is to be shewn.

NON *decimando*. See MODUS *decimandi*.

NON *distringendo*, a writ not to distrain, used in divers cases.

NON *est culpabilis*, NON *cul.* q. d. *he is not guilty*, in *Law*, the general plea in an action of trespass, whereby the defendant absolutely denies the fact charged on him by the plaintiff: whereas, in other special pleas, the defendant grants the fact to be done, but alledges some reasons in his defence, why he lawfully might do it.

As *non cul.* is the general answer in an action of trespass, i. e. a criminal action civilly prosecuted; so is it in all actions criminally followed, either at the suit of the king, or others, wherein the defendant denies the crime objected to him.

NON *est factum*, in *Law*, is an answer to a declaration, whereby a man denieth that to be his bond or deed, whereupon he is impleaded.

NON *est inventus*, in *Law*, is the sheriff's return to a writ, when the defendant is not to be found in his bailiwick. And there is a return that the plaintiff, *non invenit plegium*, on original writs. Shep. Epit. 1129.

NON *implacitando aliquem de libero tenemento sine brevi*, a writ to prohibit bailiffs, &c. from distraining any man touching his freedom, without the king's writ.

NON *intromittendo quando breve præcipe in capite sibidolu impetratur*, a writ directed to the justices of the bench, or in eyre, commanding them not to give one that had, under colour of inditing the king to land, &c. as holding of him *in capite*, deceitfully obtained, the writ called *præcipe in capite*, any benefit thereof, but to put him to that writ of right. Reg. Orig. 4. This writ having a dependence on the *court of wards*, since taken away, is now disused.

NON *juridici dies*. See DIES.

NON-JURORS, are persons that refuse to take the oaths to the government, who are liable to certain penalties; and for a third offence to abjure the realm, by 13 and 14 Car. II. cap. 1. Parsons, vicars, &c. are to take the oaths, and give their assent to the declaration. 14 Car. II. cap. 4. or they shall not preach, under the penalty of 40*l.* &c. stat. 17 Car. II. cap. 2. Ecclesiastical persons not taking the oaths on the Revolution, were rendered incapable to hold their livings: but the king was impowered to grant such of the *nonjuring* clergy as he thought fit, not above twelve, an allowance out of their ecclesiastical benefices for their subsistence, not exceeding a third part. 1 W. and M. sess. 1. cap. 8. persons refusing the oaths, shall incur, forfeit, and suffer, the penalties inflicted on Popish recusants, and the court of exchequer may issue out process against their lands, &c. 7 and 8 Will. III. cap. 27. See the stat. 1 Geo. I. cap. 53. and OATHS.

The *Non-jurors*, or high-church men, were particularly distinguished by the following principles: 1. They maintained the doctrine of PASSIVE *obedience*. 2. That the hereditary succession to the throne is of divine institution, and, therefore, can never be interrupted, suspended, or annulled, on any pretext. 3. That the church is subject to the jurisdiction, not of the civil magistrate, but of God alone, particularly in matters of a religious nature. 4. That, consequently, the bishops deposed by king William III. remained, notwithstanding their deposition, true bishops to the day of their death; and that those who were substituted in their places were the unjust possessors of other men's property. 5. That these unjust possessors of ecclesiastical dignities were rebels against the state, as well as schismatics in the church, and that all, therefore, who held communion with them were also chargeable with rebellion and schism. And, 6. that this schism, which rends the church in pieces, is a most heinous sin, whose punishment must fall heavy on all those who do not return sincerely to the true church, from which they have departed. See *High Church*.

NON *liquet*, *it does not appear*, a VERDICT given by a JURY, when a matter is to be deferred to another day of trial.

The same phrase was used among the Romans: after hearing a cause, such of the judges as thought it not sufficiently clear to pronounce upon, cast a ballot into the urn with the two letters *N. L.* for *non liquet*.

NON *merchandizandis victualia*, a writ to justices of assize to enquire whether the magistrates of such a town do sell victuals in gross, or by retail, during the time of their being in office, which is contrary to an ancient statute, and to punish them if they do. Reg. Orig. 184.

NON *molestando*, a writ which lies for him who is molested contrary to the king's protection granted him.

NON *obstante*, *notwithstanding*, in *Law*, a clause frequent in statutes, and letters patent; importing a licence from the king to do a thing, which at common law might be lawfully done; but being restrained by act of parliament cannot be done without such licence.

All grants of such pensions, and every *non obstante* therein contained, shall be void. Henry III. took up the clause, *non obstante* (first introduced by the pope), in his grants.

But the doctrine of *non obstantes*, which sets the prerogative above the laws, was effectually demolished by the bill of RIGHTS at the Revolution, and abdicated Westminster-hall when king James abdicated the kingdom. It is enacted by 1 W. and M. sess. 2. cap. 2. that no dispensation by *non obstante*, of or to any statute, or any part thereof, shall be allowed; but that the same shall be held void and of none effect, except a dispensation be allowed in such statute.

NON *obstantes*, in the *Romish Canon-law*, make the third part of the provisions of the court of Rome, beginning with *Non obstantibus*, and comprising absolutions from censures, rehabilitations, and necessary dispensations for the enjoyment of benefices. None inferior to the pope can use the clause *Non obstante*.

NON *omittas*, a writ which lies where the sheriff having delivered a writ or process to a bailiff of a franchise in which the party it is to be served on dwells, and the bailiff having refused or neglected to serve it, upon the sheriff's returning, that he delivered it to the bailiff, this second writ shall be directed to the sheriff, charging him to enter the franchise, and execute the king's command, either by himself or officer.

NON PLEVIN, *non plevina*, a default in not replevying of land in due time. See REPLEVIN.

In *Hengham Magna*, it is said, that the defendant should be sure to replevy his lands seized by the king, within fifteen days; and that if he neglects, then, at the instance of the plaintiff at the next court-day, he shall lose his seisin, *sicut per defaltam pro defaltam*. But, by stat. 9 Edw. III. it was enacted, that no person should lose his land thenceforward because of *non plevin*.

NON *ponendo in assisis, & juratis*, a writ granted on divers occasions to men for freeing them from serving on assizes and juries; as by reason of old age, charter of exemption, or the like.

NON *procedendo ad assisam rege inconsulto*, a writ to stop the trial of a cause appertaining to one who is in the king's service, &c. till the king's pleasure be farther known.

NON *residence*, in *Law*, is applied to such spiritual persons as are not resident on, but absent themselves, for one month together, or two at several times of the year, from their benefices or dignities. See BENEFICE.

Regularly, personal residence is required of ecclesiastical persons upon their cures; though there are some exceptions in favour of particular persons, as king's chaplains, bishops, &c. See RESIDENCE.

NON *residentia pro clericis regis*, is a writ directed to the ordinary, charging him not to molest a clerk employed in the king's service, on account of his *non-residence*.

NON *sanæ memoriæ*, or NON *sanæ memoriæ*, is an exception taken to an act declared to be done by another, importing that it was done at a time when the party that did it was mad, or not in his proper senses. See NON *compos*.

NON *sciffum*, in the *Ancient Musse*. See APTENON.

Non-such clay, a particular sort of earth, which, mixed with another clay brought from Worcestershire, makes a composition very useful for making the melting-pots used in the green glass making.

NON-SUIT, in *Law*, the dropping or letting fall a suit or action. *Non-suit* is a renunciation of a suit, by the plaintiff or defendant; most commonly upon the discovery of some error, or defect, when the matter is so far proceeded in, as that the jury is ready at the bar, to deliver their verdict. The civilians term it *litis renunciatio*.

When the plaintiff is voluntarily *non-suited*, or withdraws himself, the crier is ordered to *call the plaintiff*; and if neither he nor any body for him appears, he is *non-suited*, the jurors are discharged, the action is at an end, and the defendant shall recover his costs. A *non-suit* is more eligible for a plaintiff than a verdict against him and judgment

judgment, because in the former case he may commence the same suit again for the same cause of action; but in the latter he is for ever barred from attacking the defendant on the same ground of complaint. See JURY.

NON *cepit informatus, non, &c.* See INFORMATUS *non, &c.*

NON-TENURE, a plea in bar to a real action, whereby the party urges, that he holdeth not the land mentioned in the writ, or at least some part of it.

Writ distinguished *non-tenure into general and special.* The first, where one denies himself ever to have been tenant to the land in question. The second, where he only alledges, that he was not tenant on the day whereon the writ was purchased.

NON-TERM, the time of vacation between term and term. See VACATION.

It was anciently called *the time or days of the king's peace.* See PEACE *of God and the church.*

Among the Romans it was called FERIÆ, or *dies* NEFASTI.

NON-ENTITY, whatever has no real being, or is only conceived negatively, or claims only a negative denomination. See ESSE, ESSENCE, &c.

NON-ESSENTIAL *modes.* See MODES.

NON-NATURALS, in *Medicine*, *res non naturales*, are the causes and effects of diseases, whether near or remote.

Physicians have digested all the causes of diseases into six classes, which they call the six *non-naturals.* These are,

1. Air. 2. Meat and drink. 3. Motion and rest. 4. The passions of the mind. 5. Excretions and retentions. 6. Sleep and waking. See each under its proper article.

They are thus called, because, by their use or abuse, they become either good, *naturals*; or evil, *contra-naturals.*

But the division is of no great use; the causes of diseases being much more commodiously laid down otherwise.

NONÆ and *decimæ* were payments anciently made to the church by those who were tenants of church-farms.

The *nonæ* were a rent or duty claimed for things belonging to husbandry: the *decimæ* were claimed in right of the church.

NONAGE, in *Law*, an incapacity of doing certain things from a want of age.

The term of *nonage* is different, with regard to different things. In matters of inheritance, a man is in his *nonage* till twenty-one years; for marriage only to fourteen, &c. See AGE and MINOR.

NONAGE, NONAGIUM, also denotes the ninth part of a man's moveable goods, anciently paid in the nature of a MORTUARY; being claimed by the clergy upon the death of those of their parish.

At first this was a third part of the goods, and was called *tertiarium*; till by a bull of Clement VI. it was reduced to a ninth.

NONAGESIMAL, in *Astronomy*, the nineteenth degree of the ecliptic, reckoned from its eastern term, or point.

The altitude of the *nonagesimal* is equal to the angle of the east; and, if continued, passes through the poles of the ecliptic: whence the altitude of the *nonagesimal*, at a given time, under a given elevation of the pole, is easily found.

If the altitude of the *nonagesimal* be subtracted from 90°, the remainder is the distance of the *nonagesimal* from the vertex.

NONAGON, a figure having nine angles and sides.

NONE, or NONES, *Nonæ*, one of the seven canonical hours, in the Romish church. See HOUR.

Nine, or the ninth hour, is the last of the lesser hours, that is said before vespers; and answers to three o'clock in the afternoon.

The single office, and that for the dead, ends at *nones*; which, Father Rosweyd observes, was anciently the hour for the breaking up of the synaxis, or usual meetings at church of the primitive Christians.

The hour of *none* was also the usual time for taking the repast on fast-days; though some would keep the fast till night.

NONE *leperty*, in *Botany*. See SAXIFRAGE.

NONE *fuch*, in *Botany*. See CAMPION.

NONES, NONÆ, in the *Roman Calendar*, the fifth day of the months January, February, April, June, August, September, November, and December; and the seventh of March, May, July, and October: these four last months having six days before the *Nones*, and the others only four.

The word apparently has its rise hence, that the day of the *nones* was nine days before the ides, and might be called *nono-like.*

March, May, July, and October, had six days in their *nones*; because these alone, in the ancient constitution of the year by Numa, had thirty-one days a-piece; the rest having only twenty-nine, and February thirty. But when Cæsar reformed the year, and made other months contain thirty-one days, he did not likewise allot them six days of *nones.*

NONIUS, is a name erroneously given to the method of graduation now generally used in the division of the scales of various instruments, and which should be called VERNIER, from its real inventor. The method of *Nonius*, so called from its having been invented by Pedro Nunez, or *Nonius*, and described in his treatise de Crepuscules, printed at Lisbon in 1542, consists in describing within the same quadrant, forty-five concentric circles, dividing the outermost into ninety equal parts, the next within into eighty-nine, the next into eighty-eight, &c. till the innermost was divided into forty-six only. By this means, in most observations, the plumb-line or index must cross one or other of the circles very near a point of division: whereon by computation, the degrees and minutes of the arch might be easily computed. This method is also described by Nonius, in his treatise De Arte atque Ratione Navigandi, lib. 2. cap. 6. where he would persuade himself, that it was not unknown to Ptolemy. But as the degrees are thus divided very unequally, and it is very difficult to attain exactness in the division, especially when the numbers, into which the arches are to be divided, are incomposite, of which there are no less than nine, the method of diagonals, first published by Thomas Digges, esq. in a treatise intitled *Alae seu Scalæ Mathematicæ*, printed at London, in 1573, and said to be invented by one Richard Chancellor, a very skilful artist, was substituted in its room. However *Nonius*'s method was improved at different times; but the admirable division now so much in use, is the most considerable improvement of it.

NONUPLA, in the *Italian Music*, denotes a quick time, peculiar to jigs. This species of time is otherwise called *the measure of nine times*, which requires two falls of the hand, and one rise. There are three sorts of *nonupla*. 1. *Nonupla di semi-minime*, or *dupla sesqui quarta*, thus marked $\frac{9}{8}$, where nine crotchets are to be to the bar, of which four make a semi-breve in common time, i.e. in the down stroke, $\frac{4}{4}$, and but three up; it is usually beat *adagio*. 2. *Nonupla di crome*, or *sesqui ottava*, marked thus $\frac{9}{16}$, wherein nine quavers make a bar, instead of eight in common time, i. e. six down, and three up: it is beat *presto*. 3. *Nonupla di semi-crome*, or *super sesti partiente nona*, thus distinguished $\frac{9}{32}$, in which nine semi-quavers are contained in a bar, whereof sixteen are required in common time, six down, and three up: it is ordinarily beat *prestissimo*. See ADAGIO, PRESTO, and PRESTISSIMO.

Beside these, there are two other species of *nonupla*, for which see TRIPLE.

NONUS *humeri platysmini*, in *Anatomy*, a muscle, called also ROTUNDUS *minor*.

NOOK *of land*, *nocata terra*, in an old deed of Sir Walter de Pedwardyn, twelve acres and a half of land were called a *nook of land*; but the quantity is generally uncertain.

NOOZE, a name given by sportsmen to a sort of horse-hair springe made to take woodcocks, and very successful, when the proper precautions are taken. The *nooze* is made of several long and strong hairs twisted together, with a running *nooze* at one end, and a large knot at the other, which is to be pulled through the slit of a cleft stick, to prevent the *nooze* from being pulled away when the bird is caught in it.

The sportsman, when he knows his business, does not stay to watch these snares, but sets them in the morning, and returns again to them at four in the afternoon, when he seldom fails of meeting with a sufficient number taken. The sticks are to be about the bigness of a man's little finger, and are to be made sharp at one end, that they may fix the better in the ground: to each of these is to be fixed one *nooze*. The sportsman is to take out with him several dozens of these bundled up together, and going into the coppice woods where there lie many leaves upon the ground, he is to search among these for the marks of woodcocks frequenting the place; if there come any there, it will soon be found out by the leaves, which are spread about from side to side by their bills, in searching under them for worms. Their dung also, which is of a dark grey colour, being found about the place, is a proof of their frequenting it.

When the place is thus pitched upon, the sportsman is to take a large circle at some distance from it, on each side, in the way where the woodcocks are supposed to come to the place; he is here to plant a small hedge-row of furze, or other bushes, of a considerable extent, and pretty thick, leaving gaps in it here and there. The

woodcocks, in making up to their place of feeding, when they come to this hedge, will run along by the side of it, till they come to one of the gaps, and then go through, for they hate to take wing, and will run, at any time, a long way under a hedge, rather than fly over it. On this depends the success of the sport.

The *nooses* are to be fixed one in each of these gaps through which it is known the woodcocks will pass; the stick to which it is fastened is to be stuck firmly in the ground, and the *noose* to be spread wide open on the ground, leaving only some dry leaves to support it. The whole gap being occupied by this *noose*, the woodcock, when he comes, cannot easily escape being taken by the legs in it, and when once caught he will lie till the sportsman comes. While a sportsman is walking about a wood in this view, it is very common for him to find springes, or *nooses*, of horse-hair, fixed at six inches high, in several places. This may be looked on as a proof that these are partridges in the wood, and these are the means used by the country people to take them. The woodcocks, though in the day they lie in woods, *set*, in the night, they go out, and frequent rivers and brooks, and, in the frosty nights, such springs as do not freeze are particularly resorted to by them.

The sportsman, when he has set his *nooses* in the woods for the day time, should retire to the watery places near them, and search for the marks of these birds coming to them by their dung, and other tokens. As soon as a place is found which they frequent, there must be a small hedge-row built there also in the same manner as in the woods; and in the gaps, which are to be made at the distance of about six feet one from another, there are to be placed either the same sort of *nooses* as those in the woods, or the springes made with hazel boughs, and the horse-hair tied to a pack-thread. In either case, there is no doubt of success, for the birds which have once frequented a place, will come to it every night, as long as they remain any where near it; but particularly, if there be any spring near a wood, the water not freezing when other waters are iced over, will be sure to bring the woodcocks together to it, and *nooses* planted properly about this place, will seldom fail of success. If they have been left a night or two without success, the sportsman is not to despair; for though there should happen to be no woodcocks there when they are first set, these birds change place so often, that it need not be doubted but so proper a rendezvous will be soon resorted to by them.

NOPE, in *Ornithology*, an English name used by some for the BULL-*finch*.

NORA, a word used by some of the chemical writers for *lixa*, by others *for nitre*, and by others for all salts in general, as the word *sal*.

NORMAL *line*, in *Geometry*, is used for a perpendicular line. See PERPENDICULAR, and NORMAL.

NORMAN, in *Sea-Language*, a name given to a short wooden bar, thrust into one of the holes of the windlass, in a merchant ship, whereon to fasten the cable. It is only used where there is very little strain on the cable, as in a commodious harbour, when the ship is well sheltered from the wind and tide.

NORMANNORUM *terra*. See TERRA.

NORROY, *North Roy*, q. d. Northern king; the title of the third of the three kings at arms, or provincial heralds. See KING *at Arms*, and HERALD.

His jurisdiction lies on the north side of Trent, whence his name; as Clarenceux, on the south.

NORTH, in *Geography*, one of the four cardinal points of the horizon, being that intersection of the horizon and meridian which is nearest our pole.

NORTH *latitude of the moon*. See LATITUDE.

NORTH *compass*. See COMPASS.

NORTH *sea*. See DIAL.

NORTH-*east*, a rhumb, or point, in the middle between the east and north.

NORTH-*north-east*, *north-east-by-east*, are subdivisions of the compass between the *north* and *east*. See WIND.

NORTH-*east passage*. The advocates for the *north-east* passage, have a late writer, have divided that navigation into three parts; and by endeavouring to shew that these three parts have been passed at different times, they conclude from thence, that the whole taken collectively, is practicable. These three parts are, 1. From Archangel to the river Lena. 2. From the Lena round Tschukotskoi Noss, (or the north-eastern promontory of Asia) to Kamchatka: and 3. From Kamchatka to Japan. With respect to the first part, no one ever affirmed, that it has been performed in one voyage: from an account of the several voyages that have been made in these seas, it appears, that there is a cape between the rivers Chatanga and Pasida, that has never yet been doubled. As to the second division of the *north-east passage*, it has been affirmed, that a passage has been effected by several vessels, which have, at different times, sailed round the northern extremity of Asia. But from the Russian accounts it is inferred, that it has been performed but once, viz. by one Dethneff, who, in 1648, is said to have doubled this formidable cape. Of the third, or remaining part of this passage, no doubt can be entertained. The connection between the seas of Kamtschatka and Japan has been established by many voyages. Coxe's Account of the Russian Discoveries, &c. 4to. 1780.

NORTH *pole*. See POLE.

NORTH *sea*. See SEA.

NORTH *star*, the last in the tail of the Little Bear; called also the POLE-*star*.

NORTH *wall*. See WALL.

NORTH-*west*, is a point or rhumb, in the middle between the *north* and west. See WEST, &c.

NORTH-*west passage*. A *north-west passage* by Hudson's-bay, into the Pacific Ocean has been more than once attempted of late years, but, hitherto, without success. Some greatly doubt of the practicability of such an enterprize, and think the observations made by the Russians give us small hopes. But, as they have not yet published the particulars of their discoveries, little can be said about them. Some general things may be seen in the Phil. Transf. N° 482. sect. 14. It appears from thence, that the Russians have passed between the land of Nova Zembla, and the coast of Asia, and, as the Dutch did formerly discover the northern coasts of Nova Zembla, we may now be well assured, that that country is really an *island*.

NORTH-*wind*. See WIND.

NORTHERN *aspect*, or EXPOSURE. See EXPOSURE.

NORTHERN *lights*, or *Aurora Borealis*. See AURORA *Borealis*.

NORTHERN *ocean*. See OCEAN.

NORTHERN *signs* are those fix on the *north* side of the equator. See SIGN.

NORTHERN *hemisphere*. See HEMISPHERE.

NORTHING, in *Navigation*, the difference of latitude, which a ship makes in sailing towards the *north pole*.

NORWAY *rat*. See *Sable* MOUSE and RAT.

NOSE, the *external* organ of smelling; or that part in man which stands prominent, in the middle of the face.

The *nose* is usually divided by anatomists into *external* and *internal*; a division of very little service.

It is further subdivided into several parts, which make up its external figure.

The first is the *dorsum*, or ridge, running along the whole length of it; one part whereof, about the middle, more prominent than the rest, is called the *apex*; and the extreme, which in many is turned round, *orbiculus*. The sides are called the *alæ*, or *pinnæ*.

The organments of the *nose* are common to the rest of the face. Under these appear the muscles of the *nose*, which are three pair, viz. the *elevatores alæ nasi*, serving to pull the *alæ* upwards, and turn them outwards; the *depressores alæ nasi*, which draw them from each other, and widen the external apertures of the nostrils; and the *constrictores alæ nasi*, which draw them downwards nearer each other; and at the same time the upper lip also downwards. See each muscle described under its proper head, ELEVATOR, DILATATOR, &c.

The frame of the *nose* is chiefly supported by two bones, which end in cartilages of a triangular figure, and are divided in the middle by the third, called *septum*, into two partitions, called the *nares*, or NOSTRILS.

This septum likewise ends in a cartilage, by means of which cartilages, the lower part of the *nose* is rendered moveable, which the upper, being perfectly osseous, is not. The cartilages of the *alæ* are tied to the others by ligaments; which loose connexion renders them moveable.

The bones of the *nose* are either *proper* or *common*. The first of the *proper*, are the two external ones that constitute the dorsum, and are joined to the *ossa frontis*, the fourth bone of the upper jaw, and to each other, partly by sutures, and partly by harmony.

In the concave of the arch of these two bones, at their union internally, is placed the bony part of the septum. Its upper part joins the *os ethmoides*; but in adults is continued to that the ethmoides, and its process, called *crista galli*, appear of a piece with the septum. The *septum* is thinner in the middle, and divides the right nostril from the left; though its position is seldom perpendicular. It is capped with another thin bone, from its figure called *vomer anterius*, and is joined to the fourth bone of the upper jaw, and to the *ossa palati*.

The other proper bones are the *turbinata*, or *spongiosa*, two of which are usually found in each nostril, sometimes three, placed one over the other.

The middlemost, when there are three, is so placed as to

shelter the perforation of the antrum maxillæ superioris into the noſtril, and prevent the ſolden noſhing in of air from the noſtril into the antrum. They are all very porous, and turned, not unlike the ſhell concha Veneris. In quadrupeds, theſe bones are very numerous.

The common bones of the noſe are ſuch as make fences for the foramina narium, and help to compoſe the parts adjacent. The largeſt of theſe is the fourth bone of the upper jaw, which has the greateſt ſhare in forming the foramina.

This fourth bone, with the ſeptum and oſſa turbinata, chiefly frames the internal parts of the foramina. In the upper part, a portion of the os frontis, the inſide of the os unguis, the os tribroſum, with part of the ſphenoides; and backwards, towards the fauces, the oſſa palati help to compoſe the foramina.

Beſides the cavities circumſcribed by the bones now mentioned, the foramina have ſeveral collateral cavities that open into them: the largeſt is that called *antrum genæ*; by Dr Highmore, *antrum maxillæ ſuperioris*, framed in the fourth bone of the upper jaw, near two inches long, and an inch broad; the bony parts of which, with the ſphenoides, make the foramen lacerum externum. Its lower ſurface makes a thin covering for all the roots of the molares and canini, which frequently, upon drawing a tooth, to which it ſticks, is taken along with it; whereby this cavity is opened into the alveolus, and conſequently into the mouth.

All theſe cavities of the *noſe* and cheek, as alſo the oſſa turbinata, ſeptum, &c. are inveſted with a membrane furniſhed with large arteries from the carotides; and veins, which empty themſelves into the jugulars; and nerves, from the fifth pair, as well as the olfactory nerves.

In this membrane are a great number of ſmall glands, placed very near each other, from whence flows all that pituita, commonly diſcharged at the noſtrils.

By means of this mucus or pituita is the membrane kept ſoft, and defended from the injuries of extraneous bodies, eſpecially thoſe of the air, which muſt paſs this way in inſpiration, when the mouth is ſhut.

By this means alſo the olfactory nerves, here diffuſed, are rendered capable of the perception of odoriferous effluvia, which the drineſs of the part would be apt to deſtroy. See SMELLING.

Beſides this uſe of the *noſe*, which is the principal, nature has made it, as it were, a diverticulum to the eyes; there being a conſiderable paſſage into each noſtril that empties itſelf under the middle os turbinatum, ariſing from two apertures, called *puncta lacrymalia*, at the great canthus.

By this way, the ſuperfluous moiſture of the eyes is carried off, which would otherwiſe incommode the cheeks; as in effect it does, when theſe parts are affected with any diſorder; as in the ægilops, and fiſtula lacrymalis.

The diſeaſes to which the *noſe* is ſubject, are a coryza, ozæna, polypus, ſarcoma, and noli me tangere, beſide ſneezing, and a loſs of ſmelling. See each in its place.

In Tartary, the greateſt beauties are thoſe who have the leaſt *noſes*. Raybrock mentions the wife of the great Genghis Khan, the mother of Tamerlane, as a celebrated beauty, becauſe ſhe had only two holes for a *noſe*. In moſt other countries, China excepted, great *noſes* are in honour.

The Crim Tartars break the *noſes* of their children while young, as thinking it a great piece of folly to have their *noſes* ſtand before their eyes.

NOSE, *bleeding at the*. See HEMORRHAGE.

NOSE, *cutting off, or ſlitting the*, in *Law*. See MAIHEM.

NOSE, *fracture of the*. In the *noſe* both bone and cartilage are ſubject to fractures, which happen ſometimes on either ſide, and ſometimes in the middle from blows or falls; if either of the bones on the front of the *noſe* are fractured, it produces a flatneſs in the *noſe*, and the air meets with obſtructions in its paſſage through the noſtrils; and if the bone on either ſide is fractured, the part becomes hollow. When the cartilage is diſturbed, the *noſe* inclines too much on one ſide. Theſe fractures ſometimes happen without a wound, but more uſually they are attended with a wound of the common integuments. If the injury of the *noſe* is very great, the fracture can never be ſo perfectly cured, but that ſome deformity will remain. The vicinity of this part to the brain alſo, which is frequently injured at the ſame time, renders caſes of this kind often dangerous. A caries alſo, or an ozæna, or polypus, are no uncommon attendants on this diſorder. In order to reſtore the bones of the *noſe* to their proper ſituation, the patient is to be placed in a ſtrong oppoſite to the light, and his head held back by an aſſiſtant. The ſurgeon is to raiſe the depreſſed parts with a ſpatula, a probe, or a quill, applying externally the thumb of one hand, and the fore-finger of the other. If the bones of the *noſe* are fractured on both ſides, they are to be raiſed on each in this manner, and the cavity of the noſtrils is to be filled up with long doſſils, to prevent the bones from collapſing; covering the part alſo for this end with ſome plaiſter, and applying firſt the dreſſings common in recent wounds. If the bone is fractured into ſeveral ſplinters, they are to be reduced into their proper places by the fingers; but if a ſplinter is ſo entirely ſeparated from the bone, that it will not eaſily unite with it again, it is to be taken out with the forceps. The bones will unite, when properly replaced, in about fourteen days, if no caries, or abſceſs, intervene. If the bone ſhould require a ſtronger ſupport than what has been hitherto mentioned, one may be formed out of ſtrong paper, either ſingle or double, and adapted to each ſide of the *noſe*, and ſupported by doſſils, and the whole muſt be kept in its place by a four-headed bandage not tied too tight. Heiſter.

NOSE, *ſaddle*. It ſometimes happens, though not often, that the bones of the *noſe* are ſeparated from each other, or diſtorted out of their natural places, without a fracture. When this caſe happens, the patient is to be ſpeedily placed in a high chair, and an aſſiſtant muſt ſtand behind, and hold his head firm in a proper poſture: the ſurgeon is then to introduce with one hand a thick probe, a gooſe quill, or a ſmall ſtick ſhaped for that purpoſe up the noſtril internally, by which means the depreſſed parts of the *noſe* may be thruſt out into their places: in the mean time he is to apply his other hand externally, to guide and direct the parts which are thus moved from within. This being done, and the bones properly replaced, there is ſcarce any thing elſe to be done, but to let a piece of ſticking plaiſter lie upon the *noſe* for ſome time. Heiſter.

NOSE, *wounds of the*. Wounds of the *noſe* are generally cured by the dry future; but where the wound divides the cartilage, and penetrates ſo deep that the ſips of it cannot be kept in contact by the application of ſticking plaiſters, the true future muſt be made through the ſkin, on each ſide of the wound; and Bleyny affirms, that when a part of the *noſe* has been actually cut off, and ſeparated from the reſt, it has been afterwards united, by means of futures. When the naſal bones have been fractured, it is uſual to place ſmall tubes of lead or ſilver under them for ſome time, leſt the paſſage of the *noſe* ſhould be ſtopped up by the ſhooting of new fleſh. Externally ſome vulnerary balſam, or glutinous powder, is to be uſed, and covered with ſticking plaiſters, which muſt be kept on by the four-headed bandage. Heiſter.

NOSE-*band*, in the *Manage*, called in French *muſerelle*, is that part of the head-ſtall of a bridle that comes over a horſe's noſe.

NOSE-*bleed*, in *Botany*. See YARROW.

NOSOCOMIUM, Νοσοκομεῖον, an hoſpital, or infirmary, for the reception of the diſeaſed.

NOSOLOGY, Νοσολογία, compounded of νόσος, *malady, diſeaſe*, and λόγος, *diſcourſe, reaſon*, a diſcourſe or treatiſe of diſeaſes; otherwiſe called PATHOLOGY.

The importance of a comprehenſive and accurate *noſology* has been long and generally allowed: Baglivi, Boerhaave, Gorter, Gaubius, and Sydenham, have expreſſed their deſire of a work of this kind, the great object of which is to fix pathognomonics to every diſeaſe; or in which all diſeaſes are diſpoſed into certain claſſes, orders, and genera, founded on diſtinctions taken from the ſymptoms only, without regard to remote or proximate cauſes.

Felix Platerus, in his Praxis Medica, publiſhed in 1602, gave an imperfect ſketch of a *noſology* of this kind; but no writer ventured to purſue his idea for more than a century after his time. At length, M. Sauvages of Montpelier, publiſhed in 1731, in duodecimo, the outlines of ſuch a work, under the title of Nouvelles Claſſes des Maladies, in which he profeſſes to define diſeaſes from their conſtant and evident ſymptoms only. In 1763 this work was augmented, by the additions of the ſpecies under each genus, into two volumes, in octavo; and afterwards enlarged into two quarto volumes, and publiſhed after his death in 1768. The celebrated Linnæus adopted his plan, and framed a ſyſtem of inſtitutes, under the title of Genera Morborum: his ſcheme was firſt publiſhed in a theſis in 1759, and in a ſmall quarto, in 1763. In the claſſification of diſeaſes, he has nearly retained the arrangement of M. Sauvages, but he has altered the terms, changed the order of the claſſes, and added a new claſs, with which he begins his method. The number of claſſes is eleven, and they are as follow: 1. Exanthematici, or fevers attended with eruptions on the ſkin, comprehending three genera, viz. contagioſi, with ſix ſpecies; ſporadici, with three ſpecies; and ſaltuarii, affecting a part of the body only, to which he has reduced only one ſpecies. 2. Critici, or critical fevers, including three genera, viz. the continentes, with four ſpecies; the intermittentes,

mittentes, with five species; and the exacerbantes, or remitting, with five species. 3. Phlogistici, or inflammations, containing three genera, viz. the membranacei, with seven species; the parenchymatici, or viscerali, with seven species; and the musculosi, or muscular, with one species. 4. Dolores, or painful diseases, comprehending two genera, viz. intrinseci, or of the internal parts, with twenty species; and extrinseci, or of the limbs, with five species. 5. Mentales, or diseases in which the functions of the mind are disturbed, comprehending three genera, viz. ideales, in which the judgment is principally affected, with seven species; imaginarii, affecting the imagination, with six species; and pathetici, in which the appetites and passions are principally affected, with twelve species. 6. Quietales, or diseases in which the voluntary and involuntary motions, and the senses, suffer a diminution, including three genera, viz. defectivi, or defects of the vital powers, with six species; soporosi, or diminished sense and motion, with ten species; and privativi, or diminutions of the senses, with fifteen species. 7. Motorii, or spasmodic diseases, containing two genera, viz. spastici, spastic, or tonic diseases, with ten species; and agitatorii, or convulsive, with fifteen species. 8. Suppressorii, or diseases arising from, or attended with oppression of the organs and impeded excretions, comprehending two genera, viz. suffocatorii, with eighteen species; and constrictorii, with eight species. 9. Evacuatorii, or diseases attended with increased excretion and discharges, comprehending five genera, viz. capitis, of the head, with six species; thoracis, of the breast, with four species; abdominis, of the belly, with fourteen species; genitalium, of the genital passages, with eleven species; and corporis externi, of the external parts, with two species. 10. Deformes, or diseases occasioning external deformity of the body, comprehending three genera, viz. emaciantes, emaciating, with five species; tumidosi, enlarging the body, with eight species; and decolores, such as deform, or change the colour of the skin, with five species. 11. Vitia, or cutaneous, external, or palpable diseases, including eight genera, viz. humoralia, those attended with vitiated or extravasated fluids, with nine species; dialytica, solutions of continuity, as fractures, wounds, &c. with fourteen species; exulcerationes, ulcers, with thirteen species; scabies, cutaneous, with nineteen species; tumores, tumors, with ten species; procidentiæ, tumors arising from dislocation of fleshy or membranous parts, with eight species; deformationes, distortions of particular parts, and other deformities, with eighteen species; and maculæ, blemishes on the skin, with nine species.

The symptomatic plan of arranging diseases has since been followed by some other professors of physic. Dr. Vogel of Gottingen, in 1764, published his Definitiones Generum Morborum; Dr. Cullen of Edinburgh has also published a Synopsis Nosologiæ Methodicæ, and made it the basis of his First Lines of the Practice of Physic; in which, by omitting many genera, and reducing others to the rank of species only, he has very considerably abridged the whole. In 1776, Dr. Sagar, at Iglaw, in Moravia, published a Systema Morborum Symptomaticum, octavo, which is an useful abridgment of the work of M. Sauvages, with some alterations and additions.

NOSTOCH, the name of a vegetable substance which seems to differ from most of the other bodies of that kind, in several particulars.

It is a substance of an irregular figure, of a greenish brown colour, and somewhat transparent. It trembles at the touch, in the manner of a jelly, but it does not melt when held in the hand. It has therefore somewhat of the character of a vegetable leaf, but it has neither veins nor fibres.

It is found in all sorts of soils, but most frequently in sandy ones, sometimes on the gravel of garden walks, and most usually makes its appearance after rain. It is found only in the summer months, and retains its humidity and perfect figure so long as it is a moist season; but immediately dries up, and withers away, on the sun or winds affecting it.

Many people have supposed this not to be a plant; it appears all on a sudden, and, as it were, by a sort of miracle, either from the earth or clouds, and some have called it *flower of earth*, others *flower of heaven*; and the obscurity of its origin has occasioned its being held in great esteem among the chemists, who suppose that it contains an universal spirit capable of converting other metals into gold. Memoires Acad. Par. 1722.

If the *nostoch* has truly no roots, as appears to be very evidently the case, it follows, that it imbibes its nourishment in the manner of the sea-plants, which imbibe the water by which they are nourished at all their pores.

It should seem that there are two species of this *nostoch*, the one only a plain flat leaf; the other curled, wrinkled, and variously undulated; and it is on this last, that the fruits which produce the young plants are principally found. It may be, however, that the one of these may be the male, and the other the female of the same species, as in many larger plants; or possibly the being in the state of fructification alone may make the difference.

NOSTRILS, *nares*, the two apertures or cavities of the nose, through which the air passes, and which serve to convey odours, and to carry off the pituita separated in the sinus of the base of the cranium.

The *nostrils* are separated by a cartilage called *septum narium*, and lined with a very sensible membrane. See SMELLING.

Cicero observes, that the situation of the *nostrils* so near the mouth is very convenient, as the judging of the smells of meat and drinks is a great part of their office: he adds, that their erect position argues the Creator's wisdom; in regard all odours rise from below upwards.

The *nostrils* are sometimes subject to be preternaturally closed; though this is a case that but rarely happens. It is sometimes owing to a careless treatment in the small-pox, in the bad kind of which the *nostrils* have been known to close, and adhere so strongly to the upper lip, which is found turned back at the same time, as to leave no possibility of shutting the mouth. In this unhappy case, the only relief is by the knife, separating the lip from the nose, and then opening a passage through each of the *nostrils*. These are to be kept open, either with tents, or leaden pipes, and the lip pressed downward into its natural position by a compress and bandage, and this continued till the wounds are cicatrized. Heister.

NOSTRILS, *slitting the*, &c. in *Law*. See MAIHM.

NOSTRILS *of birds* are the nice instruments with which they are furnished for distinguishing their food: these are placed either in the middle of the upper mandible, or near the base, or at the base, or behind the base. Some birds have no *nostrils*. They are generally naked, but sometimes covered with bristles reflected over them, or hid in the feathers.

NOSTRILS *of fish*. See NARES *piscium*.

NOSUS, a name by which some of the barbarous writers of the middle ages have called *alabaster*: others also have called it *nisus*.

NOT *guilty*, the general issue or plea of the defendant, in any criminal action. See NON *est culpabilis*.

NOTABILIA *bona*. See BONA.

NOTARICON, the third part or species of the Jewish CABBALA.

Rabbi Nathan, in his Great Aruch, says, that *notaricon* is when a single letter is taken for the sign of a thing, i. e. for a whole name. He adds, that the word comes from the Latin *notarius*, a person who writes in notes, or short-hand; and R. Elias Levita gives the same account in his Thesbites; except that, in lieu of one letter for a word, he mentions two or three.

But, after all, neither the one nor the other seems alone sufficient; for, as a single letter frequently makes a word, so, in the *notaricon*, a whole word sometimes stands for a single letter.
